From other species of pine in different parts of Europe, a similar product is obtained and sold by the same name. It is prepared by removing the juice which concretes upon the bark of the tree or upon the surface of incisions, called *galipot* by the French, and purifying it by melting and straining, either through cloth or a layer of straw.

A factitious Burgundy pitch is also made by melting together common pitch, resin, and turpentine, and agitating the mixture with water, which gives it the requisite yellowish colour. Its odour is different from that of the genuine.

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state it is hard, brittle, quite opaque, of a yellowish or brownish-yellow colour, and a weak terebinthinate taste and odour. It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of essential oil.

Under the name of ABIETIS RESINA, the London College directs the concrete juice of the *spruce fir*, as taken immediately from the bark of the tree, without any preparation. It is the *Thus* or *Frankincense* of the former London and present Dublin Pharmacopœia. It is in solid brittle tears, of a brownish-yellow colour on the outside, and paler within, and emits an agreeable odour when burned. It softens and becomes adhesive at the temperature of the body. Though ascribed to the *Abies excelsa*, it is pro-

bably obtained also from other sources; and we have been told by an apothecary from London, that an article exactly resembling our common white turpentine when perfectly dried, is sold as frankincense in the shops of that city.

Medical Properties and Uses. Applied to the skin in the shape of a plaster, Burgundy pitch acts as a gentle rubefacient, producing a slight degree of inflammation and serous effusion without separating the cuticle. Sometimes it excites a papillary or vesicular eruption; and we have known it to act upon the surface as a violent poison, giving rise to excessive pain, tumefaction, and redness, followed by vesication and even ulceration. It is used chiefly in cases of slight chronic pains of a rheumatic character, or in chronic affections of the chest or abdominal viscera, which call for a gentle but long continued revulsive action upon the skin.

The resin of the spruce fir (*Abietis Resina*) is used only as an ingredient of plasters.

PIX CANADENSIS. *U. S.*

Canada Pitch.

“The prepared concrete juice of *Abies Canadensis*.” *U. S.*

ABIES. See **PIX BURGUNDICA.**

Abies Canadensis. Michaux, *N. Am. Sylv.* iii. 185.—*Pinus Canadensis.* Willd. *Sp. Plant.* iv. 505. This is the *hemlock spruce* of the United States and Canada. When of full growth it is often seventy or eighty feet high, with a trunk two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. The branches are slender, and dependent at their extremities. The leaves are very numerous, six or eight lines long, flat, denticulate, and irregularly arranged in two rows. The strobiles are ovate, little longer than the leaves, pendulous, and situated at the ends of the branches.

The tree is abundant in Canada, Nova Scotia, and the more northern parts of New England; and is found in the elevated and mountainous regions of the Middle States. Its bark abounds in the astringent principle, and is much used for tanning in the northern parts of the United States. It contains much less juice than some other of the *Pinaceæ*; and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about or have begun to decay, the juice exudes spontaneously, and hardens upon the bark in consequence of the partial evaporation or oxidation of its essential oil. The bark thus incrustrated is stripped from the tree, broken into pieces of convenient size, and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. It is brought to Philadelphia from the north of Pennsylvania, in dark coloured brittle masses, which on being broken exhibit numerous minute fragments of bark, interspersed through their substance. From these it is purified in the shops by melting and straining through linen or canvass. (*Ellis, Journ. of Phil. Col. of Pharm.* ii. 18.)

Thus prepared it is hard, brittle, quite opaque, of a dark yellowish-brown

colour, which becomes still darker by exposure to the air, of a weak peculiar odour, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and melts at 198° F. Its constituents are resin and a minute proportion of essential oil. It is most generally known by the incorrect name of *hemlock gum*, and in the former edition of the U. S. Pharmacopœia was named *hemlock pitch*.

Medical Properties and Uses. Hemlock pitch is a gentle rubefacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. W.

PIX LIQUIDA. U.S., Lond., Ed., Dub.

Tar.

“The impure turpentine procured by burning from the wood of *Pinus palustris* and other species of *Pinus*.” U. S. “*Pinus sylvestris. Resina præparata liquida.*” Lond. “Tar from various species of *Pinus* and *Abies*.” Ed. “E speciebus *Pini* diversis.” Dub.

Goudron, *Fr.*; Theer, *Germ.*; Pece liquida, *Ital.*; Alquitran, *Span.*

The tar used in this country is prepared from the wood of various species of pine, particularly the *Pinus palustris* of the Southern States, the *P. australis* of Michaux. (See *Terebinthina*.) The dead wood is usually selected, because, when vegetation ceases, the resinous matter becomes concentrated in the interior layers. The wood is cut into billets of a convenient size, which are placed together so as to form a large stack or pile, and then covered with earth as in the process for making charcoal. The stack is built upon a small circular mound of earth previously prepared, the summit of which gradually declines from the circumference to the centre, where a small cavity is formed, communicating by a conduit with a shallow ditch surrounding the mound. Fire is applied through an opening in the top of the pile, and a slow combustion is maintained, so that the resinous matter may be melted by the heat. This runs into the cavity in the centre of the mound, and passes thence by the conduit into the ditch, whence it is transferred into barrels. Immense quantities of tar are thus prepared in North Carolina and the south-eastern parts of Virginia, sufficient, after supplying our own consumption, to afford a large surplus for exportation.

Considerable quantities of tar are also prepared in the lower parts of New Jersey, in some portions of New England, and in Pennsylvania west of the Alleghany mountains, from the *Pinus rigida*, or pitch pine, and perhaps from some other species.

Properties. Tar has a peculiar empyreumatic odour, a bitterish, resinous somewhat acid taste, a colour almost black, and a tenacious consistence intermediate between that of a liquid and solid. It consists of resinous matter, united with acetic acid, oil of turpentine, and various volatile empyreumatic products, and coloured with charcoal. By distillation it yields an acid liquor called *pyroligneous acid* (see *Acidum Pyroligneum*), and an empyreumatic oil called *oil of tar*; and what is left behind is *pitch*. The empyreumatic oil has been ascertained by Dr. Reichenbach, of Moravia, to contain, besides oil of turpentine, six distinct principles, which he has named *paraffine*, *eupione*, *creasote*, *picamar*, *capnomor*, and *pittacal*. Of these only *picamar* and *creasote* merit particular attention; the former as the principle to which tar owes its bitterness, the latter as the one upon which it probably depends chiefly for its medical virtues. (See *Creasotum*.) Tar

yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water*. It is dissolved by alcohol, ether, and the volatile and fixed oils.

Medical Properties and Uses. The medical properties of tar are similar to those of the turpentine. It is sometimes used in chronic coughs, and, when the disease depends on chronic bronchial inflammation, with occasional advantage. Little benefit can be expected from it in genuine phthisis, in the treatment of which it was formerly highly recommended. Dr. Bate-man employed it advantageously as an internal remedy in ichthyosis. Its vapour, inhaled into the lungs, has been found serviceable in numerous cases of bronchial disease. Externally applied, in the state of ointment, it is a very efficient remedy in tinea capitis, or scald head, and in some cases of psoriasis; and has been used with advantage in foul or indolent ulcers, and some other affections of the skin.

It may be used in the form of tar water (*Aqua Picis Liquidæ*), or in substance made into pills with wheat flour, or mixed with sugar in the form of an electuary. The dose is from half a drachm to a drachm, and may be repeated so as to amount to three or four drachms daily.

PLUMBUM.

Lead.

Plomb, Fr.; Blei, Germ.; Lood, Dutch.; Plombo, Ital.; Plomo, Span.; Chumbo, Port.

Lead is not officinal in its metallic state; but enters into a number of important medicinal preparations. It occurs in nature in three principal states—as an oxide, as a sulphuret called *galena*, and in the saline state, forming the native sulphate, phosphate, carbonate, chromate, molybdate, tungstate, and arseniate of lead. The oxide is rare, but *galena* is exceedingly abundant and diffused, and is the ore from which all the lead of commerce is extracted. The process of extraction consists merely in melting the ore in contact with charcoal. Mines of *galena* occur in different parts of the world, but the richest and most extensive are found in our own country. The lead

region of the United States extends in length from the Wisconsin in the north, to the Red river of Arkansas in the south, and in breadth about one hundred and fifty miles. It is only of latter years that these mines have been extensively worked.

Properties. Lead is a soft, bluish-gray, and very malleable metal, presenting a bright surface when newly melted or cut. It has a perceptible taste, and a peculiar smell when rubbed. It undergoes but little change in the air, but is corroded by the combined action of air and water. Its sp. gr. is 11.4, melting point about 612° , and equivalent number 103.6. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame, throwing off dense yellow fumes. The best solvent of lead is nitric acid; but the presence of sulphuric acid destroys, and that of muriatic acid lessens its solvent power, on account of the insolubility of the compounds which these acids form with the metal. Lead forms five oxides, a dinoxide, protoxide, sesquioxide, deutoxide, and red oxide. The *dinoxide* consists of two equivalents of lead and one of oxygen. The *protoxide*, called in commerce *massicot*, may be obtained by calcining, in a platinum crucible, the subnitrate of lead, formed by precipitating a solution of the nitrate by ammonia. On a large scale it is manufactured by exposing melted lead to the action of the air. Its surface becomes incrustated with a gray pellicle, which, being scraped off, is quickly succeeded by another; and the whole of the metal, being in this way successively presented to the air, becomes converted into a greenish-gray powder, consisting of protoxide and metallic lead. This, by exposure to a moderate heat, absorbs more oxygen, and is converted entirely into protoxide. This oxide has a yellow colour, and is the one present in the salts of lead. As a hydrate it is officinal with the London College. (See *Plumbi Oxydum Hydratum*.) It consists of one equiv. of lead 103.6, and one of oxygen $8=111.6$. A variety of the protoxide, called *litharge*, is very much used in pharmacy, and is officinal in all the Pharmacopœias. (See *Plumbi Oxidum Semivitreum*.) The *sesquioxide*, recently discovered by Winkelblech, is unimportant. The *deutoxide*, called also *puce oxide* from its *flea*-brown colour, may be obtained by treating red lead with nitric acid. The acid takes up the protoxide, and leaves the deutoxide, which may be purified by washing with boiling water. It is a tasteless powder, of a dark-brown colour. When heated to redness it loses half its oxygen, and becomes protoxide. It consists of one equiv. of lead 103.6, and two of oxygen $16=119.6$. The *red oxide*, called in commerce *minium*, or *red lead*, is described under another head. (See *Plumbi Oxidum Rubrum*.) Lead combines with chlorine and iodine, forming officinal preparations. (See *Plumbi Chloridum* and *Plumbi Iodidum*.) The acetate, carbonate, and nitrate are also officinal.

The best tests of this metal are sulphuretted hydrogen, and a solution of iodide of potassium. The former produces a dark-brown precipitate of sulphuret of lead, the latter, a yellow one of iodide of lead.

Medical Properties and Uses. The effects of lead in its various combinations are those of a sedative and astringent. It is used internally for the purpose of reducing vascular action, and restraining inordinate discharges; and externally as an abater of inflammation. When introduced into the system in a gradual manner, either by working in the metal, or by taking it in small and frequently repeated doses, it acts injuriously on the nervous system, producing a peculiar colic, called *lead colic*, sometimes apoplectic symptoms, and palsy which is almost always partial and incomplete, and affects for the most part the upper extremities. Occasionally salivation is produced, and, according to Dr. Henry Burton, the constitutional effects of

the metal are indicated by a narrow lead-blue line at the edge of the gum, round two or more of the teeth, as a constant and early sign. The treatment of lead colic is mentioned under *carbonate of lead*. Lead palsy is usually attended with dyspepsia, constipation, tendency to colic, lassitude, and gloominess of mind; and is best treated by tonics, aperients, exercise, and avoidance of the cause of the disease. The poisonous effects of an overdose of the lead preparations are to be combated by emetics, if free vomiting has not previously occurred, by the exhibition of the sulphate of magnesia or sulphate of soda, to act as an antidote by forming the inert sulphate of lead, and by opium.

Orfila has determined, by experiments on dogs, the appearance exhibited by the mucous membrane of the stomach after the use of small doses of the salts of lead. After the action of such doses for two hours, dull white points are visible on the membrane, sometimes in rows and sometimes disseminated, and evidently consisting of the metal, united with the organic tissue. If the animal be allowed to live for four days, the same spots may be seen with the magnifier, and if sulphuretted hydrogen be applied to the membrane, they are instantly blackened. (*Archives Gén. 3ème Série, iv. 244.*)

According to M. Gendrin, sulphuric acid, prepared like lemonade, and used both internally and externally, is a prophylactic against the poisonous effects of lead, especially the lead colic. (*Am. Journ. of Med. Sci. xv. 528.*) It may be supposed to act by forming the inert sulphate with the poison. Mr. Benson, a manager of white lead works at Birmingham, has tried this acid, and finds it an effectual preventive of lead colic in his establishment, where it was exceedingly prevalent before its employment. He uses it as an addition to ginger beer, to which bicarbonate of soda is also added to render it brisk, but not in sufficient quantity to prevent a considerable portion of the acid remaining in excess. (*London Lancet, Dec. 1842.*) On the other hand, the powers of sulphuric acid in preventing the poisonous effects of lead are positively denied by Dr. A. Grisolle. This writer recommends that workmen employed in lead manufactories should use frequent baths, avoid intemperance, and always eat before they enter upon their work in the morning. He supposes that in the great majority of cases the metal is introduced into the system through the stomach by means of the saliva or food.

Acetate of Lead.

Sugar of lead; Saccharum Saturni, Cerussa acetata, *Lat.*; Acétate de plomb, Sucre de plomb, Sel de Saturne, *Fr.*; Essigsauers Bleioxyd, Bleizucker, *Germ.*; Zucchero di Saturno, *Ital.*; Azucar de plomo, *Span.*

Directions are given by the three British Colleges for preparing acetate of lead; but as it is seldom or never prepared by the apothecary, and may be obtained in the greatest perfection, and at a cheap rate, from the manufacturing chemist, it is more properly placed, in the United States Pharmacopœia, in the catalogue of the Materia Medica.

Preparation. Sugar of lead is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar; and they are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal becomes protoxidized, and dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving, by the assistance of heat, litharge, or the protoxide of lead obtained by calcination, in an excess of distilled vinegar or purified pyroligneous acid, contained in leaden boilers. The oxide is quickly dissolved, and when the vinegar has become saturated, the solution is transferred to other vessels to cool and crystallize. The crystals having formed, the mother waters are decanted, and, by a new evaporation, made to yield a new crop. These are generally of a yellow colour, but may be purified by repeated solutions and crystallizations.

The London College directs this salt to be formed by dissolving litharge, by the aid of a gentle heat, in dilute acetic acid. The Edinburgh process is substantially the same as the London; the pyroligneous acid directed being in fact acetic acid of medium strength. The process of the Dublin College directs the solution of carbonate of lead (white lead) in the acid, but is ineligible on account of its expense.

Sugar of lead is extensively manufactured in Germany, Holland, France, and England, as well as in the United States; its principal consumption being caused by the arts of dyeing and calico-printing, in which it is employed to form with alum the acetate of alumina, which is used as a mordant.

Properties. Acetate of lead is a white salt, crystallized in brilliant needles, which have the shape of long prisms, terminated by dihedral summits. Its

taste is at first sweet and afterwards astringent. Exposed to the air, it effloresces slowly. It dissolves in four times its weight of cold, and in a much smaller quantity of boiling water. It is soluble also in alcohol. Its solution in common water is turbid, in consequence of the formation of carbonate of lead with the carbonic acid which such water always contains. This turbidness may be removed by the addition of a small portion of vinegar, or of dilute acetic acid. In pure distilled water, free from carbonic acid, it ought to dissolve entirely, and form a clear solution. Sulphuric acid or a soluble sulphate, when added to a solution of acetate of lead, produces instantly a precipitate of sulphate of lead; the acid, at the same time, disengaging vapours having the smell of vinegar. The salt, when heated, first fuses and parts with its water of crystallization, and afterwards is decomposed, yielding acetic acid and pyroacetic spirit (acetone), and leaving a residue of charcoal and reduced lead. An important property of sugar of lead is its power of dissolving a large quantity of protoxide of lead. (See *Liquor Plumbi Subacetatis*.) It consists of one equiv. of acetic acid 51·48, one of protoxide of lead 111·6, and three of water 27 = 190·08.

Incompatibles. Acetate of lead is decomposed by all acids, and by those soluble salts, the acids of which produce with protoxide of lead insoluble or sparingly soluble compounds. Acids of this character are the sulphuric, muriatic, citric, and tartaric. It is also decomposed by lime-water, and by ammonia, potassa, and soda; the last two, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the sulphate of lime and common salt, which such water usually contains. With sulphuretted hydrogen, it gives a black precipitate of sulphuret of lead; with iodide of potassium, a yellow one of iodide of lead; and with carbonate of soda, a white one of carbonate of lead.

Medical Properties and Uses. Acetate of lead, in medicinal doses, is a powerful astringent and sedative; in large ones, an irritant poison. The danger, however, from over-doses of sugar of lead is not so great as is generally supposed. It has sometimes been given in pretty large doses in regular practice, without any bad effects, and cases are on record where a quarter of an ounce has been swallowed without proving fatal. It may be remarked, however, that the immediate effects of an over-dose are often escaped by prompt and spontaneous vomiting; and that the remote constitutional effects are not apt to occur, so long as the evacuations from the bowels are not materially diminished. The principal diseases in which it has been exhibited are hemorrhages, particularly from the lungs, intestines, and uterus. Its effect in restraining the discharge of blood is admitted to be very powerful. It has also been used with advantage in certain forms of dysentery and diarrhœa, and has been recommended in particular stages of cholera infantum. Combined with opium it is well suited to the treatment of the diarrhœa occurring in phthisis. It sometimes proves a valuable remedy in checking vomiting. Dr. Irvine, of Charleston, recommends it to compose the irritability of the stomach in yellow fever; and Dr. Davis of Columbia, S. C., used it with benefit in the irritable stomach attendant on bilious fever. It has been much extolled by the German practitioners in dothineritis, or the typhoid fever attended with ulcerations of the intestines. In some of these cases it was advantageously combined with carbonate of ammonia. The same practitioners have strongly recommended it in aneurism of the aorta, and Dupuytren, on their report of its efficacy, tried it in several cases, and with marked results, in diminishing the size of the aneurismal tumour. (*Archives Gén. 3ème Série, v. 445.*) One of the authors of this Dispensatory has imitated the practice in aneurism of the

aorta, and in enlargement of the heart, and with encouraging results. In mercurial salivation, M. Brachet, of Lyons, found sugar of lead very efficacious, administered in grain pills, night and morning. Several cases of severe salivation of several months' duration, which had resisted the use of opium, purgatives, &c. were speedily relieved by the remedy. The solution is frequently used as a collyrium; and applied by means of cloths, or mixed with crumb of bread, it forms a good application to superficial inflammation. For the latter purpose, the dilute solution of subacetate of lead is generally preferred. (See *Liquor Plumbi Subacetatis Dilutus*.)

When employing this medicine, the practitioner should always bear in mind that, when long continued in small doses, it is apt to produce dangerous constitutional effects. These effects are chiefly of two kinds; 1. an affection of the alimentary canal, attended with severe pain and obstinate constipation, called *colica piftonum* or *lead colic*; 2. a chronic affection of the muscles, especially of the extensors of the upper extremities, characterized by an excessive wasting of these organs, and denominated *lead palsy*. Both these affections are apt to be excited in those artisans who work in lead. The approach of these dangerous constitutional symptoms is said to be indicated by a narrow lead-blue line at the edge of the gums. (See page 548.)

The dose of sugar of lead is from one to three grains, in the form of pill, repeated every two or three hours. It is generally given combined with opium. The solution for external use may be made by dissolving from two to three drachms of the salt in a pint of water; and if it be wanted clear, a fluidrachm of vinegar or dilute acetic acid may be added, which immediately dissolves the carbonate of lead, to which its turbidness is owing. The usual strength of the solution as a collyrium is from one to two grains to the fluidounce of distilled water.

PLUMBI CARBONAS. *U. S., Lond., Ed.*

Carbonate of Lead.

Off. Syn. PLUMBI CARBONAS. CERUSSA. *Dub.*

White lead, Ceruse; Céruse, Carbonate de plomb, Blanc de plomb, Blanc de céruse, *Fr.*; Bleiweiss, *Germ.*; Cerussa, *Lat., Ital.*; Albayalde, *Span.*

Preparation. Carbonate of lead is prepared by two principal methods. By one method it is obtained by passing a stream of carbonic acid through a solution of subacetate (trisacetate) of lead. The carbonic acid combines with the excess of protoxide and precipitates as carbonate of lead, while a neutral acetate remains in solution. This, by being boiled with a fresh portion of protoxide, is again brought to the state of subacetate, when it is treated with carbonic acid as before. In this way the same portion of acetate repeatedly serves the purpose of being converted into subacetate, and of being decomposed by carbonic acid. The carbonate obtained is washed, dried by a gentle heat, and thrown into commerce. This process, which produces white lead of the first quality, was invented and made public by Thenard, about the year 1802, and is that which is usually pursued in France and Sweden.

A modification of the process of Thenard is now pursued by some manu-

facturers in England. Litharge is mixed with a hundredth part of acetate of lead, and the mixture, previously moistened with very little water, is subjected to a stream of carbonic acid. (*Pelouze.*)

The other method, which consists in exposing lead to the vapours of vinegar, originated in Holland, and is pursued in England and the United States; but in England, with some modifications, which are not well known. We shall describe the process as pursued by our own manufacturers. The lead is cast into thin sheets, made by pouring the melted lead over an oblong sheet-iron shovel, with a flat bottom and raised edges on its sides, which is held in a slanting direction over the melting-pot. As many of these sheets are then loosely rolled up as may be sufficient to form a cylinder five or six inches in diameter, and seven or eight high, which is placed in an earthen pot containing about half a pint of vinegar, and having within a few inches from the bottom, three equidistant projecting portions in the earthenware, on which the cylinder of lead is supported, in order to keep it from contact with the vinegar. The pots thus prepared are placed side by side, in horizontal layers, in a building roughly constructed of boards, with interstices between them. The first layer is covered with boards, on which a stratum of tan or refuse straw from the stables is strewed; and fresh layers of pots, boards, and straw, are successively placed, until the whole building is filled. The sides also are enclosed with straw. The pile of pots, called a *bed*, is allowed to remain undisturbed for about six weeks, at the end of which time it is taken down, and the cylinder of lead in each pot, though still retaining its shape, is found almost entirely converted into a flaky, white, friable substance, which is the white lead. This is separated from the lead yet remaining in the metallic state, ground in water, whereby it is washed and reduced to fine powder, and finally dried in long, shallow reservoirs, usually heated by steam.

Pelouze has succeeded in explaining all these processes on the same general principles. In Thenard's process it is admitted, that the same portion of acetate of lead repeatedly unites with protoxide, and gives it up again to carbonic acid to form the carbonate. In the modified English process, he supposes that the one per cent. of acetate of lead combines with sufficient litharge to convert it into subacetate, which immediately returns to the state of neutral acetate, by yielding up its excess of base to form the carbonate with the carbonic acid. The acetate is now ready to combine with a fresh portion of litharge, to be transferred to the carbonic acid as before; and thus this small proportion of acetate, by combining with successive portions of the litharge, finally causes the whole of it to unite with the carbonic acid. In the Dutch process, Pelouze has rendered it almost certain, that none of the oxygen or carbonic acid of the carbonate is derived from the vinegar. Here he supposes that the heat, generated by the fermentation of the straw or tan, volatilizes the vinegar, the acetic acid of which, with the assistance of the oxygen of the air, forms with the lead a small portion of subacetate. This, by reacting with the carbonic acid resulting from the decomposition of the straw or tan, forms carbonate of lead and is reduced to the state of neutral acetate. The neutral acetate returns again to the state of subacetate, and, by alternately combining with and yielding up the protoxide, causes the whole of the lead to be finally converted into carbonate. (*Journ. de Pharm. 3ème Série, i. 51 and 443.*)

The temperature of the beds of pots in the Dutch process, is about 113° . If it falls below 95° , a part of the lead escapes corrosion, and if it rises above 122° the product is yellow. The form of acetic acid usually employed in this process is common vinegar; but the variable nature of that

liquid as to strength and purity is an objection to its use; and, accordingly, other forms of the acid have been substituted for it with advantage, such as the purified acetic acid from wood in a diluted state. For further information in relation to the different processes proposed or pursued for making white lead, the reader is referred to a paper by Prof. J. C. Booth, in the *Journal of the Franklin Institute* for Jan. 1842.

Properties. Carbonate of lead is a heavy, opaque substance, in powder or friable lumps, insoluble in water, of a fine white colour, inodorous and nearly insipid. Its beauty as a pigment depends in a great measure on the purity of the lead from which it is manufactured. It is wholly soluble, with effervescence, in dilute nitric acid. Exposed to heat it becomes yellow, and with charcoal is reduced to the metallic state. It is sometimes adulterated with the sulphates of baryta, lime, and lead. These sulphates, if present, are left undissolved by nitric acid. Chalk or whiting is another adulteration. This may be detected by precipitating the nitric solution of the white lead with sulphuretted hydrogen to remove the lead, and then adding to the boiled and filtered solution oxalate of ammonia, which will cause a precipitate of oxalate of lime; or it may be discovered by adding to the nitric solution an excess of potassa, which will redissolve the protoxide of lead first thrown down, but leave a white powder of lime. Neutral carbonate of lead consists of one eq. of carbonic acid 22.12, and one of protoxide of lead $111.6 = 133.72$. Commercial white lead is generally a mixture in varying proportions of the carbonate and hydrate of lead.

Medical Properties and Uses. White lead is ranked in the *Materia Medica* as an astringent and sedative. It is employed externally only, being used as an application to ulcers, and to inflamed and excoriated surfaces. It has been recommended as an external application in facial neuralgia. (*Journ. de Pharm.* xx. 603.) It is used either by sprinkling the powder on the part, or in the form of ointment. (See *Unguentum Plumbi Carbonatis*.) Its external use, however, is viewed by many practitioners as dangerous, on account of the risk of absorption; but the danger is certainly overrated, as we have the testimony of respectable physicians that they frequently use it in this way, without the least unpleasant result.

Of the different preparations of lead, the carbonate is generally considered to be the most poisonous. Being very extensively manufactured for the purposes of the arts, it is that preparation also which most frequently produces the peculiar spasmodic colic, called *colica pictonum*. This disease is characterized by pain about the region of the navel, and by obstinate constipation, attended with a frequent desire to evacuate the bowels, and is supposed to depend upon a spasmodic constriction of the intestinal tube, particularly of the colon. The principal indications in the treatment are, first to relax the spasm, and then to evacuate the bowels by the gentlest means. Opium and mild aperients, used alternately, are accordingly the best remedies, and among the latter castor oil and sulphate of magnesia are to be preferred. Indeed the latter appears peculiarly adapted to the case; for while it acts as an aperient, it operates as a counterpoison, by forming the inert sulphate of lead with any preparation of the metal which it may meet with in the bowels. Calomel is often useful in particular states of the disease; and if it happen to induce ptyalism, the disease immediately yields.

PLUMBI OXIDUM RUBRUM. U.S., Ed.

Red Oxide of Lead.

Red lead, Minium; Deutoxide de plomb, Oxide rouge de plomb, Minium, *Fr.*; Menig, *Germ.*; Minio, *Ital.*, *Span.*

Preparation. Red lead is prepared on the large scale in a furnace, with the floor slightly concave and the roof arched, presenting a general resemblance to a baker's oven. The lead is placed on the floor, and gradually raised to a red heat, whereby it melts and becomes covered with a pellicle of protoxide, which is removed by means of a long iron scraper; and the pellicles, as they successively form, are scraped off, until the whole of the metal has been converted into them. The product is subjected to further calcination with occasional stirring, for some time, with a view to oxidize any particles of metallic lead. It is thus rendered yellow, and constitutes the *protoxide of lead*, or *massicot*. This is taken out of the furnace and thrown upon a level pavement, and cooled by being sprinkled with water. It is next reduced to fine powder by trituration and levigation, and dried; and in this state is introduced into large, shallow, square tin boxes, which are placed in another furnace, closed from the air, and heated nearly to redness; the heat being allowed gradually to fall during a period of from twenty-four to thirty hours. At the end of this time the protoxide of lead will have combined with an additional quantity of oxygen, and become the red oxide. This is taken out, and, having been passed through a fine wire sieve, is packed in barrels for the purposes of commerce.

The above is an outline of the French process for making red lead. In England and the United States, the calcination of the protoxide is not performed in tin boxes, but by returning it to the furnace in which it was first calcined. To save the first calcination, litharge is generally used for making the red lead of commerce, which consequently is liable to contain the impurities of that substance, consisting of iron, copper, a little silver, and silica. Copper is hurtful in red lead when used for making glass, to which it communicates colour. In order to have red lead of good quality, it should be made in large quantities at a time. It is also important that it be slowly cooled; for as the absorption of oxygen by which it is formed, takes place during a particular interval of temperature only, it is necessary that the heat within that interval should be maintained sufficiently long to allow all the protoxide to absorb its appropriate dose of oxygen. It is said that the finest red lead is procured by calcining the protoxide obtained from the carbonate.

Properties, &c. Red lead is in the form of a heavy, scaly powder, of a bright red colour, with a slight shade of orange. Its sp. gr. is about 9. When exposed to heat it gives off oxygen, and is reduced to the state of protoxide. It is sometimes adulterated with red oxide of iron, or red bole, substances which may be detected by dissolving the suspected red lead in nitric acid, and testing with tincture of galls. This reagent will produce a black precipitate, in consequence of the iron present in the substances mentioned. If brick-dust be present, it will be left undissolved upon treating the suspected specimen with muriatic acid. When free from impurities, it is completely reduced on charcoal, by means of the blowpipe, into a globule of metallic lead. It is completely soluble in highly fuming nitrous acid. (*Ed. Pharm.*) The resulting solution is one of the nitrate of the protoxide, formed by a transfer of the excess of oxygen in the red lead to the nitrous

acid, which is thus converted into the nitric. When treated by nitric acid, it is resolved into protoxide which dissolves, and deutoxide which remains, in the form of a deep-brown powder.

The red lead of commerce may be considered as a mixture of what may be called the true red oxide, and variable proportions of protoxide. That this is its nature is proved by the action of cold dilute acetic acid, not used in excess, which takes up a variable quantity of protoxide, leaving a portion unchanged in colour, which may be deemed the pure red oxide. This latter, when analyzed by nitric acid, has been proved, by the coincident results of Dalton, Dumas, and Phillips, to consist of two equiv. of protoxide, and one of deutoxide, corresponding with three equiv. of lead, and four of oxygen.

Red lead enters into no officinal preparation. It is employed in preparing Acidum Aceticum, *U. S.*, *Ed.*, and Chlorinei Aqua, *Ed.* It is used in the arts chiefly as a paint and as an ingredient in flint glass. B.

PLUMBI OXIDUM SEMIVITREUM. *U. S.*

Semivitrified Oxide of Lead.

Off. Syn. PLUMBI OXYDUM. Plumbi Oxydum (*semivitreum*). *Lond.*; LITHARGYRUM. *Ed.*; PLUMBI OXYDUM SEMIVITREUM. LITHARGYRUM. *Dub.*

Litharge; Oxide de plomb fondu, *Litharge, Fr.*; Bleiglätte, *Germ.*; Litargirio, *Ital.*; Almartaga, *Span.*

When the protoxide of lead is rendered semi-crystalline by incomplete fusion, it becomes the semivitrified oxide, or litharge. Almost all the litharge of commerce is obtained, as a secondary product, in the process for extracting silver from argentiferous galenas. After extracting the argentiferous lead from the ore, the alloy is calcined in the open air; whereupon the lead becomes oxidized, and by fusion passes into the state of litharge, while the silver remains behind. The following is an outline of the process. The lead containing the silver is placed upon an oval slightly excavated dish, about three feet long and twenty inches wide, called a *test*, made by beating pulverized bone-earth formed into a paste with water, into a mould, the sides of which are formed of an elliptical band of iron, and the bottom, of strips of sheet iron, placed a short distance apart. The test is of such a size as exactly to fit an opening in the floor of a reverberatory furnace, where it is placed, and adjusted to the level of the floor. On one side of the test the fire-place is situated, and exactly opposite, the chimney; while at one extremity of it the pipe of a strong bellows is placed, and at the other a vertical hole is made, communicating with a gutter leading from the centre of the test. The furnace is now lighted, and shortly afterwards the bellows is put in motion. The lead fuses and combines with oxygen, and the resulting oxide melting also, forms a stratum which swims on the surface, and which is driven by the blast of the bellows along the gutter, and through the vertical hole, into a recipient below, where, upon solidifying, it crystallizes in small scales, which form the litharge. In proportion as the lead is oxidized and blown off the test, fresh portions are added, so as to keep it always sufficiently full. The process is continued for eight or ten days, after which no more lead is added. The operation is now confined to the metal remaining on the test; and, the oxidizement proceeding, a period at last arrives when the whole of the lead has run off as litharge, and the silver, known to be pure by its brilliant appearance in the fused state, alone

remains. This is then removed, and the process repeated on a fresh portion of argentiferous lead.

Properties. Litharge is in the form of small, brilliant, vitrified scales, some presenting a red, and some a yellow colour. In mass it has a foliaceous structure. It is devoid of taste or smell. It slowly attracts carbonic acid from the air, and contains more of this acid the longer it has been prepared. It is on this account that it commonly effervesces slightly with the dilute acids. It has the property of decolorizing wines, when agitated with them. When heated with the fats and oils, in connexion with water, it saponifies them. (See *Emplastrum Plumbi*.) In dilute nitric acid it should be almost entirely soluble. As it occurs in commerce, it usually contains iron, copper, and a little silver and silica. The English litharge is most esteemed; that from Germany being generally contaminated with iron and copper. In choosing litharge, samples should be selected which are free from copper, and from fragments of vegetable matter. This metal is detected, if upon adding ferrocyanuret of potassium to a nitric solution of the litharge, a brown instead of a white precipitate is produced. Two varieties of litharge are distinguished in commerce, named from their colour, and dependent on differences in the process for making it. Sometimes it has a pale yellow colour and silvery appearance, and is then denominated *silver litharge*, or *yellow litharge*; at other times it is of a red colour, and is known under the name of *gold litharge*, or *red litharge*. The latter owes its colour to the presence of a portion of red lead. In composition, litharge is essentially identical with the protoxide of lead. (See *Plumbum*.) The carbonic acid which it contains is variable, dependent on the length of time it has been prepared; but its average amount is about four per cent.

Pharmaceutical Uses, &c. Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, which are used for abating inflammation, and for other purposes. Combined with olive oil it forms the *Emplastrum Plumbi*, which is the basis of many of the preparations technically called *Plasters*. (See *Emplastra*.) In the arts it is extensively employed in the glazing of pottery, in painting to render oils drying, and as an ingredient in flint glass.

PODOPHYLLUM. U. S.

May-apple.

“The rhizoma of *Podophyllum peltatum*.” *U. S.*

PODOPHYLLUM. *Sex. Syst.* Polyandria Monogynia.—*Nat. Ord.* Ranuncul, *Juss.*; Podophylleæ, *Lindley*.

Gen. Ch. Calyx three-leaved. Corolla nine-petalled. Berry one-celled, crowned with the stigma. *Willd.*

Podophyllum peltatum. Willd. *Sp. Plant.* ii. 1141; Bigelow, *Am. Med. Bot.* ii. 34; Barton, *Med. Bot.* ii. 9. The may-apple, known also by the name of *mandrake*, is an indigenous herbaceous plant, and the only species belonging to the genus. The root (rhizoma) is perennial, creeping, usually several feet in length, about one quarter of an inch thick, of a brown colour externally, smooth, jointed, and furnished with radicles at the joints. The stem is about a foot high, erect, round, smooth, divided at top into two

petioles, and supporting at the fork a solitary one-flowered peduncle. Each petiole bears a large peltate, palmate leaf, with six or seven wedge-shaped lobes, irregularly incised at the extremity, yellowish-green on their upper surface, paler and slightly pubescent beneath. The flower is nodding. The calyx is composed of three oval, obtuse, concave, deciduous leaves. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong yellow anthers of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are imbedded. It is, when ripe, of a lemon-yellow colour, interrupted by round brownish spots.

The plant is extensively diffused throughout the United States, growing luxuriantly in moist shady woods, and in low marshy grounds. It is propagated by its creeping root, and is often found in large patches. The flowers appear about the end of May and beginning of June; and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its colour and shape it is sometimes called *wild lemon*. The root is the officinal portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

Properties. The dried root is in pieces about two lines in thickness, with swelling, broad, flattened joints at short intervals. It is much wrinkled lengthwise, is yellowish or reddish-brown externally, and furnished with fibres of a similar, but somewhat paler colour. The fracture is short and irregular, and the internal colour whitish. The powder is light yellowish-gray, resembling that of jalap. The root in its aggregate state is nearly inodorous; but in powder has a sweetish not unpleasant smell. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid. The decoction and tincture are bitter. A peculiar bitter principle was discovered in the root by William Hodgson, jun. of Philadelphia. It is in pale brown shining scales, unalterable in the air, very sparingly soluble in cold water, much more soluble in boiling water, soluble also in ether, and freely so in boiling alcohol. It has neither acid nor alkaline properties. Nitric acid dissolves it with effervescence, producing a rich deep red colour. Its taste, at first not very decided in consequence of its sparing solubility, becomes at length very bitter and permanent; and its alcoholic solution is intensely bitter. Should it be found to be the purgative principle of the plant, it would be entitled to the name of *podophyllin*. It may be obtained by boiling the root with quicklime in water, straining the decoction, precipitating the lime with sulphate of zinc, evaporating the clear solution to the consistence of an extract, treating this with cold alcohol of 0.817, filtering and evaporating the alcoholic solution, and treating the residue with boiling distilled water, which deposits the bitter principle on cooling. (*Journ. of the Phil. Col. of Pharm.* iii. 273.)

Medical Properties and Uses. *Podophyllum* is an active and certain cathartic, producing copious liquid discharges without much griping or other unpleasant effect. In some cases it has given rise to nausea and even vomiting, but the same result is occasionally experienced from every active cathartic. Its operation resembles that of jalap; but is rather slower, and is thought by some to be more drastic. It is applicable to most inflammatory affections which require brisk purging; and is much employed in vari-

ous parts of the country, especially combined with calomel, in bilious fevers and hepatic congestions. It is also frequently used in connexion with the bitartrate of potassa in dropsical, rheumatic, and serofulous complaints.

The dose of the powdered root is about twenty grains. An extract is prepared from it possessing all its virtues in a smaller bulk. (See *Extractum Podophylli*.) In minute doses frequently repeated, podophyllum is said to diminish the frequency of the pulse, and to relieve cough; and for these effects is sometimes used in hæmoptysis, catarrh, and other pulmonary affections.

W.

POLYGALA RUBELLA. U. S. Secondary.

Bitter Polygala.

“The root and herb of Polygala rubella.” U. S.

POLYGALA. See SENEGA.

Polygala rubella. Willd. *Sp. Plant.* iii. 875; Bigelow, *Am. Med. Bot.* iii. 129.—*P. polygama*. Walter, *Flor. Car.* 179; Pursh, *Flor. Am. Sept.* 465. This species of Polygala is an indigenous, perennial plant, with a branching, somewhat fusiform root, which sends up annually numerous simple, smooth, and angular stems, from four to eight inches in height. The leaves are scattered, sessile, obovate or linear lanceolate, attenuated towards the base, obtuse, and mucronate. The flowers are purple, and in elongated terminal racemes. From the base of the stem proceed other racemes, which lie upon the ground, or are partially buried under it, and bear incomplete but fertile flowers, the calyx of which is without wings.

This plant is found in many parts of the United States, preferring a dry sandy or gravelly soil, and flowering in June and July. The whole plant is officinal. It has a strong and permanent bitter taste, which it yields to water and alcohol.

Medical Properties and Uses. In small doses it is tonic, in larger laxative and diaphoretic. The infusion of the dried plant has been usually employed to impart tone to the digestive organs. (Bigelow.) It appears to be closely analogous in medical virtues to the *Polygala amara* of Europe, which is used for a similar purpose.

W.

POLYGONUM BISTORTA. Radix. Dub.

Bistort Root.

Bistorté, *Fr.*; Natter-Wurzel, *Germ.*; Bistorta, *Ital.*, *Span.*

POLYGONUM. *Sex. Syst.* Octandria Trigynia.—*Nat. Ord.* Polygonaceæ.

Gen. Ch. Corolla five-parted, calycine. Seed one, angular. Willd.

Besides the bistort, some other plants belonging to this genus, have been used as medicines. Among these are the *P. aviculare* or knot-grass, a mild astringent formerly employed as a vulnerary and styptic; the *P. Persicaria* (*Persicaria mitis*), of a feebly astringent saline taste, and at one time considered antiseptic; and the *P. Hydropiper* or water-pepper (*Persicaria urens*), the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic. The water-pepper or smart-weed of this country—*P. punctatum* (Elliott), *P. Hydropiperoides* (Michaux)—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as

a detergent in chronic ulcers, and internally in gravel. Dr. Eberle very strongly recommended it in amenorrhœa, in which complaint he found no other remedy equally effectual. He gave a fluidrachm of the saturated tincture of the plant, or from four to six grains of the extract, three or four times a day. He found it to produce a warmth and peculiar tingling sensation throughout the system, with slight aching pains in the hips and loins, and a sense of weight and tension within the pelvis. (*Eberle's Mat. Med.* 4th ed. vol. i. p. 441.) The *P. Fagopyrum* is the common buckwheat.

Polygonum Bistorta. Willd. *Sp. Plant.* ii. 441; Woodv. *Med. Bot.* p. 668. t. 232. This plant has a perennial root, and an annual herbaceous stem, which is simple, erect, jointed, and rises one or two feet in height. The lower leaves are cordate lanceolate, and supported on long winged foot-stalks; the upper are ovate, almost sessile, amplexicaule, and sheathing. The flowers are of a pale rose colour, and form a close terminal spike. The plant is a native of Europe and the North of Asia.

The root, which is the officinal portion, is cylindrical, somewhat flattened, about as thick as the little finger, marked with annular or transverse wrinkles, furnished with numerous fibres, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. When dried, it is solid, brittle, of a deep brown colour externally, reddish within, destitute of smell, and possessed of a rough, astringent taste. It contains much tannin, some gallic acid and gum, and a large proportion of starch.

Medical Properties. Bistort resembles the other vegetable astringents, such as galls, kino, &c., in medical properties, and is applicable to the same complaints; but in this country it is seldom or never used. It may be employed in the form of decoction or of powder. The dose of the latter is twenty or thirty grains, three or four times a day. W.

PORRUM. *Lond.*

Leek Root.

“*Allium Porrum. Bulbus.*” *Lond.*

Poireau, *Fr.*; Gemeiner Lauch, *Germ.*; Porro, *Ital.*; Puerro, *Span.*

ALLIUM. See ALLIUM.

Allium Porrum. Willd. *Sp. Plant.* ii. 64. “Stem flat-leaved, umbelliferous. Stamens tricuspidate. Root tunicated.”

The leek is a biennial bulbous plant, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive pungent odour, and an acrid taste, dependent on an essential oil, which is in great measure dissipated by decoction, and may be obtained separate by distillation. The bulb, which is the officinal portion, consists of concentric layers, like the onion, which it resembles in medical properties, though somewhat milder. It is gently stimulant, with a peculiar direction to the kidneys. The expressed juice may be given in the dose of a fluidrachm, mixed with syrup. This species of *Allium* is not used medicinally in the United States. W.

POTASSIUM.

Potassiumi.

Potassium, *Fr.*; Potassium, Kalimetall, *Germ.*; Pottassio, *Ital.*; Potasio, *Span.*

Potassium is a peculiar metal, and the radical of a number of important medicinal preparations. It was discovered in 1807 by Sir H. Davy,

who obtained it by decomposing hydrate of potassa by galvanic electricity. It was afterwards obtained in larger quantity by Gay-Lussac and Thenard, by bringing the fused alkali in contact with white hot iron, which attracted the oxygen and set free the metal. The best process is that of Brunner, as modified by Wöhler, which consists in decomposing potassa in the state of carbonate, mixed with charcoal. The mixture of carbonate and charcoal is obtained by heating cream of tartar to redness in a covered crucible.

Potassium is solid, softer and more ductile than wax, easily cut with a knife, and of a silver-white colour. A newly cut surface is brilliant; but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from every other substance. On account of this property it must be kept in liquids, such as naphtha, which are devoid of oxygen as a constituent. Its sp. gr. is 0.865, its melting point 136° , its equivalent number 39.15, and symbol K. When thrown upon water it swims, takes fire, and burns with a rose-coloured flame, combining with oxygen, and generating potassa which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic bodies, and with several of the metals. It combines in two proportions with oxygen, forming a protoxide (dry potassa) of a gray, and a teroxide of a yellowish-brown colour; the former containing one, and the latter three equivalents of oxygen to one of metal. It unites also with chlorine, and forms officinal compounds with iodine, bromine, sulphur, cyanogen, and ferrocyanogen, under the names of iodide, bromide, sulphuret, cyanuret, and ferrocyanuret of potassium. Its protoxide (dry potassa) is a very strong salifiable base, existing in nature always in combination, and forming with acids a numerous and important class of salts. Of these, the acetate, carbonate, bicarbonate, chlorate, citrate (in solution), hydrate (caustic potassa), nitrate, sulphate, sulphuretted sulphate, bisulphate, tartrate, and bitartrate are officinal, and will be described under their respective titles, to which, for their properties, the reader is referred.

B.

POTASSÆ BITARTRAS. U.S., Lond., Ed.

Bitartrate of Potassa.

Off. Syn. POTASSÆ BITARTRAS. TARTARI CRYSTALLI. *Dub.*

Cream of tartar, Crystals of tartar; Cremor tartari, *Lat.*; Tartrate acide de potasse, Crème de tartre, *Fr.*; Doppelt weinsaures Kali, Weinsteinrahm, *Germ.*; Cremore di tartaro, *Ital.*; Cremor de tartaro, *Span.*

During the fermentation of wines, especially those that are tart, a peculiar matter is deposited on the bottom and sides of the casks, forming a crystalline crust, called *crude tartar* or *argol*. That deposited from red wines is of a reddish colour, and is called in commerce *red tartar*; while that derived from white wines is of a dirty white colour, and is denominated *white tartar*. Both kinds consist of potassa, united with an excess of tartaric acid, forming bitartrate of potassa, rendered impure by tartrate of lime, more or less colouring matter, and the lees and other matters which are deposited during the clarification of the wine. The deposition of the tartar is thus explained. The bitartrate exists naturally in the juice of the grape, held in solution by saccharine matter. When the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is replaced by alcohol, which, not being competent

to dissolve the salt, allows it to precipitate as a crystalline crust. It is from this substance that cream of tartar is obtained by a process of purification.

The process is conducted on a large scale at Montpellier in France, and is founded upon the greater solubility of bitartrate of potassa in hot than in cold water. The tartar, previously pulverized, is boiled with water in copper boilers. The solution, when saturated, is transferred to earthen pans, where it deposits on cooling a crystalline layer, nearly free from colour. This is redissolved in boiling water; and the solution, having been mixed with four or five per cent. of pipe-clay, is evaporated to a pellicle. The clay precipitates with the colouring matter, and the clear solution, as it cools, deposits white crystals in crusts, which, upon being exposed to the air on linen for several days, acquire an increased degree of whiteness. These constitute the crystals of tartar, or cream of tartar of pharmacy. The salt, however, as met with in the shops, is generally, for greater convenience, in the form of powder; and it is to the substance in this form, that we are accustomed to apply the name of *cream of tartar*.

Properties. Bitartrate of potassa occurs in commerce in white crystalline crusts, or masses of aggregated crystals, and is received in that state from France by our wholesale druggists, who procure its pulverization for the use of the apothecaries. In crystals it is hard and gritty between the teeth, and dissolves slowly in the mouth; in powder it has a white colour. It is a permanent salt, of an acid not ungrateful taste, soluble in 184 parts of cold, and 18 of boiling water, but insoluble in alcohol. When exposed to a red heat it is decomposed, exhales a peculiar odour, gives rise to a solid pyrogenous acid, and the usual products of the destructive distillation of vegetable matter; and carbonate of potassa, mixed with charcoal, is left. Its solution is precipitated by solutions of baryta, strontia, and lime, which form insoluble tartrates, and by acetate of lead, forming tartrate of lead. If chloride of barium throws down a precipitate not entirely soluble in nitric acid, it indicates the presence of a sulphate; for the tartrate of baryta is soluble in this acid, but not the sulphate. With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral tartrate of potassa, and the tartrate of the base added. Several of them are important medicines, and will be described under their respective titles. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax or boric acid. These combinations are sometimes used in medicine, and will be described under borax. (See *Sodæ Boras*.)

The cream of tartar of commerce is not a pure bitartrate of potassa. It usually contains from two to five per cent. of tartrate of lime; and is sometimes adulterated with sand, clay, and similar substances. The fraud may be easily detected by the salt not being entirely soluble in boiling water, or by treating it with a hot solution of potassa, which will dissolve the cream of tartar, and leave the adulterating substances.

Composition. Cream of tartar consists of two eqs. of tartaric acid 132·96, one of potassa 47·15, and one of water 9=189·11. The water cannot be expelled without decomposing the salt, and is supposed to act the part of a base.

Medical Properties and Uses. Bitartrate of potassa is cathartic, diuretic, and refrigerant. In small doses it acts as a cooling aperient, in large ones as a hydragogue cathartic, producing copious watery stools; and from this latter property, as well as its tendency to excite the action of the kidneys, it is very much used in dropsical affections. It is frequently prescribed in

combination with sulphur or jalap. (See *Pulvis Jalapæ Compositus*.) Its solution in boiling water, sweetened with sugar and allowed to cool, forms an acid, not unpleasant, refrigerant drink, advantageously used in some febrile affections, and very much employed as a domestic remedy. The beverage called *imperial* is a drink of this kind, made by dissolving half an ounce of the salt in three pints of boiling water, and adding to the solution four ounces of white sugar, and half an ounce of fresh lemon peel. *Cream of tartar whey* is prepared by adding about two drachms of the bitartrate to a pint of milk. It may be given, diluted with water, in dropsical complaints. The dose of cream of tartar is a drachm or two as an aperient; and from half an ounce to an ounce as a hydragogue cathartic, mixed with molasses or suspended in water. As a diuretic in dropsical cases, it may be given in the dose of a drachm and a half or two drachms, several times a day.

In pharmacy, cream of tartar is employed to obtain the neutral tartrate of potassa (soluble tartar), tartrate of potassa and soda (Rochelle salt), tartrate of antimony and potassa (tartar emetic), and the tartrate of iron and potassa. Saturated by means of chalk, it forms tartrate of lime, which, decomposed by sulphuric acid, yields tartaric acid. Deflagrated with nitre, it is converted into a pure form of carbonate of potassa, called salt of tartar. (See *Potassæ Carbonas Purus*.) In the laboratory it is used to procure potassa in a pure state, and in making black and white flux. *Black flux* is prepared by deflagrating cream of tartar with half its weight of nitre; and *white flux*, by a similar process, with twice its weight of the latter salt.

POTASSÆ CARBONAS IMPURUS. U.S.

Impure Carbonate of Potassa.

“The impure carbonate of potassa known in commerce by the name of pearlash.” *U. S.*

Off. Syn. POTASSÆ CARBONAS IMPURA. *Lond.*; LIXIVUS CINIS. *Dub.*

Pearlash, Pearlashes, Impure potassa, Impure subcarbonate of potassa; Potasse du commerce, *Fr.*; Rohe Pottasche, *Germ.*; Potasch, *Dutch.*; Potaske, *Dan.*; Potaska, *Swed.*; Potassa del commercio, *Ital.*; Cenizas claveludas, *Span.*

The alkali potassa, using this term in its strict sense, is the protoxide of the metal potassium. (See *Potassium*.) It exists in various states of combination and purity. In its most impure state, it is the common *potash* of commerce. This, subjected to calcination, becomes somewhat purer, and is then called *pearlash*, the form of the alkali intended to be designated by the official name at the head of this article.

Natural State and Preparation. Potash and pearlash of commerce are procured from the ashes of wood, by lixiviation and the subsequent evaporation of the solution obtained. The alkali exists in the wood, principally in the state of acetate; and being of a fixed and incombustible nature, is left behind after the incineration. The wood is burnt on the ground, in a place

sheltered from the wind. The ashes consist of a soluble and insoluble portion. The soluble part is made up of carbonate of potassa, together with the sulphate, phosphate, and silicate of potassa, and the chlorides of potassium and sodium; and the insoluble portion, of carbonate and subphosphate of lime, alumina, silica, the oxides of iron and manganese, and a little carbonaceous matter that had escaped incineration. The ashes are lixiviated in barrels with the addition of a portion of lime, and the soluble substances above mentioned are taken up. The lixivium is then evaporated in iron kettles, which for several days are kept constantly full. The evaporation is continued until the mass has become of a black colour, and of the consistence of brown sugar. It is now subjected to as powerful a heat as can be raised by the best wood fire for a number of hours, by which it is fused. During the progress of the fusion, the combustible impurities are for the most part burnt out, and a gaseous matter is emitted, which agitates the more fluid part. When the fusion is complete, the liquid becomes quiescent, and looks like melted iron. It is now transferred, by means of large iron ladles, to iron pots, where it congeals in cakes. These are broken up and packed in tight barrels, and constitute the *potash* of commerce. (*Dr. G. A. Rogers*, in *Silliman's Journal*.)

If it be intended to make *pearlash*, the process is varied. In this case the black matter of the consistence of brown sugar, called *black salts* by our manufacturers, instead of being fused, is transferred from the kettles to a large oven-shaped furnace, so constructed that the flame may be made to play over the alkaline mass, which in the mean time is stirred by means of an iron rod. The ignition is in this way continued, until the combustible impurities are burnt out, and the mass, from being black, becomes of a dirty bluish-white colour. (*Rogers*.)

The ashes of plants amount generally to not more than a few parts in the hundred; and of these a portion only consists of potassa. The different parts of the same vegetable, and, for a stronger reason, different plants, furnish variable quantities of ashes. Ligneous plants furnish less than herbaceous, the trunk less than the branches, and the branches less than the leaves. The bark yields more ashes than the wood; and the leaves of trees which drop their leaves in winter, more than those of evergreens. The following table gives the quantity of potassa contained in the ashes of one thousand parts of different plants.

Pine,	-	-	0.45	Barley straw,	-	-	5.8

Commercial History. Pot and pearlash are made in those countries in which forests abound. Accordingly the alkali is extensively manufactured

in Canada and the United States, and constitutes a very important export of this country. It is prepared chiefly in the state of New York, which is supposed to furnish three-fourths of our export of this alkali. It is also produced in considerable quantities in the northern countries of Europe, especially in Russia, and on the shores of the Baltic. It is of different qualities as it occurs in commerce, being more or less pure; and is generally distinguished by the country or place of manufacture, as *American, Russian, Dantzic* potash, &c.

Properties. *Potash* is in the form of fused masses of a stony appearance and hardness, and caustic burning taste. Its colour is variegated, but reddish and dark brown are the predominant hues. When exposed to the air it absorbs moisture and deliquesces; and, if sufficiently long exposed, finally becomes liquid. *Pearlash* is of a white colour, with usually a tinge of blue. As it occurs in commerce, it is in tight casks, containing about three hundred and fifty pounds, in which it forms one entire hard concrete mass. In the shops it is found in coarse powder, intermingled with lumps as dug out of the casks, presenting an opaque granular appearance, like salt or Havana sugar. It is a deliquescent salt, and has a burning alkaline taste, but no smell. It is soluble in water, with the exception of impurities, which are more or less in quantity according to the quality of the alkali, of which three sorts exist in the market. One hundred grains of that of medium quality will neutralize about fifty-eight grains of sulphuric acid. It differs from potash principally in containing less combustible impurities, and in being less caustic and deliquescent. The colouring matter of both these forms of alkali is derived from carbonaceous impurities, and small portions of iron and manganese.

Composition. The basis of both pot and pearlash is carbonate of potassa; but this is associated with certain salts, and with insoluble impurities. Several varieties of potash found in commerce were analyzed by Vauquelin, whose results are contained in the following table. The quantity examined of each kind was 1152 parts.

KINDS OF POTASH.	Caustic Hydrate of Potassa.	Sulphate of Potassa.	Chloride of Potassium.	Insoluble Residue.	Carbonic Acid and Water.
American potash,	857	154	20	2	119
Russian potash,	772	65	5	56	254
Pearlash,	754	80	4	6	308
Potash of Trèves,	720	165	44	24	199
Dantzic potash,	603	152	14	79	304
Potash of Vosges,	444	148	510	34	16

By the above table it is perceived that the American potash contains 74 per cent. of pure hydrated alkali, and the Russian 67 per cent. Pearlash, it is seen, is more rich in carbonic acid than potash; and this result of analysis corresponds with the qualities of the two substances as prepared in the United States; potash being known to be far more caustic than pearlash. The greater causticity of the American potash compared with most of the varieties of Europe, probably depends upon the use of lime with us, which is not mentioned as being employed in the preparation of the commercial alkali in the best European works. The usual saline impurities are shown by the table to be sulphate of potassa and chloride of potassium. The insoluble residue consists principally of carbonaceous matter, which has escaped

incineration. Sometimes, however, insoluble matters are fraudulently added, such as brick-dust, sand, and other substances.

As the potash of commerce is valuable in the arts in proportion to the quantity of real alkali which it contains, it becomes important, in so variable a substance, to possess an easy method of ascertaining its quality in that respect. The process by which this is accomplished is called *alkalimetry*, and the instrument used an *alkalimeter*. The best mode of conducting the assay, which is applicable to the commercial forms of soda as well as those of potassa, is that proposed by Faraday, and described by Turner as follows. Take a cylindrical tube, sealed at one end, nine and a half inches long, and three quarters of an inch in diameter, and pour into it one thousand grains of water, marking with a file the point at which the water stands. Divide the space occupied by the water into one hundred equal parts, graduating from above downwards; and opposite to the numbers 23·44, 48·96, 54·63, and 65, severally, write the words soda, potassa, carbonate of soda, and carbonate of potassa. Then prepare a dilute sulphuric acid, having the specific gravity 1·127, which may be formed by adding to the strong acid, about four times its volume of distilled water. An acid of this strength, if added to the tube so as to reach to any one of the heights denoted by the above numbers, will be just sufficient to neutralize one hundred grains of the alkali written opposite to it. Suppose, for example, that the dilute acid be added until it stands opposite to the word carbonate of potassa, we shall then have the exact quantity necessary to neutralize one hundred grains of that carbonate; and if we add pure water, until the liquid reaches to 0, or the beginning of the scale, it is evident that the acid has been brought to the bulk of a hundred measures, each of which would be competent to neutralize one grain of the carbonate in question. All that is now necessary in order to ascertain the quality of any commercial sample of this carbonate, is to dissolve one hundred grains of it in warm water, filter the solution to remove insoluble impurities, and add by degrees the dilute acid from the tube until the solution is exactly neutralized, as shown by litmus paper. The number of divisions of acid, expended in attaining this point, may be read off from the tube; and for each division one grain of real carbonate is indicated.

Pharmaceutical Uses. Pearlash is never used as a medicine in regular practice, being considered as too impure; but it is employed pharmaceutically in several processes. The Dublin College uses it for depriving rectified spirit of water, in the process for strengthening it, and it is directed to be purified, in all the Pharmacopœias, to form the carbonate of potassa. This remark is applicable to the Edinburgh Pharmacopœia; for although pearlash has been expunged from the official list of that work, yet it is mentioned under the name of “potashes of commerce,” as the proper material for making the carbonate.

Off. Prep. Potassæ Carbonas, U. S., Lond., Dub.

B.

POTASSÆ CHLORAS. *Lond.*

Chlorate of Potassa.

Oxymuriate of potassa, Hyperoxymuriate of potassa; Chlorate de potasse, *Fr.*; Chlorsaures Kali, *Germ.*

Chlorate of potassa may be prepared by passing an excess of chlorine through a solution of either caustic hydrate, or carbonate of potassa. At first two eqs. of chlorine react with two eqs. of potassa, so as to form one

eq. of chloride of potassium, and one eq. of hypochlorite of potassa ($2\text{Cl} + 2\text{KO} = \text{KCl} + \text{KO}, \text{ClO}$). Afterwards, by the further action of the chlorine, more chloride of potassium is formed, and the oxygen separated from the potassa converts the hypochlorous acid into the chloric, and consequently the hypochlorite into chlorate of potassa. Thus, $4\text{Cl} + 4\text{KO} + \text{KO}, \text{ClO} = 4\text{KCl} + \text{KO}, \text{ClO}_5$. The chlorate, being but sparingly soluble in water, is separated from the chloride of potassium by priority of crystallization. When carbonate of potassa is used, the carbonic acid is first transferred from a part of the alkali to the remainder, and finally evolved.

Graham has devised an improved process for obtaining this salt. It consists in mixing the carbonate of potassa with an equivalent quantity of hydrate of lime, before submitting it to the action of chlorine. The gas is absorbed with avidity, and the mass becomes hot, while water is given off abundantly. The lime converts the carbonate into caustic potassa, and the reaction then takes place between six eqs. of potassa and six of chlorine, with the result of forming five eqs. of chloride of potassium, and one of chlorate of potassa. ($6\text{KO} + 6\text{Cl} = 5\text{KCl} + \text{KO}, \text{ClO}_5$.) The products are, therefore, carbonate of lime, chloride of potassium, and chlorate of potassa. The chloride and chlorate are separated from the carbonate by solution in hot water, and the chlorate from the chloride by priority of crystallization as before.

Properties. Chlorate of potassa is a white anhydrous salt, of a cooling and slightly acerb taste. It crystallizes in rhomboidal plates of a pearly lustre. It is soluble in sixteen parts of water at 60° and in two and a half parts of boiling water. When thrown on burning coals, it augments their combustion remarkably. This property is due to the presence of oxygen, which may be evolved from the salt in the proportion of nearly 39 per cent., by heating it a little above its point of fusion. The residue is chloride of potassium.

Chlorate of potassa is characterized by giving out oxygen upon fusion, and leaving a residue of chloride of potassium; by becoming first yellow and then red, by admixture with a little sulphuric acid, and by the action of that acid evolving chlorous acid gas (quadroxide of chlorine), known by its yellow colour, and explosive property when heated; by its bleaching power when mixed first with muriatic acid and then with water; and by its property of exploding violently when triturated with a small portion of sulphur or phosphorus. Its usual impurity is chloride of potassium, which may be detected by a precipitate of chloride of silver being produced on the addition of nitrate of silver. It consists of one equiv. of chloric acid 75.42 , and one of potassa $47.15 = 122.57$.

Medical Properties and Uses. Chlorate of potassa is ranked as a refrigerant and diuretic. From experiments made by Dr. O'Shaughnessy and others, it gives a bright scarlet colour to the venous blood, and passes undecomposed into the urine. The first trials made with it as a medicine were founded upon the supposition that it would prove an oxygenating remedy; and hence it was employed in scurvy which was supposed to depend upon a deficiency of oxygen in the system, and in syphilis and liver complaint as a substitute for mercury, which mineral was held by some to act in these affections by imparting oxygen. In scurvy it appears to have acted beneficially, but not on the principle which induced its trial; as it would seem not to be decomposed in the system. More recently it has been employed by Dr. Stevens and others as a remedy for certain fevers, and for malignant cholera, to supply a supposed deficiency of saline matter in the blood. For an account of its physiological effects and the trials which have been made

with it as a medicine, the reader is referred to *Pereira's Elements of Materia Medica*, 2d ed. 1842. The dose is from ten to thirty grains.

Chlorate of potassa is used to obtain pure oxygen; to make matches which take fire by friction, or when dipped in sulphuric acid; and to prepare priming for cannon and fire-arms. It forms a stronger gunpowder than nitre, but too dangerous to be employed, on account of the facility with which it explodes. B.

POTASSÆ NITRAS. U.S., Lond., Ed., Dub.

Nitrate of Potassa.

Nitre, Saltpetre; Nitrum, *Lat.*; Nitrate de potasse, Azotate de potasse, Nitre, Salpêtre, *Fr.*; Salpetersaures Kali, Salpeter, *Germ.*; Salpeter, *Dutch., Dan., Swed.*; Nitro, *Ital., Span., Port.*

Nitre or saltpetre is both a natural and artificial production. It is found ready formed in many countries, existing in the soil on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in Egypt, and in Peru, but the country in which it is most abundantly produced is India, from which the principal part is furnished for the demands of commerce. In the United States it is found in Georgia, Tennessee, Virginia, Maryland, Ohio, and Kentucky. It exists, in these States, for the most part in caverns situated in limestone rock, called saltpetre caves, and is associated with nitrate of lime. The earths contained in them are lixiviated, and yield, according to their richness, from one to ten pounds of crude nitre to the bushel. These caves are particularly numerous in Kentucky, and furnished a large portion of the nitre consumed in the United States during the late war. It exists also in the vegetable kingdom, having been found in borage, tobacco, bugloss, parietaria, hemlock, and the sun-flower. The artificial sources of nitre are certain mixtures of animal and vegetable substances with wood-ashes and calcareous matter, called nitre beds; and certain materials, impregnated with saltpetre, consisting principally of old plaster, derived from the demolition of old buildings.

Preparation from its Natural Sources. In India the saline earth, which on an average contains seven parts of nitre in a thousand, is placed in large mud filters lined with stiff clay, on which wood-ashes have been previously laid. Water is added, and the solution filters through the wood-ashes, with the effect of converting any nitrate of lime present, which amounts to nearly one per cent., into nitrate of potassa. The solution obtained is evaporated in earthen pots, filtered, and set aside to crystallize. The impure nitre thus obtained, contains from 45 to 70 per cent. of the pure salt. It is redissolved and crystallized by the native merchants, and thrown into commerce under the name of crude saltpetre.

Artificial Preparation. The plan of forming saltpetre in artificial nitre-beds is principally practised in Germany; while the method of obtaining it from old plaster rubbish is followed in France. *Artificial nitre-beds* are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed under sheds, to shelter them from the rain; while the sides are left open to permit the free access of air. The matter is disposed in little ranges or heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, by uniting

with the potassa existing in the vegetable remains, forms nitre. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be lixiviated. The lixiviation is performed with boiling water, which is repeatedly thrown upon fresh portions of the mass, until the solution obtained is sufficiently strong. The lixivium is of a brown colour, and contains chiefly the nitrate of potassa, but at the same time more or less of the nitrates of lime and magnesia, and of common salt. The earthy nitrates are then decomposed by a solution of wood-ashes, which, by furnishing potassa, converts them into nitre, and precipitates the earths. The solution being further evaporated, the common salt rises to the surface as a scum, and is removed. The solution is then allowed to cool, and the nitre crystallizes in dirty white crystals, called crude nitre.

When obtained from old plaster rubbish, the material is reduced to powder and lixiviated, in order to exhaust it of every thing soluble. The solution is found to contain the nitrates of potassa and lime, and common salt, and is treated with wood-ashes, which convert the nitrate of lime into nitrate of potassa, with precipitation of the earth as a carbonate. The liquor is separated from the precipitate and concentrated by heat; and the common salt as it rises to the surface is skimmed off. When the solution is so strong as to mark 45° of Baumé's areometer, it is allowed to cool and crystallize; and the crystals form the crude nitre of this process. The salt obtained in this way generally contains from 85 to 88 per cent. of pure nitre; the remainder being made up of chloride of sodium, and certain deliquescent salts. The details of this process as practised in Paris, are given with minuteness by Thenard.

Purification. Nitrate of potassa, as first obtained, either from natural or artificial sources, is called in commerce *crude saltpetre*, and requires to be purified or refined before it can be used in medicine, or in most of the arts. The process, which is founded principally on the fact that nitre is more soluble than common salt in hot water, is conducted in the following manner in France. Thirty parts of the saltpetre are boiled with six parts of water, and the portion which remains undissolved, or is deposited, consisting of common salt, is carefully removed. As the ebullition proceeds, a little water is added from time to time, to hold the nitre in solution. When common salt ceases to be separated, the solution is clarified with glue, and more water is added at intervals, until the whole amounts, including that previously added, to ten parts. The clear solution is now transferred to large, shallow copper coolers, where it is agitated with wooden instruments, to hasten the cooling, and to cause the nitre to crystallize in small grains. The purification is completed by washing the salt with water, or a saturated solution of nitre, in a kind of wooden hopper, with holes in the bottom stopped with pegs. The liquid employed is allowed to remain in contact with the nitre for several hours, at the end of which time it is permitted to drain off by taking out the pegs. The salt being now dried, its purification is completed.

In Sweden, the process of purification is conducted in a different manner. The solution of the crude nitre is boiled, until a saline crust (common salt) forms on its surface, and until it is so far concentrated that a small portion of it crystallizes upon cooling. The crust being removed, the solution is filtered, and diluted with 1-48th of water, with a view to retain in solution the common salt, which, being somewhat less soluble in cold than in boiling water, would otherwise be in part precipitated on refrigeration. The solution is now allowed to cool, and, at the moment crystals begin to form,

is stirred constantly to cause the salt to crystallize in small grains. The granular salt is then washed after the French method, as above described, dried, and being fused, is cast in sheet iron moulds, so as to form masses, each weighing from ten to twenty pounds. The preparation of nitre in this manner by fusion is, according to Berzelius, attended with several advantages; such as its occupying less space, its losing nothing by waste in transportation, and in its presenting in this state an obvious index of its quality. This index is the character of its fracture. When the salt is perfectly pure, this is radiated, the radii being generally large. The presence of 1-80th of common salt renders the radii smaller; and of 1-40th or a larger quantity, produces a zone in the substance of the mass, devoid of the radiated structure, or causes this structure to disappear entirely. On the other hand, the process by fusion has the disadvantage of converting the salt in part into hyponitrite when heated too high, and of rendering it difficult to pulverize.

Commercial History. Nitre is received in this country from Calcutta in the state of crude saltpetre, packed in grass cloth bags, containing from one hundred and fifty to one hundred and seventy-five pounds. The greater portion of it arrives at Boston. Its quality varies considerably. That which comes in dirty yellow crystals is called *crude saltpetre*; while the finer lots, in small, comparatively clear crystals, approaching to white, are called *East India refined*. Very little crude saltpetre is at present prepared in the United States, on account of the low price of that from India. The *refined saltpetre* is almost exclusively prepared by our own chemists; and a considerable portion of it is exported.

As connected with the subject of saltpetre, it may be proper in this place to notice what is incorrectly called *South American saltpetre*, considerable quantities of which have been received within a few years from Peru. It is the *nitrate of soda*, and comes in bags containing about two hundred and seventy pounds of the salt in the crude state. This nitrate is coming into use with our manufacturing chemists, and is better suited than nitre for preparing nitric and sulphuric acids, on account of the greater proportional quantity of acid which it contains. It is, however, not applicable to the purpose of making gunpowder, from its tendency to absorb moisture.

Properties. Nitre is a white salt, possessing a sharp, cooling, and slightly bitterish taste, and generally crystallized in long, striated, semitransparent, six-sided prisms, with dihedral summits. It dissolves in four or five times its weight of cold, and in about two-fifths of its weight of boiling water. It is sparingly soluble in rectified spirit, but insoluble in absolute alcohol. It undergoes no alteration in the air, unless this be very moist. It contains no water of crystallization; but is apt to hold a portion of liquid, mechanically lodged within the substance of the crystals. This is particularly the case with the *large* crystals, and, according to Berzelius, is a source of impurity; as the liquid in question is a portion of the mother-waters in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be agitated, so as to cause it to shoot into *small* crystals. When exposed to heat, nitre fuses at about 662°. The fused mass, when cast in moulds, or formed into little circular cakes, constitutes that form of nitre kept in the shops under the name of *crystal mineral* or *sal prunelle*.* If the heat be increased, the salt is decomposed,

* *Sal prunelle*, as directed to be made in the French Codex, is a mixture of nitrate and sulphate of potassa. It is prepared by fusing nitre in a Hessian crucible, adding 1-128th part of sulphur, and pouring out the product on a smooth marble slab, where it is allowed to congeal. The sulphur immediately takes fire, and by combining with oxy-

evolves pure oxygen, and is reduced to the state of hyponitrite, which, when rubbed to powder, emits orange-coloured fumes of nitrous acid and nitric oxide, on the addition of sulphuric acid. Upon a further continuance of the heat, the hyponitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less nitrogen. The residuum, after the gaseous matter has ceased to come over, is, according to Berzelius, a compound of potassa with nitric oxide; but, sometimes at least, it is the teroxide of potassium, as was observed about the same time by Mr. Phillips of London and Dr. Bridges of this city. On account of the large quantity of oxygen which it contains, nitre increases the combustion of many substances in a remarkable degree. When thrown on burning coals, it deflagrates with bright scintillations. Mixed with half its weight of sulphur, and two-thirds of its weight of pearlash, it forms a compound, powerfully detonating when struck with a hammer. Nitre may be readily recognised by its effect in increasing the combustion of live coals, when thrown upon them; and by evolving white or reddish vapours on the addition of sulphuric acid. When it has been fused, its radiated structure is a test of its purity. Its most usual impurity is common salt, which is seldom entirely absent, and which injures it for the manufacture of gunpowder. The presence of this salt is readily detected by nitrate of silver. If a sulphate be present it will cause a precipitate to be formed with chloride of barium. Lime is indicated by a precipitate being produced by oxalate of ammonia. The refined or purified saltpetre of commerce may be deemed the official nitre, and is sufficiently pure for medical use. Nevertheless, the Dublin College, with needless refinement, has given a formula for its purification. (See *Potassæ Nitras Purificatum*.)

Composition. Nitrate of potassa is composed of one equiv. of nitric acid 54·15, and one of potassa 47·15 = 101·3.

Medical Properties and Uses. Nitre is considered refrigerant, diuretic, and diaphoretic, and is much used in inflammatory diseases. It is known to be a powerful antiseptic. It generally promotes the secretion of urine and sweat, lessens the heat of the body and the frequency of the pulse, and has a tendency to keep the bowels in a soluble condition. It is very frequently prescribed with tartar emetic and calomel, forming a combination usually called the *nitrous powder*, which promotes most of the secretions, particularly those of the liver and skin, and which in many cases is advantageously employed in lessening and modifying febrile excitement. The formula usually preferred is eight or ten grains of nitre, the eighth of a grain of tartar emetic, and from a fourth to half of a grain of calomel, exhibited every two or three hours. Nitre is frequently given in active hemorrhages, particularly hæmoptysis, and is useful as an ingredient in gargles, in certain stages of inflammatory sorethroat. In the form of sal prunelle, it is rubbed with advantage on chapped lips. The dose is from ten to fifteen grains, dissolved in water or some mucilaginous fluid, and repeated every two or three hours. From one to three drachms may be exhibited in the course of the day. If given too freely, or for too long a period, it is apt to excite pains in the stomach. In an overdose, (half an ounce to an ounce or more,) sometimes taken by mistake for sulphate of soda, it causes heat and pain in the stomach, vomiting and purging of blood, great prostration, convulsions, and sometimes death. On dissection, the stomach and intestines are found in-

gen from the nitre, becomes sulphuric acid, which then unites with the potassa of this salt, and forms sulphate of potassa. This preparation is said to be called sal prunelle, because formerly it was the custom to give it a purple colour, resembling that of the plum.

flamed. The treatment in such cases consists in the speedy removal of the poison from the stomach, and in the administration of mucilaginous and demulcent drinks, laudanum to allay pain and irritation, and cordials to sustain the sinking powers of the system. No antidote is known.

Pharmaceutical Uses, &c. In pharmacy nitre is employed to form crocus of antimony, (see *London process for tartar emetic*,) and to procure nitric acid. It is also used in the formulas of the United States Pharmacopœia for obtaining sweet spirit of nitre and pure carbonate of potassa (*salt of tartar*). It enters into the composition of moxa, and is employed in preparing the sulphate of potassa with sulphur of the Edinburgh College. In the laboratory it is used as an oxidizing agent, and to yield oxygen at a red heat. One pound of it will furnish four hundred and fourteen pints of oxygen, sufficiently pure for experiments of illustration. In the arts, it is employed in the production of aquafortis, the manufacture of sulphuric acid, (see *Acidum Sulphuricum*,) and the fabrication of gunpowder. It is this last use which causes its principal consumption. In domestic economy, it is applied to the purpose of preserving meat, especially beef, to the fibre of which it communicates a red colour and considerable firmness.

POTASSÆ SULPHAS. *U. S., Lond., Ed., Dub.*

Sulphate of Potassa.

Vitriolated tartar; Tartarum vitriolatum, Arcanum duplicatum, Sal de duobus, *Lat.*; Sulfate de potasse, Potasse vitriolée, *Fr.*; Schwefelsaures Kali, Vitriolisirtir Weinstein, *Germ.*; Solfato di potassa, *Ital.*

This salt is placed among the preparations by the British Colleges, but in the *Materia Medica* list of the United States Pharmacopœia.

Preparation. Several chemical processes give rise to sulphate of potassa as a secondary product. Thus it is produced in the distillation of nitric acid from a mixture of nitre with sulphuric acid or with sulphate of iron; in the decomposition of sulphate of magnesia by carbonate of potassa, in forming carbonate of magnesia; and during the combustion of the mixture of nitre and sulphur in the manufacture of sulphuric acid. (See *Acidum Nitricum*, and *Acidum Sulphuricum*.) When nitric acid is obtained by calcining a mixture of nitre and sulphate of iron, the residue consists of sesquioxide of iron and sulphate of potassa, the latter of which, being alone soluble, is separated by means of water, and crystallized from its solution. The residue of the combustion of sulphur and nitre, in making sulphuric acid, is an impure sulphate of potassa mixed with sulphur, and is not purified for use in medicine, but sold to the alum makers; sulphate of potassa being one of the saline ingredients of that double salt.

The British Colleges agree in obtaining sulphate of potassa from the salt which remains after the distillation of nitric acid. This salt is a supersulphate of potassa, and must be so prepared as to bring it to the neutral state. The London College brings it to this state by igniting it in a crucible; the Dublin College, by saturating the excess of acid with carbonate of potassa; and the Edinburgh College, by removing the excess by the addition of white marble, which converts it into an insoluble sulphate of lime. The directions of the London College are as follows. "Take of the salt which remains

after the distillation of nitric acid two pounds, boiling water two gallons. Ignite the salt in a crucible until the excess of sulphuric acid is entirely expelled; then boil it in the two gallons of water until a pellicle forms, and the liquor being strained, set it aside that crystals may form. Pour off the liquor from the crystals and dry them." This is a new process of the London Pharmacopœia, which is stated by Mr. Phillips to be more economical than the former one, in which the excess of acid was saturated by carbonate of potassa.

Properties. Sulphate of potassa is a white, anhydrous salt, in the form of small, aggregated, transparent, very hard crystals, permanent in the air, having the shape usually of short six-sided prisms, terminated by six-sided pyramids, and possessing a nauseous, somewhat bitter taste. It is slowly soluble in about sixteen times its weight of cold, and five times its weight of boiling water; but is insoluble in alcohol. When thrown upon burning coals it decrepitates, and exposed to a strong red heat it undergoes fusion. It exists naturally in ligneous vegetables, and hence is present in their ashes. Added to a solution of sulphate of alumina, it generates alum, recognised by the octohedral shape of its crystals. It is decomposed by tartaric acid, which forms bitartrate of potassa, and by the soluble salts of baryta, strontia, lime, silver, and lead, forming insoluble or sparingly soluble sulphates. This salt is not subject to adulteration. It consists of one equiv. of sulphuric acid 40.1, and one of potassa 47.15 = 87.25.

Medical Properties and Uses. Sulphate of potassa is a mild purgative, operating without heat, pain, or other symptoms of irritation. In small doses, from a scruple to half a drachm, it operates as an aperient, and is useful in removing obstructions; in larger doses, of four or five drachms, it acts slowly as a purge. Combined with rhubarb, in the proportion of about a drachm of the salt to ten grains of the root, Dr. Fordyce found it an excellent alternative cathartic in the visceral obstructions of children, characterized by a tumid abdomen, and defective digestion and nutrition; and we can bear testimony to its efficacy in these cases from our own experience. Dr. A. T. Thomson states that this salt, in combination either with rhubarb or aloes, has proved in his hands "more useful than any of the other saline purgatives, in jaundice and dyspeptic affections." It enters into the composition of Dover's powder, in which it assists in pulverizing the other ingredients when triturated with them, in consequence of the hardness of its crystals. In the arts it is employed in making alum, and by the refiners of saltpetre for converting nitrate of lime into nitrate of potassa.

POTASSII FERROCYANURETUM. U.S.

Ferrocyanuret of Potassium.

Off. Syn. POTASSII FERROCYANIDUM. *Lond., Ed.*

Ferrocyanide of potassium, Ferrocyanate of potassa, Ferroprussiate of potassa, Prussiate of potassa; Proto-cyanure jaune de fer et de potassium, *Fr.*; Cyaneisenkalium, *Germ.*

This is the yellow double cyanuret of potassium and iron, the salt from which the cyanuret of potassium is obtained by calcination at a low red heat. (See *Potassii Cyanuretum.*)

Preparation. This salt is prepared on a large scale by calcining animal matters, such as dried blood, hoofs, horns, and other substances rich in

nitrogen, with the pearlash of commerce, in an egg-shaped iron pot, dissolving the calcined mass, after cooling, in water, and evaporating the solution so as to crystallize. The requisite iron for forming the salt is derived from the pots and stirrers used in the process. Occasionally iron filings are added.

Properties. Ferrocyanuret of potassium is in large, beautiful, transparent, permanent, four-sided, tabular crystals, of a lemon-yellow colour, devoid of odour, but possessing a sweetish, yet somewhat bitter, saline taste. It dissolves in between three and four times its weight of cold water, and in about its own weight of boiling water, but is insoluble in alcohol. It acts but slightly, if at all, on turmeric paper. The alkaline reaction, when it occurs, is probably owing to the presence of a little free potassa retained by the water of crystallization. (*R. Phillips.*) When heated to 140° it loses its water of crystallization, amounting to 12.6 per cent., and becomes white. When ignited, the fixed residue amounts to 18.7 per cent. of sesquioxide of iron, resulting from the oxidizement of the iron of the salt. It is characterized by striking a deep blue colour with the sesquisalts of iron, a deep brown one with the salts of copper, and a white one with those of zinc; the several precipitates formed being cyanurets of the respective metals. Ferrocyanuret of potassium consists of two eqs. of cyanuret of potassium 131.08, one of cyanuret of iron 54.39, and three of water $27 = 212.47$. The water present is just sufficient to convert the iron and potassium into protoxides, and the cyanogen into hydrocyanic acid. Apart from the water present, it is generally considered to consist of a compound radical, called *ferrocyanogen*, formed of three eqs. of cyanogen and one of iron (tercyanuret of iron), united with two eqs. of potassium. Hence its official name. This salt is remarkably pure as it occurs in commerce.

Medical Properties, &c. From experiments undertaken chiefly by the German physicians, to determine the physiological effects of this salt, it would appear to have but little activity. Callies, as quoted by Pereira, found the commercial salt slightly poisonous, but the pure salt unproductive of harm in the dose of several ounces. It should be borne in mind that it is the commercial salt which is used medicinally. Westrumb and Hering proved that it passed with rapidity into the blood and urine.

Notwithstanding the above statements, Dr. Burleigh Smart, of Kennebec, Maine, has attributed to this salt valuable medicinal powers. (*Am. Journ. of Med. Sci.* xv. 362.) Its primary effect, according to him, is that of a sedative, diminishing the fulness and frequency of the pulse, and allaying pain and irritation. It also acts, under favourable circumstances, as a diaphoretic and astringent. Dr. Smart used it with success in a case of chronic bronchitis in a child, with the effect, in a few days, of diminishing the frequency of the pulse, and of lessening the sweating, cough, and dyspnoea. It sometimes acts as a diaphoretic, but only in cases attended with excessive vascular action and increased heat of skin. As an astringent its power is most conspicuous in the colliquative sweats of chronic bronchitis and phthisis. The same power was evinced in several cases of leucorrhœa cured by its use. It sometimes produces pyalism, unattended, however, by swelling of the salivary glands or fetor of the breath. Its properties as an anodyne and sedative render it applicable to cases of neuralgic pains and whooping cough, in which diseases, especially the latter, Dr. Smart found it useful. When given in an over-dose he states that it occasions vertigo, coldness, and numbness, with a sense of gastric sinking.

The form of administration which Dr. Smart prefers is that of solution, in the proportion of two drachms to the fluidounce of water. Of this the

dose for an adult is from 30 to 45 drops, equivalent to from 10 to 15 grains of the salt, repeated every four or six hours. Should the results of Dr. Smart be confirmed, the ferrocyanuret of potassium will form an important acquisition to the *Materia Medica*.

This salt is manufactured on a large scale, chiefly for the use of the dyers and calico-printers. In pharmacy it is employed to prepare hydrocyanic acid, Prussian blue, and cyanuret of potassium.

PRINOS. *U. S.*, Secondary.

Black Alder.

“The bark of *Prinos verticillatus*.” *U. S.*

PRINOS. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Aquifoliaceæ.

Gen. Ch. Calyx small, six-cleft. Corolla monopetalous, subrotate, six-parted. Berry six-seeded; seeds nuciform. *Nuttall*.

Prinos verticillatus. Willd. *Sp. Plant.* ii. 225; Bigelow, *Am. Med. Bot.* iii. 141; Barton, *Med. Bot.* i. 203. The black alder is an indigenous shrub, with a stem six or eight feet high, furnished with alternate, spreading branches, and covered with a bluish-gray bark. The leaves, which stand alternately or irregularly on short petioles, are oval, pointed, tapering at the base, acutely serrate, of a dark green colour, smooth on their upper surface, but downy on the veins beneath. The flowers are small, white, nearly sessile, and grow three or four together at the axils of the leaves. They are often diœcious. The calyx is persistent; the segments of the corolla obtuse; the stamens usually six in number, and furnished with oblong anthers; the germ large, green, roundish, and surmounted by a short style, terminating in an obtuse stigma. The fruit when ripe consists of glossy, scarlet, roundish berries, about the size of a pea, containing six cells and six seeds. Several of these berries are clustered together so as to form little bunches at irregular intervals on the stem. In the latter part of autumn, after the leaves have fallen, they still remain attached to the stem, and render the shrub a striking object in the midst of the general nakedness of vegetation. Hence the plant has received the name of *winter-berry*, by which it is frequently designated.

It grows in all parts of the United States, from Canada to Florida, frequenting low wet places, such as swamps, and the borders of ponds, ditches, and streams. Its flowers appear in June. The berries, which have a bitter, sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes with the bark, which is the officinal portion.

The dried bark is in slender pieces, more or less rolled, brittle, greenish-white internally, and covered with a smooth epidermis which is easily separable, and of a whitish-ash colour, alternating or mingled with brown. It has no smell. The taste is bitter and slightly astringent. Boiling water extracts the virtues of the bark.

Medical Properties and Uses. Black alder is usually considered tonic and astringent; and is among the remedies which have been proposed as substitutes for Peruvian bark, with which, however, it has very little analogy. It has been recommended in intermittent fever, diarrhœa, and other diseases connected with a debilitated state of the system, especially gangrene and mortification. It is a popular remedy in gangrenous or flabby and ill-conditioned ulcers, and in chronic cutaneous eruptions, in which it is given

internally, at the same time that it is applied locally in the form of a wash or poultice.

It may be used in substance or decoction. The dose of the powder is from thirty grains to a drachm, to be repeated several times a day. The decoction, which is usually preferred both for internal and external use, may be prepared by boiling two ounces of the bark with three pints of water to a quart, and given in the dose of two or three fluidounces. A saturated tincture, as well of the berries as of the bark, is sometimes employed.

PRUNUS. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Amygdalæ.

Gen. Ch. *Calyx* inferior, bell-shaped, deciduous, with five obtuse, concave segments. *Petals* five, roundish, concave, spreading, larger than the segments of the calyx, into the rim of which they are inserted. *Filaments* awl-shaped, nearly as long as the corolla, from the rim of the calyx within the petals. *Anthers* short, of two round lobes. *Ovary* superior, roundish. *Style* of the length of the stamens. *Stigma* orbicular, peltate. *Drupe* roundish or elliptical. *Nut* hard, somewhat compressed, of one cell, and two more or less distinct sutures with an intermediate furrow. *Leaves* rolled up when young. (*Lindley*.)

Prunus domestica. Willd. *Sp. Plant.* ii. 995; Woodv. *Med. Bot.* p. 520. t. 187. The cultivated prune or plum tree is so well known as to render a minute description unnecessary. We merely give the specific character. “*Peduncles* subsolitary; *leaves* lanceolate, ovate, convolute; *branches* not spiny.” The varieties of the tree produced by cultivation are very numerous. Nearly one hundred are to be found in the British gardens. Though at present growing wild in various parts of Europe, it is thought to have been brought originally from Asia Minor and Syria. It is the dried fruit only that is official.

The prunes brought to our market come chiefly from the South of France, the best from the port of Bordeaux. They are derived from the variety of the tree named *Juliana* by Linnæus. The fresh fruit, called *prune de Saint Julien* by the French, is of an oval shape, nearly an inch in length, and of a deep violet colour. It is prepared by drying in the sun after having been exposed to the heat of an oven. The finest prunes, used on the tables in France, are prepared from the larger kinds of plums, such as the *Saint Catharine* and *Reine-Claude* or *green-gage*. An inferior sort is brought from Germany.

Prunes have a feeble odour, and a sweet mucilaginous taste, which is generally also somewhat acid. They contain uncrystallizable sugar, malic acid, and mucilaginous matter. In Germany they obtain from this fruit a kind of brandy, which in some districts is largely consumed. Bonneberg, a German chemist, has succeeded in extracting crystallizable sugar, equal to that of the cane.

Medical Properties and Uses. Prunes are laxative and nutritious, and

stewed with water form an excellent diet in cases of costiveness, especially during convalescence from febrile and inflammatory diseases. As they impart their laxative property to water in which they are boiled, they serve as a pleasant and useful addition to purgative decoctions. Their pulp is also used in the preparation of laxative confections. Too largely taken in a debilitated state of the digestive organs, they are apt to occasion flatulence, and griping pain in the stomach and bowels.

W.

PRUNUS VIRGINIANA. U.S.

Wild-cherry Bark.

“The bark of *Cerasus serotina* (*De Candolle*), *Cerasus Virginiana* (*Michaux*).” *U. S.*

CERASUS. See LAURO-CERASUS.

This genus, which is recognised by most of the recent botanical writers, includes a large number of species formerly embraced in the genus *Prunus* of Linnæus.

Cerasus serotina. De Cand. *Prodrom.* ii. 540; Torrey and Gray, *Flora of N. America*, i. 410.—*Cerasus Virginiana*. Michaux, *N. Am. Sylv.* ii. 205. According to Torrey and Gray, the name *Prunus Virginiana*, which has frequently been applied to this species, was given by Linnæus to the *choke-cherry*—a small tree or shrub, growing in the Northern States, and bearing a dark red, globular, astringent fruit, about as large as that of the *wild-cherry*. This is described in the *Flora of N. America* of these authors, under the name of *Cerasus Virginiana*. The officinal species or *wild-cherry tree* is, according to Michaux, one of the largest productions of the American forest. Individuals were seen by that botanist on the banks of the Ohio from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But as usually met with in the Atlantic States, the tree is of much smaller dimensions. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk is regularly shaped, and covered with a rough blackish bark, which detaches itself semi-circularly in thick narrow plates, and by this peculiar character serves as a distinguishing mark of the tree, when the foliage is too high for inspection. The leaves are oval oblong, or lanceolate oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green, and supported alternately upon petioles, which are furnished with from two to four reddish glands. The flowers are small, white, and collected in long erect or spreading racemes. They appear in May, and are followed by globular drupes about the size of a pea, and when ripe of a shining blackish-purple colour.

This tree grows throughout the Union, flourishing most in those parts where the soil is fertile and the climate temperate, and abounding in the Middle Atlantic States, and in those which border on the Ohio. In the neighbourhood of Philadelphia, it affects open situations, growing solitarily in the fields and along the fences, and seldom aggregated in woods or groves. It is highly valued by the cabinet makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light red tint, which deepens with age. The fruit has a sweetish, astringent, bitter taste; and is much employed in some parts of the country to impart flavour to spirituous liquors. The inner bark is the part employed in medicine, and is obtained indiscri-

minately from all parts of the tree, though that of the roots is most active. It should be preferred recently dried, as it deteriorates by keeping.

Properties. Wild-cherry bark as kept in the shops is in pieces of various sizes, more or less curved laterally, usually destitute of epidermis, of a lively reddish cinnamon colour, brittle, and pulverizable, presenting a reddish-gray fracture, and affording a fawn-coloured powder. In the fresh state, or when boiled in water, it emits an odour resembling that of peach leaves. Its taste is agreeably bitter and aromatic, with the peculiar flavour of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion closely resembling Maderia wine in appearance. Its peculiar flavour as well as medical virtues are injured by boiling, in consequence partly of the volatilization of the principle upon which they depend, partly upon a chemical change effected by the heat. From an analysis by Dr. Stephen Procter, it appears to contain starch, resin, tannin, gallic acid, fatty matter, lignin, red colouring matter, salts of lime and potassa, and iron. He obtained also a volatile oil, associated with hydrocyanic acid, by distilling the same portion of water successively from several different portions of the bark. This oil was of a light straw colour, and very analogous in its properties to the volatile oil of bitter almonds. In the quantity of two drops it proved fatal to a cat in less than five minutes. (*Journ. of the Phil. Col. of Pharm.* vi. 8.) Mr. William Procter, of Philadelphia, has shown that, as in the case of bitter almonds, (see *Amygdala*,) the volatile oil and hydrocyanic acid do not exist ready formed in the bark, but are the result of the reaction of water upon amygdalin, which he ascertained to be one of its constituents. In order, however, that this change may take place, the agency of another principle, probably analogous to if not identical with *emulsin*, or the *synaptase* of Robiquet, is also essential; and, as this principle becomes inoperative at a boiling temperature, we can understand how decoction may interfere with the virtues of the bark. (*Am. Journ. of Pharm.* x. 197.) It is highly probable that wild-cherry bark contains also *phloridzin*, a bitter principle proved to exist in the bark of the apple, pear, cherry, and plum trees. (See *Phloridzin* in the Appendix.) In this case, an easy explanation is offered of the coexistence of tonic and sedative properties in this valuable medicine, the former depending on the phloridzin, the latter on the hydrocyanic acid.

Medical Properties and Uses. This bark is among the most valuable of our indigenous remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which a debilitated condition of the stomach, or of the system at large, is united with general or local irritation. When largely taken it is said to diminish the action of the heart, an effect ascribable to the hydrocyanic acid which it affords. Dr. Eberle states that copious draughts of the cold infusion, taken several times a day, and continued for nearly two weeks, had the effect of reducing his pulse from seventy-five to fifty strokes in the minute. The remedy is highly useful in the hectic fever of scrofula and consumption, in the treatment of which it has long been a favourite with many American practitioners. In the general debility which often succeeds inflammatory diseases, it has also been found advantageous, and it is well adapted to many cases of dyspepsia. It has been used successfully in intermittent fever, but in this complaint is much inferior to cinchona.

It may be used in powder or infusion. The dose of the powder is from thirty grains to a drachm. The infusion is properly directed by our national Pharmacopœia to be prepared with cold water. (See *Infusum Pruni Vir-*

ginianæ.) A syrup of wild-cherry bark is considerably used at present. It may be prepared by macerating four ounces of the powdered bark with twelve fluidounces of water for two days, putting the mixture into a displacement apparatus, returning the liquid which passes until it becomes clear, displacing with an additional quantity of water until twelve fluidounces of infusion are obtained, and then dissolving in this twenty-four ounces of sugar. (Procter, *Am. Journ. of Pharm.* xiv. 27.) The dose of this syrup would be about a fluidounce. But a serious objection to the syrup of wild-cherry bark is, that in order to give the requisite quantity of the medicine, so much sugar must be given at the same time as to endanger embarrassment of the digestive organs.

PYRETHRUM. U. S. Secondary, Lond., Ed., Dub.

Pellitory.

“The root of Anthemis Pyrethrum.” U. S. “Anthemis Pyrethrum. Radix.” Lond., Dub. “Root of Anacyclus Pyrethrum.” Ed.

Pyrethre, Fr.; Bertram Wurzel, Germ.; Piretro, Ital.; Pelitre, Span.

ANTHEMIS. See ANTHEMIS.

Anthemis Pyrethrum. Willd. *Sp. Plant.* iii. 2184; Woodv. *Med. Bot.* p. 50. t. 20.—*Anacyclus Pyrethrum.* De Cand. *Prodrom.* vi. 15. The root of this plant is perennial, and sends up numerous stems, which are usually trailing at the base, erect in their upper portion, eight or ten inches high, and terminated by one large flower. The leaves are doubly pinnate, with narrow nearly linear segments of a pale green colour. The florets of the disk are yellow; the rays are white on their upper surface, and reddish or purple beneath and at their edges.

The plant is a native of the Levant, Barbary, and the Mediterranean coast of Europe. The root is the part used under the name of pellitory, or *pellitory of Spain*. According to Hayne, the pellitory of the shops is derived from the *Anacyclus officinarum*, a plant cultivated in Thuringia for medical purposes. This remark, however, can apply only to Germany.

Properties. The dried root of the *A. Pyrethrum* is about the size of the little finger, cylindrical, straight or but slightly curved, wrinkled longitudinally, of an ash-brown colour externally, whitish within, hard and brittle, sometimes furnished with a few radicles. It is destitute of odour, though when fresh, of a disagreeable smell. Its taste is peculiar, slight at first, but afterwards acidulous, saline, and acrid, attended with a burning and tingling sensation over the whole mouth and throat, which continues for some time, and excites a copious flow of saliva. Its constituents, according to M. Gauthier, are a fixed oil, a yellow colouring matter, gum, inulin, lignin, with traces of volatile oil and of chloride of calcium. A more minute analysis by Koene gives, in 100 parts, 0.59 of a brown, very acrid substance, of a resinous appearance, and insoluble in caustic potassa; 1.60 of a dark brown, very acrid fixed oil, soluble in potassa; 0.35 of a yellow acrid oil, also soluble in potassa; traces of tannin; 9.40 parts of gum; inulin; 7.60 parts of sulphate and carbonate of potassa, chloride of potassium, phosphate and carbonate of lime, alumina, silica, &c.; and 19.80 of lignin, besides loss. (*Am. Journ. of Pharm.* viii. 175, from the *Journ. de Pharm.*)

Medical Properties and Uses. Pellitory is a powerful irritant, used almost exclusively as a sialagogue in certain forms of headache, rheumatic and neuralgic affections of the face, toothache, &c., or as a local stimulant

in palsy of the tongue or throat, and in relaxation of the uvula. For these purposes it may be chewed, or employed as a gargle in decoction or vinous tincture. It is seldom prescribed by medical practitioners in this country. The dose as a masticatory is from 30 grains to a drachm. W.

QUASSIA. U.S., Lond., Ed.

Quassia.

“The wood of *Quassia excelsa*.” U.S. “*Quassia excelsa*. *Lignum*.” Lond. “Wood chiefly of *Picræna excelsa* (Lindley), seldom of *Quassia amara*.” Ed.

Off. Syn. QUASSIA EXCELSA. *Lignum*. Dub.

Bois de quassie, Fr.; Quassienholtz, Germ.; Legno della quassia, Ital.; Leno de quassia, Span.

QUASSIA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Simarubaceæ.

Gen. Ch. *Calyx* five-leaved. *Petals* five. *Nectary* five-leaved. *Drupe*s five, distant, bivalve, one-seeded, inserted into a fleshy receptacle. Willd.

Of the species included by Linnæus in this genus, some, as the *Quassia amara*, are hermaphrodite; others, as the *Q. excelsa* and *Q. Simaruba*, are monœcious or polygamous. The latter have been associated together by De Candolle in a distinct genus, with the title *Simaruba*. This has been again divided by Lindley into *Simaruba* with monœcious, and *Picræna* with polygamous flowers. To the last-mentioned genus the proper quassia plant, the *Q. excelsa* of Linnæus, belongs.

The medicine was formerly thought to be obtained from the *Quassia amara*; but more than twenty years since, Lamarck stated that in consequence of the scarcity of this tree, the *Quassia excelsa* had been resorted to as a substitute, and the Pharmacopœias at present agree in acknowledging the latter as the officinal plant. It is, however, the opinion of Martius, that the genuine quassia of Surinam is the *Q. amara*; and we shall, therefore, give a brief description of both species.

Quassia excelsa. Willd. *Sp. Plant.* ii. 569.—*Simaruba excelsa*, De Cand. *Prodrom.* i. 733; Hayne, *Darstel. und Beschreib.*, &c. ix. 16.—*Picræna excelsa*. Lindley, *Flor. Med.* 208. As its name imports, this is a lofty tree, attaining sometimes not less than one hundred feet in height, with a straight, smooth, tapering trunk, which is often three feet in diameter near its base, and covered with a smooth gray bark. The leaves are pinnate, with a naked petiole, and oblong pointed leaflets standing upon short footstalks, in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green colour, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. This species inhabits Jamaica and the Caribbean islands, where it is called *bitter ash*. The wood is the officinal portion.

Quassia amara. Willd. *Sp. Plant.* ii. 567; Woodv. *Med. Bot.* p. 574. t. 204. The bitter quassia is a small branching tree or shrub, with alternate leaves, consisting of two pairs of opposite pinnæ, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep green colour on their upper surface, and paler on the under. The common footstalk is articulated, and edged on each side with a leafy membrane. The flowers, which are hermaphrodite and decandrous, have a bright red colour, and terminate the branches in long racemes. The fruit is a two-celled capsule, containing globular seeds. The *Q. amara* is a native of Surinam, and is said also to grow in some of the West India islands. Its root, bark, and

wood were formerly officinal. They are all excessively bitter, as are also the leaves, flowers, and fruit, and in fact the whole plant. It is uncertain whether any of the produce of this tree reaches our markets.

Quassia comes in cylindrical billets of various sizes, from an inch to near a foot in diameter, and several feet in length. These are frequently invested with a whitish smooth bark, brittle and but slightly adherent, and possessing in at least an equal degree the virtues of the wood. Their shape and structure clearly evince that they are derived from the branches or trunk, and not, as some suppose, from the root of the tree. In the shops they are usually kept split into small pieces, or rasped.

Properties. The wood is at first whitish, but becomes yellow by exposure. It is inodorous, and has a purely bitter taste, which is surpassed by that of few other substances in intensity and permanence. It imparts all its active properties, with its bitterness and yellow colour, to water and alcohol. The name of *quassin* was given by Dr. Thomson to the aqueous extract of quassia; but improperly, as this preparation is of complex constitution. Dr. Winckler first obtained from the wood a bitter crystallizable principle, to which the name of *quassin* properly belongs; but there is some reason to suppose that as prepared by him it was not entirely free from saline impurities. The following process of Wiggers probably affords it in a purer state. A filtered decoction of quassia is evaporated to three quarters of the weight of the wood employed, slaked lime is added, and the mixture having been allowed to stand for a day, with occasional agitation, is again filtered. A considerable quantity of pectin, besides other substances, is thus separated. The clear liquor is evaporated nearly to dryness, and the resulting mass exhausted by alcohol of the sp. gr. 0.835, which leaves behind gum, common salt, nitre, &c. in large amount, and dissolves quassin with some common salt and nitre, and an organic substance of a brown colour. In order to separate the quassin from these latter principles, which are soluble in water, the solution is evaporated to dryness, the resulting mass is dissolved in the least possible quantity of absolute alcohol, a large proportion of ether is added, and the liquor, previously separated by filtration from the brown mass which the ether has thrown down, is evaporated to dryness; and this process is repeated, till the quassin remains behind quite colourless, and affords no evidence of the presence of the above-mentioned salts. Lastly, in order to obtain it in a crystalline form, to which it is not strongly disposed, pour the alcoholic solution mixed with ether upon a little water, and allow it to evaporate spontaneously. *Quassin* is white, opaque, unalterable in the air, inodorous, and of an intense bitterness, which in the solutions of this principle is almost insupportable. The bitterness is pure, and resembles that of the wood. When heated, quassin melts like a resin. It is but slightly soluble in water, which at 54° dissolves only 0.45 in 100 parts, and that slowly. By the addition of salts, especially of those with which it is associated in quassia, its solubility is strikingly increased. It is also but slightly soluble in ether, but is very soluble in alcohol, more so in that liquid hot than cold, and the more so the purer it is. Quassin is perfectly neuter, though both alkalies and acids increase its solubility in water. It is precipitated by tannic acid from its aqueous solution, which is not disturbed by iodine, chlorine, corrosive sublimate, solutions of iron, sugar of lead, or even the subacetate of lead. Its ultimate constituents are carbon, hydrogen, and oxygen.

Medical Properties and Uses. Quassia has in the highest degree all the properties of the simple bitters. It is purely tonic, invigorating the digestive organs, with little excitement of the circulation, or increase of animal

heat. It has not been very long known as a medicine. About the middle of the last century, a negro of Surinam, named Quassi, acquired considerable reputation in the treatment of the malignant fevers of that country, by a secret remedy, which he was induced to disclose to Mr. Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756; and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. But the quassia of Surinam is not now in use, having been superseded by the product of the *Quassia excelsa*, from the West Indies. This medicine is useful in all cases in which a simple tonic impression is desirable. It is particularly adapted to dyspepsia from debility of stomach, and to that weakened state of the digestive organs which sometimes succeeds acute disease. It may also be given with advantage in the remission of certain fevers in which tonics are demanded. No one at present would expect from it any peculiar controlling influence over malignant fevers. It is said to be largely consumed in England by the brewers, who employ it to impart bitterness to their liquors.

It is most conveniently administered in infusion or extract. (See *Extractum Quassiæ* and *Infusum Quassiæ*.) The difficulty of reducing the wood to powder, is an objection to its use in substance. It may, however, be employed in a dose varying from a scruple to a drachm, repeated three or four times a day.

This extensive genus comprises not less than eighty species, of which between thirty and forty are found within the limits of the United States. Many of these are applied to important practical purposes. In the northern hemisphere, the oak is the most valuable, as it is the most widely diffused of all forest trees. Notwithstanding the great number of species, few, comparatively, have found a place in the officinal catalogues. The *Q. robur* or common European oak, and the *Q. pedunculata* or European white oak,

are the only species admitted by the British Colleges. As these do not grow in the United States, and their products are not imported, it is unnecessary to treat of them particularly in this work. According to Michaux, they grow in the same countries, frequently together, constituting the greater part of the forests of Europe, and spreading over almost the whole northern section of Asia, and the northern coast of Africa. The *Q. pedunculata* is the common British oak, celebrated as well for its majestic growth and the venerable age which it attains, as for the strength and durability of its timber, and the high purposes to which it has been applied. Our own Pharmacopœia recognises only the *Q. alba* or white oak, and the *Q. tinctoria* or black oak; but several other species afford barks which are equally useful, and perhaps as much employed. Such are the *Q. falcata* or Spanish oak, and *Q. prinus* or white chestnut oak, and the *Q. montana* or rock chestnut oak. The remarks which follow in relation to the white oak bark, will apply also to that of the three last mentioned species. The bark of the *Q. tinctoria* is somewhat peculiar.

1. *Quercus alba*. Willd. *Sp. Plant.* iv. 448; Michaux, *N. Am. Sylv.* i. 17. Of all the American species, the *white oak* approaches nearest in the character of its foliage, and the properties of its wood and bark, to the *Q. pedunculata* of Great Britain. When allowed to expand itself freely in the open field, it divides at a short distance from the ground into numerous widely spreading branches, and attains under favourable circumstances a magnificent size. Its trunk and large branches are covered with a whitish bark, which serves to distinguish it from most of the other species. The leaves are regularly and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter, and till the circulation of the sap returns in spring. The acorns are large, ovate, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly an inch in length.

The white oak abounds in the Middle States, and extends also through the whole Union, though comparatively rare in the northern, southern, and western sections. It is the most highly valued for its timber of all the American oaks, with the exception of the *live oak* (*Q. virens*), which is preferred in ship-building. The bark is sometimes used for tanning, but that of the *red* and *Spanish oaks* is preferred for this purpose. All parts of the tree, with the exception of the epidermis, are more or less astringent, but this property predominates in the fruit and bark, the latter of which is the only officinal portion.

Oak bark, deprived of its epidermis, is of a light brown colour, of a coarse fibrous texture, and not easily pulverized. It has a feeble odour, and a rough, astringent, and bitterish taste. Water and alcohol extract its active properties. The chief soluble ingredients are tannin, gallic acid, and extractive matter. It is upon the tannin that its medical virtues as well as its use in the preparation of leather chiefly depend. The proportion of this ingredient varies with the size and age of the tree, the part from which the bark is derived, and even the season when it is gathered. It is most abundant in the young bark; and the English oak is said to yield four times as much in spring as in winter. Sir H. Davy found the inner bark most abundant in tannin, the middle portion or cellular integument much less so, and the epidermis almost wholly destitute as well of this principle, as of extractive. Vauquelin states that the infusion of oak bark does not, like that of galls, precipitate tartar emetic.

2. *Quercus tinctoria*. Willd. *Sp. Plant.* iv. 444; Michaux, *N. Am. Sylv.* i. 91. The black oak is one of our largest trees, frequently attaining the height of eighty or ninety feet. Its trunk is covered with a deeply furrowed bark, of a black or dark brown colour. The leaves are ovate oblong, pubescent, slightly sinuated, with oblong, obtuse, mucronate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup.

Black-oak bark has a more bitter taste than that of the other species, and may be distinguished also by staining the saliva yellow when it is chewed. Its cellular integument contains a colouring principle, capable of being extracted by boiling water, to which it imparts a brownish-yellow colour, which is deepened by alkalies, and rendered brighter by acids. Under the name of *quercitron*, large quantities of this bark, deprived of its epidermis and reduced to coarse powder, are sent from the United States to Europe, where it is used for dyeing wool and silk of a yellow colour. It contains also much tannin; but is less used in tanning than the other barks, in consequence of the colour which it imparts to the leather.

Medical Properties and Uses. Oak bark is astringent and somewhat tonic. It has been given with advantage in intermittent fever, obstinate chronic diarrhœa, and certain forms of passive hemorrhage; but it is not much employed as an internal remedy. Externally applied it is often productive of benefit. The decoction may be advantageously used as a bath, particularly for children, when a combined tonic and astringent effect is desirable, and the stomach is not disposed to receive medicines kindly. It has been employed in this way in marasmus, scrofula, intermittent fevers, chronic diarrhœa, and cholera infantum. As an injection in leucorrhœa, a wash in prolapsus ani and hemorrhoidal affections, and as a gargle in slight inflammation of the fauces, attended with prolapsed uvula, the decoction is often highly useful. Reduced to powder and made into a poultice, the bark was recommended by the late Dr. Barton as an excellent application in cases of external gangrene and mortification, and the infusion obtained from tanners' vats has been used beneficially as a wash for flabby, ill-conditioned ulcers.

The bark may be given internally in the form of powder, extract, or decoction. The dose of the powder is from thirty grains to a drachm, of the extract about half as much, of the decoction two fluidounces. (See *Decoctum Quercûs*.)

Black-oak bark is considered inferior to the white-oak as an internal remedy, in consequence of being more disposed to irritate the bowels.

The fruit of the oak is sometimes used as an astringent; and a decoction made from roasted acorns has been highly recommended by Hufeland as a remedy in scrofula.

Gen. Ch. *Calyx* five-leaved. *Petals* five, having the inner side of each claw furnished with a melliferous pore. *Seeds* naked, numerous. *Nuttall.*

Most of the plants belonging to this genus have the same acrid properties. Several of them grow together in our fields and pastures, and from their close resemblance, are confounded under the common name of *buttercup*, applied to them from the colour and shape of their flowers. Those which are most abundant are believed to have been introduced from Europe. Such are the *R. bulbosus*, *R. acris*, and *R. repens*, which, with the *R. sceleratus*, may be indiscriminately used. In Europe, the *R. sceleratus* appears to have attracted most attention; in this country, the *R. bulbosus*. The latter is the only one designated by our Pharmacopœia. The *R. acris* and *R. Flammula* are directed by the Dublin College.

Ranunculus bulbosus. Willd. *Sp. Plant.* ii. 1324; Bigelow, *Am. Med. Bot.* iii. 60. This species of crowfoot is perennial, with a solid, fleshy root (cormus), which sends up annually several erect, round, and branching stems, from nine to eighteen inches high. The radical leaves, which stand on long footstalks, are ternate or quinate, with lobed and dentate leaflets. The leaves of the stem are sessile and ternate, the upper more simple. Each stem supports several solitary, bright yellow, glossy flowers, upon furrowed, angular peduncles. The leaves of the calyx are reflexed or bent downwards, against the flowerstalk. The petals are obcordate and arranged so as to represent a small cup in shape. At the inside of the claw of each petal is a small cavity, which is covered with a minute wedge-shaped emarginate scale. The fruit consists of numerous naked seeds, collected in a spherical head. The stem, leaves, peduncles, and calyx are hairy.

In the months of May and June our pastures are everywhere adorned with the rich yellow flowers of this species of *Ranunculus*. Somewhat later the *R. acris* and *R. repens* begin to bloom, and a succession of similar flowers is maintained till September. The two latter species prefer a moister ground, and are found most abundantly in meadows. The *R. sceleratus* is found in ponds and ditches. In all these species, the whole plant is pervaded by a volatile acrid principle, which is dissipated by drying or by the application of heat. This principle may be separated by distillation. Dr. Bigelow found that water distilled from the fresh plant has an acrid taste, and produces when swallowed a burning sensation in the stomach; and that it retains these properties for a long time if kept in closely stopped bottles. The plant itself when chewed excites violent irritation in the mouth and throat; inflaming and even excoriating the tongue and inside of the cheeks and lips, if not quickly discharged. Both the root and herbaceous portion of the *R. bulbosus* are officinal.

Medical Properties and Uses. Crowfoot, when swallowed in the fresh state, produces heat and pain in the stomach, and if the quantity be considerable, may excite fatal inflammation. It is, however, never used internally. The property for which it has attracted the attention of physicians is that of inflaming and vesicating the skin; and before the introduction of the Spanish fly into use, it was much employed for this purpose. But the uncertainty and occasional violence of its action have nearly banished it from regular practice. While on some individuals it appears to produce scarcely any effect, on others it acts very speedily, exciting extensive and troublesome inflammation, which sometimes terminates in deep and obstinate ulcers. It probably varies in strength with the season; and, in the dried state, or boiled with water, it is wholly inert. The decoction, moreover, is inert in consequence of the escape of the acrid principle. Nevertheless, the plant has been very properly retained by the Pharmacopœia in the catalogue of medi-

cines of secondary importance; as occasions may occur when the practitioner in the country may find advantage in having recourse to its powerful rube-facient and epispastic operation. W.

RESINA. U.S., Lond., Ed.

Resin.

“The residuum after the distillation of the volatile oil from the turpentine of *Pinus palustris* and other species of *Pinus*.” U.S. “*Pinus sylvestris*. *Residuum resinæ liquidæ postquam terebinthinæ oleum destillatum est.*” Lond. “Residue of the distillation of the turpentine of various species of *Pinus* and *Abies*.” Ed.

Off. Syn. PINUS SYLVESTRIS. Resina. Dub.

Resine blanche, Resine jaune, Fr.; Fichtenharz, Germ.; Ræga di pino, Ital.; Resina de pino, Span.

After the distillation of the volatile oil from the turpentine, (see *Terebinthina*.) a resinous matter remains, which on the continent of Europe is called *colophony*, but in our language is commonly known by the name of *rosin*. It is the RESINA of the United States and London Pharmacopœias, and the RESINA FLAVA or *yellow resin*, of the Dublin College. When this, in a state of fusion, is strongly agitated with water, it acquires a distinct appearance, and is now denominated RESINA ALBA or *white resin*. Before describing these officinal substances, it may be proper to enumerate the characteristic properties of the proximate principles which chemists designate by the term resins.

Resins are solid, brittle, of a smooth and shining fracture, and generally of a yellowish colour and semitransparent. When perfectly pure they are probably inodorous and often insipid, but, as usually found, they have a slight odour, and a somewhat acrid or bitterish taste. Their sp. gr. varies from 0.92 to 1.2. They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are dissolved by ether and the essential oils, and generally by alcohol; and their alcoholic and ethereal solutions afford precipitates upon the addition of water. With pure potassa and soda they unite to form soaps which are soluble in water; and the same result takes place when they are heated with the solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mutual decomposition; and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.

Common or *yellow resin*, in its purest state, is beautifully clear and pellucid, but much less so as it is commonly found in the shops. Its odour and taste are usually in a slight degree terebinthinate; its colour yellowish-brown with a tinge of olive, and more or less dark according to its purity, and the degree of heat to which it has been exposed in its preparation. It is rather heavier than water. At 276° F. it fuses, is completely liquid at 306°, begins to emit bubbles of gas at 316°, and is entirely decomposed at a red heat. Its ultimate constituents are carbon, oxygen, and hydrogen, in variable proportions. It appears, from the researches of Unverdorben, to contain three distinct resinous bodies, two of which, denominated *pinic* and *silvic acids*, pre-existed in the turpentine, and the third, called *colophonic acid*, is formed by the agency of the heat in the process of distillation. The *pinic acid* is dissolved by cold spirit of the sp. gr. 0.865, and is thus separated from the *silvic acid*. It is obtained pure by adding to the solution a

spirituous solution of acetate of copper, dissolving the precipitated pinate of copper in strong boiling alcohol, decomposing this salt with a little muriatic acid, and adding water, which throws down the pinic acid in the form of a resinous powder. The *sylic acid* is obtained by treating the residue of the common resin with boiling spirit of the sp. gr. 0·865, which dissolves it, and lets it fall upon cooling. Both of these resinous acids are colourless. The pinic acid is soluble in weak cold alcohol; the sylic acid is insoluble in the same menstruum when cold, but is dissolved by it when boiling hot, and by strong alcohol at all temperatures. The salts which they form with the alkalies are soluble, those with the earths and metallic oxides, insoluble in water. *Colophonic acid* differs from the others in having stronger acid properties, and in being less soluble in alcohol. It is of a brown colour, and common resin is more or less coloured in proportion to the quantity of this acid which it contains. (*Kane's Chemistry*.) The experiments of Unverdorben were made with European colophony. It is somewhat uncertain whether exactly the same results would be afforded by the common resin of this country, which is obtained from a different species of pine.

White resin differs from the preceding only in being opaque and of a whitish colour. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent.

Medical Uses. Resin is important as an ingredient of ointments and plasters; but is never used internally.

RHAMNUS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Rhamnaceæ.

Gen. Ch. Calyx tubular. Corolla scales defending the stamens, inserted into the calyx. *Berry. Willd.*

Rhamnus catharticus. Willd. *Sp. Plant.* i. 1092; Woodv. *Med. Bot.* p. 594. t. 210. The purging buckthorn is a shrub seven or eight feet high, with branches terminating in a sharp spine. The leaves are in fascicles, on short footstalks, ovate, serrate, veined. The flowers are usually diœcious, in clusters, small, greenish, peduncled, with a four-cleft calyx, and four very small scale-like petals, placed, in the male flower, behind the stamens, which equal them in number. The fruit is a four-seeded berry.

The shrub is a native of Europe, and is said to have been found growing wild in this country. It was first discovered in the Highlands of New York by Dr. Barratt. (*Eaton's Manual*.) It flowers in May and June, and ripens its fruit in the latter part of September. The berries are the

officinal portion. When ripe they are about the size of a pea, round, somewhat flattened on the summit, black, smooth, shining, with four seeds surrounded by a green, juicy parenchyma. Their odour is unpleasant, their taste bitterish, acrid, and nauseous. The expressed juice has the colour, odour, and taste of the parenchyma. It is reddened by the acids, and from deep green is rendered light green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness with the addition of lime or an alkali, it forms the colour called by painters *sap-green*. The dried berries of another species, *R. infectorius*, yield a rich yellow colour, for which they are much employed in the arts under the name of *French berries*.

Vogel obtained from the juice of the berries a peculiar colouring matter, acetic acid, mucilage, sugar, and a nitrogenous substance. Hubert found green colouring matter, acetic and malic acids, brown gummy matter, and a bitter substance which he considered as the purgative principle and supposed to resemble cathartin. M. Fleury obtained a peculiar crystallizable principle, which is contained both in the expressed juice and the residue remaining after expression, and for which he proposed the name of *rhamnin*; but he did not ascertain whether it possessed cathartic properties. (See *Journ. de Pharm.* xxvii. 666.)

Medical Properties and Uses. Both the berries and the expressed juice are actively purgative; but, as they are apt to occasion nausea, and severe griping pain in the bowels, with much thirst and dryness of the mouth and throat, they are now little employed. They formerly enjoyed considerable reputation as a hydragogue cathartic in dropsy; and were given also in rheumatism and gout. The only shape in which they are used in this country is that of the syrup, which is sometimes, though rarely, added to hydragogue or diuretic mixtures. (See *Syrupus Rhamni*.)

The dose of the recent berries is about a scruple, of the dried berries a drachm, and of the expressed juice a fluidounce.

Notwithstanding the length of time that rhubarb has been in use, and the attention which it has received from naturalists, the question yet remains unsettled from what precise plant it is derived. The remoteness of the region where it is collected, and the jealous care with which the monopoly of the trade in this drug is guarded, have prevented any accurate information on the subject. All that we certainly know, is that it is the root of

one or more species of Rheum. It is true that the Pharmacopœias undertake to designate the particular species. Thus, the London College recognises the *R. palmatum*, the Dublin both this and the *R. undulatum*, and in the United States Pharmacopœia the drug is referred to the *R. palmatum* and other species not particularized. But the evidence in favour of either of these species is by no means unequivocal, as will appear from the following brief history.

The terms *rha* and *rheon*, from the former of which were derived the names *rhabarbarum* and *rhubarb*, and from the latter the botanical generic title *Rheum*, were applied by the ancients to a root which came from beyond the Bosphorus, and which is supposed, though upon somewhat uncertain grounds, to have been the product of the *Rheum Rhaponticum*, growing on the banks of the Caspian sea and the Wolga. This species was also at one time believed to be the source of the medicine now in use; but the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not till the year 1732 that any probable information was obtained as to its real origin. At that time plants were received from Russia by Jussieu in France, and Rand in England, which were said to be of the species which afforded the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum Rhabarbarum*, a title which has since given way to *Rheum undulatum*. At a subsequent period, Kaew Boerhaave obtained from a merchant who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant which produced the root he sold. These seeds having been planted, yielded two species of Rheum, the *R. undulatum*, and another which Linnæus pronounced to be distinct, and named *R. palmatum*. Seeds transmitted by Dr. Mounsey from St. Petersburg to Dr. Hope, and planted in the botanic garden at Edinburgh, produced the latter species; and the same was also raised at Upsal from a root received by Linnæus from De Gorter, and was described A. D. 1767 by the younger Linnæus, two years after the appearance of Dr. Hope's paper in the Philosophical Transactions. Thus far the evidence appears equally in favour of the *R. palmatum* and *R. undulatum*. The claims of another species were afterwards presented. Pallas, upon exhibiting the leaves of the *R. palmatum* to some Bucharian merchants, of whom he was making inquiries relative to the rhubarb plant, was told that the leaves of the latter were entirely different in shape; and the description he received of them corresponded more closely with those of the *R. compactum*, than of any other known species. Seeds of this plant were moreover sent to Miller from St. Petersburg, as those of the true Tartarian rhubarb. Within a few years the attention of naturalists has been called to a fourth species, for which the same honour is claimed. Dr. Wallich, superintendent of the botanical garden at Calcutta, received seeds which were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya mountains and the highlands of Tartary. These produced a species not previously described, which Dr. Wallich named *R. Emodi*, from the native title of the plant. It is the *R. australe* of Mr. Don and of Colebrooke; and has been ascertained to afford a root which, though purgative, is very unlike the officinal rhubarb. Other species have been found to grow in the Himalaya mountains, from which a kind of rhubarb used by the natives is said to be procured; but none of it reaches the markets of this country or Europe. From what has been said, it is obvious that no species yet mentioned can be considered as the undoubted source of commercial rhubarb; the plant having, in no instance, been seen and examined by naturalists in its native place. Sievers, an apothecary

sent to Siberia in the reign of Catharine II. with the view of improving the cultivation of the native rhubarb, asserts, from information given him by the Bucharians, that all the seeds procured under the name of true rhubarb are false, and pronounces "all the descriptions in the *Materia Medica* to be incorrect." This assertion, however, has no relation to the *R. australe* which has been subsequently described; but of this plant it is said that the roots dried by the medical officers of the British army differ from true rhubarb in appearance and power. Still, however, it is possible that the medicine is derived from one or more of the species alluded to; and if it should be objected that their roots, as cultivated in Europe, have not the precise qualities or composition of the Asiatic rhubarb, the answer is obvious, that the product of the same plant is often known to vary exceedingly with diversities of soil, climate, and culture.

All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerous very large petiolate leaves, and terminating in lengthened branching panicles composed of small and very numerous flowers, resembling those of the *Rumex* or dock. Botanists experience some difficulty in properly arranging the species, in consequence of the tendency of the cultivated plants to form hybrids; and it is frequently impossible to ascertain to which of the wild types the several garden varieties are to be referred. The following descriptions are from the *Flora Medica* of Dr. Lindley.

Rheum palmatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 358; Woodv. *Med. Bot.* p. 662. t. 231. "Leaves roundish-cordate, half palmate; the lobes pinnatifid, acuminate, deep dull green, not wavy, but uneven and very much wrinkled on the upper side, hardly scabrous at the edge, minutely downy on the under side; sinus completely closed; the lobes of the leaf standing forwards beyond it. Petiole pale green, marked with short purple lines, terete, obscurely channeled quite at the upper end. Flowering stems taller than those of any other species." This species is said to inhabit China in the vicinity of the great wall. It is cultivated extensively near Banbury in England for the sake of its root, which is generally admitted to approach more nearly in odour, taste, and the arrangement of its colours, to the Asiatic rhubarb than that of any other known species.

R. undulatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 357; Woodv. *Med. Bot.* 3d ed. v. 81. "Leaves oval, obtuse, extremely wavy, deep green, with veins purple at the base, often shorter than the petiole, distinctly and copiously downy on each side, looking as if frosted when young, scabrous at the edge; sinus open, wedge-shaped, with the lower lobes of the leaves turned upwards. Petiole downy, blood-red, semi-cylindrical, with elevated edges to the upper side, which is narrower at the upper than the lower end." This is a native of Siberia, and probably of Tartary and China. It was cultivated by the Russian government as the true rhubarb plant; but the culture has been abandoned. It contributes to the rhubarb produced in France, and, according to Stevenson and Churchill, is the source of the drug sold in the London herb shops as English rhubarb, though the accuracy of this statement is doubted by Lindley.

R. compactum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 358; Loudon's *Encyc. of Plants*, p. 336. "Leaves heart-shaped, obtuse, very wavy, deep green, of a thick texture, scabrous at the margin, quite smooth on both sides, glossy and even on the upper side; sinus nearly closed by the parenchyma. Petiole green, hardly tinged with red except at the

base, semi-cylindrical, a little compressed at the sides, with the upper side broad, flat, bordered by elevated edges, and of equal breadth at each end." This plant is said to be a native of Tartary and China. It is one of the garden rhubarbs, and is cultivated in France for its root.

R. australe. Don, *Prod. Flor. Nepal.* p. 75.—*R. Emodi*. Wallich; Lindley, *Flor. Med.* p. 354; Hooker, *Bot. Mag.* t. 3508. "Leaves cordate, acute, dull green, but little wavy, flattish, very much wrinkled, distinctly rough, with coarse short hairs on each side; sinus of the base distinctly open, not wedge-shaped but diverging at an obtuse angle, with the lobes nearly turned upwards. Petioles very rough, rounded-angular, furrowed; with the upper side depressed, bordered by an elevated edge, and very much narrower at the upper than the lower end." The root of this species was at one time strongly maintained to be the source of officinal Asiatic rhubarb; but a specimen received by Dr. Pereira from Dr. Wallich was found to have scarcely any resemblance to it. The plant has been cultivated both in Europe and this country, and its petioles answer well for tarts, &c.

R. Rhaponticum. Willd. *Sp. Plant.* ii. 488; Lindley, *Flor. Med.* p. 357; Loudon's *Encyc. of Plants*, p. 335. "Leaves roundish-ovate, cordate, obtuse, pale green, but little wavy, very concave, even, very slightly downy on the under side, especially near the edge, and on the edge itself; scabrous at the margin; sinus quite open, large, and cuneate. Petiole depressed, channeled on the upper side, with the edges regularly rounded off, pale green, striated, scarcely scabrous. Panicles very compact and short, always rounded at the ends, and never lax as in the other garden species. Flowering stem about three feet high." The Rhapontic rhubarb grows upon the banks of the Caspian Sea, in the deserts between the Wolga and the Oural, and on the mountains of Krasnojarsk in Siberia. It is said also to grow upon the borders of the Euxine. It is cultivated abundantly as a garden plant in Europe and this country; and large quantities of the root are produced for sale in France.

Besides the species above described, the *R. leucorrhizum* growing in the Kirghese desert in Tartary, the *R. Caspicum* from the Altai mountains, and the *R. Webbianum*, *R. speciforme*, and *R. Moorcraftianum*, natives of the Himalaya mountains, and *R. crassinervium* and *R. hybridum*, cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives, or possess properties more or less analogous to those of officinal rhubarb, though they have not entered into general commerce.

The leafstalks of the different species of Rheum have a pleasant acid taste, and are used for making tarts and pies, which are not unlike those made with gooseberries. It is for this purpose only that the plants are cultivated in the United States. Lindley states that the *R. Rhaponticum*, *R. hybridum*, and *R. compactum*, and hybrid varieties of them, are the common garden rhubarbs.

In relation to the culture and preparation of rhubarb, our information is almost as uncertain as on the subject of its natural history. The accounts received from the Bucharian merchants are very discordant, and few intelligent travellers have penetrated into the country where the medicine is collected. We shall present, however, a brief abstract of what we have been able to collect upon the subject from the authorities we have consulted.

Rhubarb is produced abundantly in the elevated lands of Tartary about the lake Koko Norr, and is said to be cultivated in the neighbouring Chinese province of Shen-see, and in that of Setchuen. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb are

exclusively derived; but the root is also collected in Boutan and Thibet, on the north of the Himalaya mountains; and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. We are told by Mr. Bell, who, on a journey from St. Petersburg to Pekin, had an opportunity of observing it in a growing state, that it is not cultivated by the Tartars, but springs up spontaneously in tufts at uncertain distances, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the grass prevents their access to the soil. The root is not considered sufficiently mature for collection till it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground it is cleaned, deprived of its cortical portion and of the smaller branches, and then divided into pieces of a convenient size. These are bored with holes, and strung upon cords to dry, according to Mr. Bell, about the tents and on the horns of the sheep; according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Boutan, the roots are hung up in a kind of drying room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root; and Sievers states, that a year sometimes elapses from the period of its collection before it is ready for exportation. A very large proportion of its weight is lost in drying, according to some accounts four-fifths, to others not less than seven-eighths. It is probably in order to favour the drying that the bark is removed. The trade in rhubarb is said to centre in the Chinese town of Si-nin, where a Bucharian company or family is established, which possesses a monopoly of this trade, in consideration of a certain tribute paid to the government. To this city the rhubarb is brought from the various places of its collection, and having been duly assorted and undergone further preparation, is transmitted partly to Russia, partly to the coast of China; so that the drug which reaches us through St. Petersburg, is procured from the same neighbourhood with that imported from Canton. But it will soon be seen that there are differences between the Russian and Chinese rhubarb, which would seem to indicate a different origin, and might authorize doubts as to the entire accuracy of the above accounts. It is at least probable that the drug produced in the province of Setchuen, whence the best China rhubarb is said to be brought, takes a more direct route to the coast than that through the town of Si-nin. Besides the two commercial varieties just mentioned, a third occasionally comes to us from Europe, where the cultivation of rhubarb has been carried on for some time with success, especially in France, Belgium, and Great Britain. Of these three varieties we shall treat under different heads.

1. Chinese Rhubarb.

India Rhubarb. Rheum Sinense vel Indicum. Much the largest proportion of rhubarb consumed in this country is brought from Canton. Though somewhat inferior to the Russian, its comparative cheapness gives it a decided preference in our markets; and when of good quality it does not disappoint the expectations of the physician.

It is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty brownish-yellow colour externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered

smooth and somewhat powdery by attrition. The best pieces are heavier than the Russian rhubarb, have a texture rather close and compact, and when broken present a ragged uneven surface, variegated with intermingled shades of dull red, yellowish, and white, which are sometimes diversified or interrupted by darker colours. The pieces are generally perforated with small holes intended for convenience of suspension during the drying process; and portions of the suspending cord are not unfrequently found remaining in the holes. Chinese rhubarb has a peculiar somewhat aromatic smell, and a bitter astringent taste, is gritty when chewed, imparts a yellow colour to the saliva, and affords a yellowish powder with a reddish-brown tinge. With the pieces of good quality others often come mingled, which are defective from decay or improper preparation. These are usually lighter, and of a dark or russet colour. Like all the other varieties of rhubarb, this is liable to be attacked by worms; and in almost every large parcel, pieces may be found which have suffered from this cause. The want of proper care in its selection by the Chinese merchants, and the exposure incident to a long sea-voyage, are causes which contribute to its inferiority to the Russian rhubarb. As the whole contents of the chest imported are usually powdered together, including the worst as well as the best pieces, it follows that the powder is inferior in efficacy to the selected and sound pieces.

In the last edition of this work, we noticed a variety of rhubarb imported from Canton, which was evidently prepared, before leaving China, so as to resemble the Russian, having an angular surface, as if pared with a knife. The pieces were obviously selected with great care, as they were remarkably free from defects. But in most of those which came under our notice, the small penetrating hole was observable, which characterizes the Chinese rhubarb, though it had in some instances been filled with the powdered root, so as in some measure to conceal it. Besides, the colours were not quite so bright as those of Russia rhubarb. This is undoubtedly the variety described by Pereira, under a distinct head, as the *Dutch-trimmed* or *Batavian rhubarb*, and considered by him as probably Bucharian or Russian rhubarb of inferior quality, sent by the way of Canton. A sufficient proof, we think, that this is not the case, is the presence in most pieces of the small penetrating hole, occasionally filled with remains of the cord, and in some pieces almost shaved away in the paring process. We have never seen such a hole in any piece of true Russian rhubarb, which does not appear to be strung up like the Chinese when dried.

2. Russian Rhubarb.

Turkey Rhubarb. Bucharian Rhubarb. Rheum Russicum vel Turcicum. The rhubarb taken to Russia from Tartary undergoes a peculiar preparation, in conformity with the stipulations of a contract with the Bucharian merchants, who furnish the supply. The best is selected, and each piece perforated in order to ascertain whether it is sound in the centre. From Si-nin it is conveyed by the Bucharian merchants to the frontier town of Kiachta, where it undergoes a rigid inspection by an apothecary stationed at that place by the Russian government. All those pieces which do not pass examination are committed to the flames; and the remainder is sent to St. Petersburg. This variety is sometimes called *Turkey rhubarb*, from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Natolia. The circumstance of the identity of the Russian and Turkey

rhubarb, and their decided difference from the Chinese, would appear to indicate a distinct origin for the two varieties.

The pieces of Russian rhubarb are irregular, and somewhat angular, appearing as if the bark had been shaved off longitudinally by successive strokes of a knife, and a portion of the interior substance removed with each shaving. They have a cleaner and fresher appearance than the Chinese, and their colour both internally and externally, though of the same general character, is somewhat more lively. They are less compact and heavy; and are cut with less facility, owing to their giving away before the knife. Another distinction is the character of the perforations, which in the Russian rhubarb are large, frequently reaching only to the centre, and evidently made for the purpose of inspection; while in the Chinese they are small, penetrate completely through the pieces, and were intended for the passage of a suspending cord. The taste and smell of the former closely resemble those of the latter, except that the Russian is rather more aromatic. There is the same crackling under the teeth, and the same yellow stain imparted to the saliva; but the colour of the powder in this variety is a bright yellow, without the brownish tinge exhibited by the Chinese. When thin slices, previously boiled in water are examined by the microscope, they exhibit numerous clusters of minute crystals of oxalate of lime. Mr. Quekett found between 35 and 40 grains of them in 100 grains of the root. They are observed both in the Russian and Chinese rhubarb.

The care which renders the Russian rhubarb so free from defects, tends greatly to enhance its price, and consequently to limit its consumption. Its great comparative value in the market has led to frequent attempts at adulteration; and the pieces of Chinese rhubarb are sometimes cut down and prepared so as to resemble the Russian. The fraud, however, may be detected by adverting to the peculiarities in texture, colour, and weight, by which the varieties are distinguished, and to the occasional presence of the small penetrating hole or vestiges of it. We have seen a specimen in which the hole was enlarged at its two extremities, and closed by powder in the middle, with the view of imitating the larger perforations of the Russian pieces. Sometimes the worm-eaten pieces are made to resemble the sound, by filling up the holes with a mixture of pulverized rhubarb and mucilage, and covering over the surface with the powder. By removing this the fraud is at once revealed.

3. *European Rhubarb.*

In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plants have been cultivated for many years; and considerable quantities of the root are annually brought into the market. It is imported into this country from England and France.

English Rhubarb. This comes in two forms. In one, the root is cut and perforated in imitation of the Russian. The pieces are of various shape and size, sometimes cylindrical, but more commonly flat, or somewhat lenticular, and of considerable dimensions. In the other, the pieces are somewhat cylindrical, five or six inches long by an inch or less in thickness, and more or less irregular upon the surface, as if they had shrunk unequally in drying. This is called *stick rhubarb* in England, and is the kind we have most frequently met with in our shops. English rhubarb is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is of a redder colour, and when broken exhibits a more compact and

regular marbling; the pinkish lines being arranged in a radiated manner from the centre towards the circumference. The powder also has a deeper reddish tint. The odour is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous with little bitterness; and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colours the saliva. Few crystals of oxalate of lime are discoverable by means of the microscope. The roots of the different species are not distinguishable in commerce.

French Rhubarb. Rhapontic Rhubarb. Krimea Rhubarb. The rhubarb produced in France is at present, according to Guibourt, chiefly from the *R. Rhaponticum*, *R. undulatum*, and *R. compactum*; that of the *R. palmatum*, which most closely resembles the Asiatic, having been found to degenerate so much, as not to be a profitable object of culture. Most of the French rhubarb is produced in the neighbourhood of L'Orient, in the department of Morbihan; and the spot where it is grown has, from this circumstance, received the name of *Rheumpole*. Two kinds are described by Guibourt, both under the name of *Rhapontic root*. One proceeds from the *R. Rhaponticum*, growing in the gardens in the environs of Paris; the other, from this and the two other species above mentioned, cultivated at Rheumpole. The former is in pieces of the size of the fist or smaller, ligneous in their appearance, of a reddish-gray colour on the outside, internally marbled with red and white arranged in the form of crowded rays proceeding from the centre to the circumference, of an odour like that of Asiatic rhubarb, but more disagreeable, of a mucilaginous and very astringent taste, not crackling under the teeth, but tinging the saliva yellow, and affording a reddish-yellow powder. The pieces of the latter are irregularly cylindrical, three or four inches long and from one to two or even three inches thick, less ligneous in appearance than the preceding, and externally of a pale or brownish-yellow colour less inclining to redness. In exterior aspect, this variety bears considerable resemblance to Chinese rhubarb; but may be distinguished by its more disagreeable odour, its astringent and mucilaginous taste, its want of the crackling under the teeth, and its radiating fracture, in which properties it is similar to the preceding variety. Considerable quantities of this drug have been imported into the United States from France, under the name of *Krimea rhubarb*; and it is sometimes employed, we fear, to adulterate the powder of the Chinese rhubarb. It appears to have displaced in France the *Rhapontic root* formerly imported from the Euxine. Whether from difference in species, or from the influence of soil and climate, none of the European rhubarb equals the Asiatic in purgative power.*

Choice of Rhubarb. In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a lively colour, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odour decidedly aromatic, of a bitter and astringent not mucila-

* Besides the varieties of rhubarb above described others are noticed by writers. Pallas speaks of a *white rhubarb*, brought to Kiachta by the Bucharian merchants who conveyed to that place the drug for Russian commerce. It was white as milk, of a sweet taste, and equal to the best rhubarb in quality. It is supposed to be the product of the *R. leucorrhizum*. The *Himalaya rhubarb* is produced by the *R. australe*, and other species mentioned in the text as growing in the Himalaya mountains. According to Dr. Royle, it makes its way to the lower countries in Hindostan, where it sells for one-tenth of the price of the best rhubarb. Mr. Twining tried it in the Hospital at Calcutta, and found it superior as a tonic and astringent to Russia rhubarb, and nearly equal to it in purgative power.

ginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Rotten, worm-eaten, or otherwise inferior rhubarb, is often powdered and coloured yellow with turmeric; and the shavings left, when Chinese rhubarb is cut to imitate the Russian, are applied to the same purpose.

Chemical Properties. Rhubarb yields all its active properties to water and alcohol. The infusion is of a dark reddish-yellow colour, with the taste and odour of rhubarb; and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By long boiling the virtues of the medicine are diminished, in consequence probably of the evaporation of a volatile ingredient in which they partly reside. Many attempts have been made to analyze this important root, with various results. Among them, are those of the two Henrys and Caventou of Paris, Brande of London, Peretti of Rome, and Horneman and Brandes of Germany. The most recent is that of Brandes, who found in 100 parts of Chinese rhubarb, 2 of pure *rhabarbaric acid*, 7.5 of the same acid impure, 2.5 of gallic acid, 9.0 of tannin, 3.5 of colouring extractive, 11.0 of uncrystallizable sugar with tannin, 4.0 of starch, 14.4 of gummy extractive, 4.0 of pectic acid, 1.1 of malate and gallate of lime, 11.0 of oxalate of lime, 1.5 of sulphate of potassa and chloride of potassium, 1.0 of silica, 0.5 of phosphate of lime and oxide of iron, 25.0 of lignin, and 2.0 of water. Professor Dulk, of Königsberg, has shown that the *rhabarbaric acid* of Brandes is for the most part formed during the process for its extraction; and believes that it results from the reaction of the atmospheric air, assisted by the reagents employed, upon another principle, which he succeeded in isolating and named *rhein*. That portion of the rhabarbaric acid which exists ready formed in rhubarb may be extracted by macerating the powdered root in ether, distilling off most of the ether, and allowing the remainder to evaporate spontaneously. Crystals are left, which may be purified by repeated solution and crystallization in alcohol. The medical properties of rhubarb, being themselves diversified, probably depend upon different principles. Approaches seem to have been frequently made towards the discovery of the purgative principle, but not with complete success, unless the *rhein* of Professor Dulk be allowed this rank. The *caphopicrite*, or yellow colouring matter of M. Henry, has been shown to be a complex substance. The same is the case with the different matters obtained by various chemists and described by the name of *rhabarbarin*. The *rhabarbaric acid* of Brandes, though regarded by that chemist as the active principle, can have little claim to be so considered; as it has no remarkable taste, and six grains of it given to a young man produced griping, but did not purge. We may consider the *rhein* above mentioned to be, as asserted, the purgative principle, until proved to be otherwise.

Rhein is a reddish-yellow substance, which strongly attracts moisture from the air, and is, therefore, not easily obtained crystallized. Its taste and odour are closely analogous to those of the root itself. It is soluble in water, alcohol, and ether, but most readily in diluted alcohol; and forms yellow or reddish-yellow solutions. It reddens litmus; when heated, melts and diffuses vapours having the odour of rhubarb; is inflammable; forms compounds with alkaline bases and especially with ammonia, having a blood-red tint; and, when treated with nitric acid, yields a yellow solution which is rendered turbid by water, and deposits a yellow powder. It was obtained by Professor Dulk in the following manner. The root was macerated with

solution of ammonia, and to the red mucilaginous liquor which resulted, carbonate of baryta was added. When the red colour of the liquor ceased to be changed to green by a salt of iron, the baryta was separated from its combination with the rhein by sulphuric or fluosilicic acid, added until the liquor exhibited an acid reaction. The whole mixture was then evaporated, and the residue treated with alcohol of the sp. gr. 0.802, saturated with ammonia. The solution, which was of a blood-red colour, was filtered and evaporated nearly to dryness, when solution of ammonia was again added, and the liquid again filtered, in order to separate a yellow powder, which was the rhabarbaric acid of Brandes. The red filtered liquor was precipitated by subacetate of lead; the precipitate was washed with small quantities of water, mixed with a little ammonia, and having been dried, was treated with alcohol of 0.820, and decomposed by a current of sulphuretted hydrogen. The solution, which was very yellow, being filtered and evaporated, yielded the rhein in the form of a reddish-yellow mass, mingled with some prismatic crystals, which, by the absorption of moisture, soon lost their form. (*Journ. de Pharm.* xxv. 261, from *Arch. der Pharm. des Apothek. Vereins in Nord-Deutschland*, bd. xvii.)

There are other interesting principles in rhubarb. Some have been disposed to ascribe its odour to a volatile oil; but this has not been isolated; and the odour probably resides in the rhein, which is volatilizable. Tannin is an important constituent. It is of that variety which precipitates the sesquisalts of iron of a greenish colour. Whether there is a bitter principle distinct from the purgative has not been positively determined. The oxalate of lime is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constituted nearly one-third, and Quekett found, as already stated, between 35 and 40 per cent.; while Brandes obtained only 11, and Schrader only 4.5 parts in the hundred. Little or no difference of composition has been found between the Russian and Chinese rhubarb. The European contains but a small proportion of the oxalate of lime, and is therefore less gritty when chewed. It contains, however, more tannin and starch than the Asiatic varieties.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapour of rhein. Its infusion is reddened by the alkalis, in consequence of their union with rhein and rhabarbaric acid. It yields precipitates with gelatin, the sesquisalts of iron, acetate of lead, nitrate of protoxide of mercury, nitrate of silver, protochloride of tin, lime-water, solutions of quinia, and gelatin. It is probable that nitric acid, which occasions at first a turbidness, and afterwards the deposition of a yellow precipitate, acts by oxidizing the *rhein*, and thus converting it into rhabarbaric acid, which is but very slightly soluble in water. The substances producing precipitates may be considered as incompatible.

Medical Properties and Uses. The medical properties of rhubarb are peculiar and valuable. Its most remarkable singularity is the union of a cathartic with an astringent power; the latter of which, however, does not interfere with the former, as the purgative effect precedes the astringent. It is also tonic and stomachic; invigorating, in small doses, the powers of digestion. It is not probable that these properties reside in a single proximate principle; and, as rhubarb owes its chief value to their combination, it is not to be expected that chemical analysis will be productive of the same practical advantages in this, as in some other medicines, the virtues of which are

concentrated in one ingredient. In its purgative operation rhubarb is moderate, producing fecal rather than watery discharges, and appearing to affect the muscular fibre more than the secretory vessels. It sometimes occasions griping pains in the bowels. Its colouring principle is absorbed, and may be detected in the urine. By its long continued use, the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses to acquire a purgative property.

The circumstances of disease to which it is applicable may be inferred from its peculiar properties. When the stomach is enfeebled and the bowels relaxed, at the same time that a gentle cathartic is required, rhubarb, as a general rule, is preferable to all others. Hence its use in dyspepsia attended with constipation, in diarrhœa when purging is indicated, in the secondary stages of cholera infantum, in chronic dysentery, and in almost all typhoid diseases when fecal matter has accumulated in the intestines, or the use of cathartic medicine is necessary to prevent such accumulation. When employed in cases of habitual constipation, its astringent tendency should be counteracted by combining it with soap. Magnesia is also an excellent associate in disorders of the stomach and bowels. By combination with other cathartics, rhubarb frequently acquires additional activity, while it gives increased efficiency to the substance with which it is associated. A mixture of calomel and rhubarb is a brisk and powerful cathartic, much used in the commencement of our bilious fevers. As a general rule, rhubarb is not applicable to cases attended with much inflammatory action. Its griping effect may be counteracted by combining it with aromatics.

The dose of rhubarb as a purgative is from twenty to thirty grains, as a laxative and stomachic from five to ten grains. European rhubarb must be given in double or treble the dose to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently given in the shape of pill, combined with an equal proportion of soap, when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted to children. The syrup and tincture are also highly useful preparations. They are all officinal.

By the roasting of rhubarb its purgative property is diminished, probably by the volatilization of the rhein, while its astringency remains unaffected. This mode of treatment has, therefore, been sometimes resorted to in cases of diarrhœa. By long boiling the same effect is said to be produced.

Powdered rhubarb has been usefully applied to indolent and sloughing ulcers. It is said to have proved purgative when sprinkled over a large ulcerated surface; and the same effect is asserted to have been produced by rubbing it, mingled with saliva, over the abdomen.

Papaver Rhœas. Willd. *Sp. Plant.* ii. 1146; Woodv. *Med. Bot.* p. 387.

t. 139. The red or corn poppy is distinguished by its hairy stem, which is branched and rises about a foot in height, by its incised pinnatifid leaves, by its urn-shaped capsule, and by the full, bright, scarlet colour of its petals. It is a native of Europe, where it grows wild in great abundance, adorning especially the fields of grain with its brilliant flower. It has been introduced and naturalized in this country.

Its capsules contain the same kind of milky juice as that found in the *P. somniferum*, and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. The petals are the officinal portion. They have a narcotic smell, and a mucilaginous, slightly bitter taste. By drying, they lose their odour, and assume a violet-red colour. Chevallier detected a very minute proportion of morphia in an extract obtained from them (*Dict. des Drogues*); but their operation on the system is exceedingly feeble, and they are valued more for their beautiful scarlet colour, which they communicate to water, than for their medical virtues. A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections; but is now little esteemed, except for its fine colour.

RHUS GLABRUM. *U.S. Secondary.**Sumach.*

“The fruit of *Rhus glabrum*. Baccæ. The berries.” *U. S.*

Rhus. *Sex. Syst.* Pentandria Trigynia.—*Nat. Ord.* Anacardiaceæ.

Gen. Ch. Calyx five-parted. Petals five. Berry small, with one nuciform seed. *Nuttall.*

Of this genus there are several species which possess poisonous properties, and should be carefully distinguished from that here described. For an account of them the reader is referred to the article *Toxicodendron*.

Rhus glabrum. Willd. *Sp. Plant.* i. 1478. This species of *Rhus*, called variously smooth sumach, Pennsylvania sumach, and upland sumach, is an indigenous shrub from four to twelve feet high, with a stem usually more or less bent, and divided into straggling branches, covered with a smooth light gray or somewhat reddish bark. The leaves are upon smooth petioles, and consist of many pairs of opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their colour changes to a beautiful red. The flowers are greenish-red, and disposed in large, erect, terminal, compound thyrses, which are succeeded by clusters of small crimson berries covered with a silky down.

The shrub is found in almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers

appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and said to be used in tanning leather and in dyeing. Excrescencies are produced under the leaves resembling galls in character, and containing large quantities of tannin and gallic acid. These have been used as a substitute for the imported galls by Dr. Walters of New York, who thought them, in every respect, preferable. They may be collected at little expense, as they are produced very abundantly, especially in the Western States. (*A. W. Ives' edition of Paris's Pharmacologia.*) But the only official part of the plant is the berries.

These have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. According to Mr. Cozzens of New York, the acid to which they owe their sourness is the malic, and is contained in the pubescence which covers their surface; as, when it is washed away by warm water, the berries are wholly free from acidity. Professor W. B. Rogers of Virginia found the acid combined with lime, in the state of bimalate.

Medical Properties and Uses. Sumach berries are astringent and refrigerant; and their infusion has been recommended as a cooling drink in febrile complaints, and a pleasant gargle in inflammation and ulceration of the throat. By Dr. Fahnestock an infusion of the inner bark of the root, employed as a gargle, is considered almost as a specific in the sore mouth attending inordinate mercurial salivation. (*Am. Journ. of Med. Sciences*, v. 61.) W.

ROSA. See ROSA CENTIFOLIA.

Rosa canina. Willd. *Sp. Plant.* ii. 1077; Woodv. *Med. Bot.* p. 493. t. 177. The dog rose, wild briar, or heptree, is a native of Europe, distinguished as a species by its glabrous ovate germs, its smooth peduncles, its prickly stem and petioles, and its ovate, smooth, rigid leaves. It rises eight or ten feet in height, and bears white or pale red flowers, having usually five obcordate fragrant petals. The plant has been introduced into this country, but is not much cultivated.

The fruit is fleshy, smooth, oval, red, and of a pleasant, sweet, acidulous taste; and contains sugar, and uncombined citric and malic acids.

The pulp, separated from the seeds and the silky bristles in which they are embedded, is employed in Europe for the preparation of a confection intended chiefly as an agreeable vehicle for other medicines.

Gen. Ch. Petals five. Calyx urceolate, five-cleft, fleshy, contracted at the neck. Seeds numerous, hispid, attached to the inner side of the calyx. *Willd.*

Rosa centifolia. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 495 t. 178. This species of rose has prickly stems, which usually rise from three to six feet in height. The leaves consist of two or three pairs of leaflets, with an odd one at the end, closely attached to the common foot-stalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, usually of a pale red colour, and supported upon peduncles beset with short bristly hairs. The germ is ovate, and the segments of the calyx semi-pinnate. The varieties of the *R. centifolia* are very numerous, but may be indiscriminately employed. The plant is now cultivated in gardens all over the world; but its original country is not certainly known. It has sometimes been mistaken for the damask rose, which is a distinct species.

The petals are the officinal portion. They are extremely fragrant, and have a sweetish, slightly acidulous, somewhat bitterish taste. Their odour is said to be increased by iodine. It depends on a volatile oil, which may be separated by distillation with water. (See *Oleum Rosæ*.) They should be collected when the flower is fully expanded, but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved fresh, for a considerable time, by compressing them with alternate layers of common salt in a well closed vessel, or beating them with twice their weight of that substance.

The petals are slightly laxative, and are sometimes administered in the form of syrup combined with cathartic medicines; but their chief use is in the preparation of rose-water. (See *Aqua Rosæ*.)

ROSA. See *ROSA CENTIFOLIA*.

Rosa Gallica. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 498. t. 179. This species is smaller than the *R. centifolia*, but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are

of a rich crimson colour, and less numerous than in the preceding species. In the centre is a crowd of yellow anthers on thread like filaments, and as many villose styles bearing papillary stigmas. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the South of Europe, and is cultivated in gardens throughout the United States.

The petals, which are the part employed, should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odour, which is less fragrant than that of the *R. centifolia*, is improved by drying. They have a velvety appearance, a purplish-red colour, and a pleasantly astringent and bitterish taste. Their constituents, according to M. Cartier, are tannin, gallic acid, colouring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassa, insoluble salts of lime, silica, and oxide of iron. (*Journ. de Pharm.* vii. 531.) Their sensible properties and medical virtues are extracted by boiling water. Their infusion is of a pale reddish colour, which becomes bright red on the addition of sulphuric acid. As their colour is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

Medical Properties and Uses. Red roses are slightly astringent and tonic, and were formerly thought to possess peculiar virtues. They are at present chiefly employed in infusion, as an elegant vehicle for tonic and astringent medicines.

ROSMARINUS. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatae.

Gen. Ch. Corolla unequal, with the upper lip two-parted. Filaments long, curved, simple, with a tooth. *Willd.*

Rosmarinus officinalis. Willd. *Sp. Plant.* i. 126; Woodv. *Med. Bot.* p. 329. t. 117. Rosemary is an evergreen shrub, three or four feet high, with an erect stem, divided into many long, slender, ash-coloured branches. The leaves are numerous, sessile, opposite, more than an inch long, about one-sixth of an inch broad, linear, entire, obtuse at the summit, turned backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish and somewhat downy beneath. The flowers are pale blue or white, of considerable size, and placed in opposite groups at the axils of the leaves, towards the ends of the branches. The seeds are four in number, of an oblong shape, and naked in the bottom of the calyx.

The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The flowering summits are the officinal portion.

These have a strong balsamic odour, which is possessed, though in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on a volatile oil which may be obtained by distillation. (See *Oleum*

Rosmarini.) The tops lose a portion of their sensible properties by drying, and become inodorous by age.

Medical Properties and Uses. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, &c., to which it imparts its agreeable odour and excitant property. It is sometimes added to sternutatory powders, and is used externally in connexion with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavour to the honey of the districts in which the plant abounds.

RUBIA. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Rubiaceæ. *Juss.*

Gen. Ch. Corolla one-petaled, bell-shaped. Berries two, one-seeded. *Willd.*

Rubia tinctorum. Willd. *Sp. Plant.* i. 603; Woodv. *Med. Bot.* p. 173. t. 67. The root of the *dyers' madder* is perennial, and consists of numerous long, succulent fibres, varying in thickness from the size of a quill to that of the little finger, and uniting at top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. These are slender, quadrangular, jointed, procumbent, and furnished with short prickles by which they adhere to the neighbouring plants upon which they climb. The leaves are elliptical, pointed, rough, firm, about three inches long and nearly one inch broad, having rough points on their edges and midrib, and standing at the joints of the stem in whorls of four, five, or six together. The branches rise in pairs from the same joints, and bear small yellow flowers at the summit of each of their subdivisions. The fruit is a round, shining, black berry.

The plant is a native of the South of Europe, and is cultivated in France and Holland. It is from the latter country that commerce derives its chief supply. The root, which is the part used, is dug up in the third summer, and, having been deprived of its cuticle, is dried by artificial heat, and then reduced to a coarse powder. In this state it is packed in barrels, and sent into the market.

The root consists of a reddish-brown bark, and a ligneous portion within. The latter is yellow in the recent state, but becomes red when dried. The powder, as kept in the shops, is reddish-brown.

Madder has a weak peculiar odour, and a bitterish astringent taste; and imparts these properties, as well as a red colour, to water and alcohol. It contains, according to M. Runge, five distinct colouring substances; a red, a purple, an orange, a yellow, and a brown. According to M. Decaisne, only yellow colouring matter is found in the recent root; and it is under the influence of atmospheric air that this changes to red. The most interesting of the colouring substances is the *alizarin* of Robiquet and Collin. This is of an orange-red colour, inodorous, insipid, crystallizable,

capable of being sublimed without change, scarcely soluble in cold water, soluble in boiling water, and very readily so in alcohol, ether, the fixed oils, and liquid alkalies. The alcoholic and watery solutions are rose-coloured; the ethereal, golden-yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-coloured lake is produced by precipitating a mixture of the solutions of alizarin and alum. Madder also contains sugar; and Döbereiner succeeded in obtaining alcohol from it by fermentation and distillation, without affecting its colouring properties. It is much used by the dyers.

Medical Properties and Uses. Madder was formerly thought to be emmenagogue and diuretic; and was used in amenorrhœa, dropsy, jaundice, and visceral obstructions. It is still occasionally prescribed in suppressed menstruation; but physicians generally have no confidence in its efficacy in this or any other complaint. When taken into the stomach it imparts a red colour to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in rachitis, but without any favourable result. The dose is about half a drachm, repeated three or four times a day. W.

RUBUS TRIVIALIS. U.S. Secondary.

Dewberry-root.

“The root of *Rubus trivialis*.” U. S.

RUBUS VILLOSUS. U.S. Secondary.

Blackberry-root.

“The root of *Rubus villosus*.” U. S.

RUBUS. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx five-cleft. Petals five. Berry compound, with one-seeded acini. Willd.

Of this extensive genus not less than twenty species are indigenous in the United States, where they are called by the various names of *raspberry*, *blackberry*, *dewberry*, *cloudberry*, &c. Most of them are shrubby or suffrutescent briars, with astringent roots and edible berries; some have annual stems without prickles. The only officinal species are the *R. trivialis* and *R. villosus*, which, so far as relates to their medical properties, are so closely alike as not to require a separate description.

1. *Rubus trivialis*. Michaux, *Flor. Americ.* i. 296. The *dewberry*, sometimes also called *low blackberry*, or *creeping blackberry*, has a slender, prickly stem, which runs along the ground, and occasionally puts forth roots. The leaves are petiolate, and composed of three or five leaflets, which are oblong oval, acute, unequally serrate, and somewhat pubescent. The stipules are awl-shaped. The flowers are large, white, and nearly solitary, with elongated pedicels, and peduncles which, like the leafstalks, are armed with recurved, hispid prickles. The petals are generally obovate, and three times longer than the calyx. In one variety they are orbicular. The plant grows abundantly in old fields and neglected grounds in the Middle and Southern States. Its fruit is large, black, of a very pleasant flavour, and ripens somewhat earlier than that of the *R. villosus*. Accord-

ing to Torrey and Gray, the dewberry of the Northern States is the *Rubus Canadensis* of Linn., or *R. trivialis* of Pursh. (*Flor. of N. Am.* i. 455.)

2. *R. villosus.* Willd. *Sp. Plant.* ii. 1085; Bigelow, *Am. Med. Bot.* ii. 160; Barton, *Med. Bot.* ii. 151. The stem of the blackberry is somewhat shrubby, from three to seven feet high, branching, more or less furrowed and angular, and armed with strong prickles. The smaller branches and young shoots are herbaceous. The leaves are ternate or quinate; the leaflets ovate, acuminate, unequally and sharply serrate, and pubescent on both sides; the footstalk and midrib usually armed with short recurved prickles. The flowers are large, white, and in erect racemes, with a hairy, prickly stalk. The calyx is short, with acuminate segments. The fruit is first green, then red, and when perfectly ripe, of a shining black colour, and very pleasant taste. It is a compound berry, consisting of numerous pulpy one-seeded globules or acini attached to the receptacle. This species of *Rubus* is, perhaps, the most abundant of those indigenous in the United States, growing in neglected fields, along fences, on the borders of woods, in forest glades, and wherever tillage or too much shade and moisture does not interfere with it. Its flowers appear from May to July, and its fruit is ripe in August.

The berries of both these species of *Rubus* are much used as food; and a jelly made from them is in great esteem as an article of diet, and even as a remedy in dysenteric affections. The roots only are officinal.

The blackberry root is branching, cylindrical, of various dimensions, from nearly an inch in thickness down to the size of a straw, ligneous, and covered with a thin bark, which is externally of a light brownish or reddish-brown colour, and in the dried root is wrinkled longitudinally. The dewberry root is usually smaller, without the longitudinal wrinkles, but with transverse fissures through the epidermis, and of a dark ash colour, without any reddish tinge. Both are inodorous. The bark in both has a bitterish strongly astringent taste, and the ligneous portion is nearly insipid, and comparatively inert. The smaller roots, therefore, should be selected for use; or, if the thicker pieces are employed, the cortical part should be separated, and the wood rejected. Their virtues are extracted by boiling water, and by diluted alcohol, and depend chiefly, if not exclusively, upon tannin, which experiment has proved to be an abundant constituent.

Medical Properties and Uses. Dewberry and blackberry roots are tonic and strongly astringent. They have long been a favourite domestic remedy in bowel affections; and from popular favour have passed into regular medical use. Given in the form of decoction, they are usually acceptable to the stomach, without being offensive to the taste; and may be employed with great advantage in cases of diarrhœa from relaxation of the bowels, whether in children or adults. We can add our own decided testimony to that of others who have spoken favourably of their use in this complaint; and there is no doubt that they are applicable to all other cases in which the vegetable astringents are found serviceable. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint; of which from one to two fluidounces may be given to an adult three or four times, or more frequently, during the twenty-four hours. The dose of the powdered root is twenty or thirty grains.

W.

RUMEX. *Lond.**Sorrel.*

“*Rumex acetosa. Folia.*” *Lond.*

Off. Syn. RUMEX ACETOSA. *Folia. Dub.*

Oseille des jardins, Fr.; Sauerampfer, Germ.; Acetosa, Ital.; Azedera, Span.

RUMEX. See RUMEX AQUATICUS.

Several species of *Rumex* have acid leaves, and are distinguished by the common name of *sorrel* from the others which are called *dock*. Two only deserve particular notice, the *R. Acetosa*, or common English sorrel, which is sometimes cultivated in our gardens, and the *R. Acetosella*, or common sorrel of our fields.

Rumex Acetosa. Willd. *Sp. Plant.* ii. 260; Woodv. *Med. Bot.* p. 660. t. 230. This is a perennial herbaceous plant, with a striated leafy stem, branching at top, and rising one or two feet in height. The radical leaves are narrow, oblong, arrow-shaped, and supported on long footstalks; those attached to the stem are alternate, pointed and clasping. The flowers are diœcious, in terminal panicles, and partly tinged of a red colour.

R. Acetosella. Willd. *Sp. Plant.* ii. 260; *Eng. Bot.* 1574. The common field sorrel is also an herbaceous perennial, with a stem from four to twelve inches high, and lanceolate-hastate leaves, having the lobes spreading or recurved. The male and female flowers are on separate plants. The valves are without grains. The flowers appear in May, June, and July. Though abundant in the light sandy or gravelly soils of this country, it is supposed by some botanists to have been introduced from Europe.

Sorrel leaves are agreeably sour, and without odour. Their acidity is dependent on the presence of binoxalate of potassa, with a small proportion of tartaric acid. Starch and mucilage are also among their constituents. Their taste is almost entirely destroyed by drying.

They are refrigerant and diuretic, and may be used with great advantage, as an article of diet, in scorbutic complaints. They are prepared in the form of salad, or boiled like spinage. The juice of the fresh leaves forms with water a pleasant acidulous drink, sometimes given in fevers. W.

RUMEX AQUATICUS. *Radix. Dub.**Water Dock Root.*RUMEX BRITANNICA. *U.S. Secondary.**Water Dock.*

“The root of *Rumex Britannica.*” *U.S.*

RUMEX OBTUSIFOLIUS. *U.S. Secondary.**Blunt-leaved Dock.*

“The root of *Rumex obtusifolius.*” *U.S.*

RUMEX. *Sex. Syst.* Hexandria Trigynia.—*Nat. Ord.* Polygonaceæ.

Gen. Ch. *Calyx* three-leaved. *Petals* three, converging. *Seed* one, three-sided. *Willd.* *Calyx* six-parted, persistent, the three interior divisions

petaloid, connivent. *Seed* one, three-sided, superior, naked. *Stigmata* multifid. *Nuttall.*

We have placed together the three officinal species of dock, because their virtues are so nearly alike that a separate consideration would lead to unnecessary repetition. The roots of several other species have been medically employed. Those of the *R. Patientia*, and *R. alpinus*, European plants, and of the *R. crispus*, *R. acutus*, and *R. sanguineus*, which belong both to Europe and the United States, may be used indiscriminately with those which are considered officinal. Several species of *Rumex* have acid leaves, which are sometimes used in medicine. Such are the *R. Acetosa*, *R. Acetosella*, and *R. scutatus*. These are more particularly noticed under the head of *Rumex*.

The docks are herbaceous plants with perennial roots. Their flowers are in terminal or axillary panicles. Some of the species are diœcious; but all those here described have perfect flowers.

1. *Rumex aquaticus*. Willd. *Sp. Plant.* ii. 255; Woodv. *Med. Bot.* p. 658. t. 229. The *water dock* has a large thick root, externally black, internally whitish, with an erect stem from three to five feet high, furnished with smooth, lanceolate, pointed leaves, of which the lower are cordate at their base. The three petals, or as some botanists consider them, the three interior divisions of the calyx, approach each other so as to assume a triangular shape, and in this state are called *valves*. These are large, ovate, entire, and are each furnished with a small, linear, often obscure grain, extending down the middle. The plant is a native of Europe, but naturalized in America. It grows in this country in small ponds and ditches, and flowers in July and August. It is thought to be the *Herba Britannica* of the ancients, celebrated for the cure of scurvy and diseases of the skin.

2. *R. Britannica*. Willd. *Sp. Plant.* ii. 250. This species is distinguished in the vernacular language by the name of *yellow-rooted water dock*. The root is large, dark on the outside, and yellow within. The stem is two or three feet high, and bears broad lanceolate, smooth, flat leaves, with the sheathing stipules slightly torn. The spikes of the panicle are leafless; the valves entire and all graniferous. The plant is indigenous, inhabiting low, wet places, and flowering in June and July.

3. *R. obtusifolius*. Willd. *Sp. Plant.* ii. 254; Loudon's *Encyc. of Plants*, p. 293. The root of the *blunt-leaved dock* is externally brown, internally yellow; the stem two or three feet high and somewhat rough; the radical leaves ovate cordate, obtuse, and very large; the valves dentate, and one of them conspicuously graniferous. It is a common weed in our rich grounds and pastures, but is supposed to have been introduced from Europe. Its flowers appear in June and July.

4. *R. crispus*. Willd. *Sp. Plant.* ii. 251. This common species, though not officinal, is perhaps equally entitled to notice with those which are so. It has a yellow, spindle-shaped root, with a smooth furrowed stem two or three feet high, and lanceolate, waved, pointed leaves. The valves are ovate, entire, and all graniferous. It is a native of Europe, and grows wild in this country. It is common in our dry fields and pastures, and about barn yards, and flowers in June and July.

Dock-root, from whatever species derived, has an astringent bitter taste, with little or no smell. It readily yields its virtues to water by decoction. According to Riegel, the root of the *R. obtusifolius* contains a peculiar principle called *rumicin*, resin, extractive matter resembling tannin, starch, mucilage, albumen, lignin, sulphur, and various salts, among which are the phosphate of lime, and different acetates and malates. *Rumicin* is said to

bear a close resemblance to the active principle of rhubarb. (*Journ. de Pharm. 3ème Série* i. 410.) The leaves of most of the species are edible, and are occasionally used as spinage. They are somewhat laxative, and form an excellent diet in scorbutic cases. The roots are used to dye a yellow colour.

Medical Properties and Uses. The medical properties of dock-root are those of an astringent and mild tonic. It is also supposed to possess an alterative property, which renders it useful in scorbutic disorders, and cutaneous eruptions, particularly the itch, in the cure of which it enjoyed at one time considerable reputation. It is said to have proved useful also in syphilis. Dr. Thomson found a decoction of the root of the *R. Patientia* very efficacious in obstinate ichthyosis. (*London Dispensatory*.) The *R. aquaticus*, and *R. Britannica*, are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of the *R. crispus* and *R. obtusifolius*; and the *R. alpinus* has in some parts of Europe the common name of *mountain rhubarb*. This resemblance of properties is not singular, as the two genera belong to the same natural family. Dock-root is given in powder or decoction. Two ounces of the fresh root bruised, or one ounce of the dried, may be boiled in a pint of water, of which two fluidounces may be given at a dose, and repeated as the stomach will bear it. The root has often been applied externally in the shape of ointment, cataplasm, and decoction, to the various cutaneous eruptions and ulcerations for which its internal use is recommended. The powdered root is recommended as a dentifrice, especially when the gums are spongy. W.

RUTA. U.S. Secondary, Lond., Ed.

Rue odorante, *Fr.*; Garten-Raute, *Germ*; Ruta, *Ital.*; Ruda, *Span.*

RUTA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Rutaceæ.

Gen. Ch. Calyx five-parted. Petals concave. Receptacle surrounded by ten melliferous points. Capsule lobed. Willd.

Ruta graveolens. Willd. *Sp. Plant.* ii. 542; Woodv. *Med. Bot.* p. 487. t. 174. Common rue is a perennial plant, usually two or three feet high, with several shrubby branching stems, which, near the base, are woody and covered with a rough bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are doubly pinnate, glaucous, with obovate, sessile, obscurely crenate, somewhat thick and fleshy leaflets. The flowers are yellow, and disposed in a terminal branched corymb upon subdividing peduncles. The calyx is persistent, with four or five acute segments; the corolla consists of four or five concave petals somewhat sinuate at the margin. The stamens are usually ten, but sometimes only eight in number. The plant is a native of the South of Europe, but cultivated in our gardens. It flowers from June to September. The whole herbaceous part is active; but the leaves are usually employed.

These have a strong disagreeable odour, especially when rubbed. Their taste is bitter, hot, and acrid. In the recent state, and in full vigour, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend

chiefly on a volatile oil, which is very abundant, and is contained in glandular vesicles, apparent over the whole surface of the plant. (See *Oleum Rutæ*.) Besides volatile oil, they contain, according to Mühl, chlorophylle, albumen, an azotized substance, extractive, gum, starch or inulin, malic acid, and lignin. Both alcohol and water extract their active properties.

Medical Properties and Uses. Rue is stimulant and antispasmodic, and like most other substances which excite the circulation, occasionally increases the secretions, especially when they are deficient from debility. It appears to have a tendency to act upon the uterus; in moderate doses proving emmenagogue, and in larger doses producing a degree of irritation in that organ which sometimes determines abortion. Taken in very large quantities, it acts as an acrid narcotic poison. Three cases are recorded by Dr. Hélie in which it was taken by pregnant women, with the effect of producing dangerous symptoms of gastro-intestinal inflammation and cerebral derangement, which continued for several days, but from which the patients ultimately recovered. In each of these cases miscarriage resulted. Great depression and slowness of the pulse attended the narcotic action of the poison. (*Ann. d'Hyg. Pub. et de Med. Lég.* xx. 180.) Rue is sometimes used in hysterical affections, flatulent colic, and amenorrhœa, particularly in the last complaint. It has also been given in worms. The ancients employed it as a condiment, and believed it to possess, besides other valuable properties, that of resisting the action of poisons. Its excitant and irritating properties require that it should be used with caution. The dose of the powder is from fifteen to thirty grains two or three times a day. The medicine is also given in infusion and extract. In one of the cases of poisoning above mentioned, three fresh roots of the size of the finger were taken in the form of decoction.

Off. Prep. Confectio Rutæ, *Lond., Dub.*; Extractum Rutæ, *Dub.*; Oleum Rutæ, *Ed., Dub.* W.

SABADILLA. *U. S., Lond., Ed.*

Cevadilla.

"The seeds of *Veratrum Sabadilla*." *U. S.* "*Helonias officinalis*. *Semina.*" *Lond.* "Fruit of *Veratrum Sabadilla*, *Helonias officinalis*, and probably of other *Melanthaceæ*." *Ed.*

Cévadilla, Fr.; Sabadillsame, Germ.; Cevadilla, Span.

There has been much uncertainty in relation to the botanical origin of cevadilla. For some time after it began to attract attention as the source of veratria, it was generally believed to be derived from the *Veratrum Sabadilla*, which is recognised by the *U. S. Pharmacopœia*. But Schiede, during his travels in Mexico, ascertained that it was, in part at least, collected from a different plant, of the same natural order of *Melanthaceæ*, growing upon the eastern declivity of the Mexican Andes. This was considered by Schlechtendahl as a different species of the same genus *Veratrum*, by Don as a *Helonias*, and by Lindley as belonging to a new genus which he named *Asagræa*. Hence it has been variously denominated *Veratrum officinale*, *Helonias officinalis*, and *Asagræa officinalis*. The London College refers cevadilla to this plant, with Don's title of *Helonias officinalis*; while the Edinburgh College recognises both this, and the *Veratrum Sabadilla*, and admits other plants of the same order as probable sources of the drug. More exact information, however, is wanted, before we can determine its precise origin. It has been adopted in the *Pharmacopœias* solely

on account of its employment in the preparation of veratria. It is brought from Vera Cruz in Mexico.*

The cevadilla seeds usually occur in commerce mixed with the fruit of the plant. This consists of three coalescing capsules or foliicles, which open above, and present the appearance of a single capsule with three cells. It is three or four lines long and a line and a half in thickness, obtuse at the base, light brown or yellowish, smooth, and in each capsule contains one or two seeds. A resemblance existing or supposed between this fruit and that of barley, is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, two or three lines long, wrinkled, slightly winged, black or dark brown on the outside, whitish within, hard, inodorous, and of an exceedingly acid, burning, and durable taste. Cevadilla was found by Pelletier and Caventou to contain a peculiar organic alkali which they named veratria, combined with gallic acid; fatty matter, consisting of olein, stearin, and a peculiar volatile fatty acid denominated *cevadilic* or *sabadillic acid*; wax; yellow colouring matter; gum; lignin; and salts of potassa and of lime with a little silica. From 100 parts of the seeds, separated from their capsules, Meissner obtained 0.58 of veratria. Besides the principles above mentioned, M. Couerbe discovered another organic alkali (*sabadillia*), a resinous substance (*veratrin*), and a resinoid substance which he called *resini-gum of sabadillia*. A peculiar acid was also discovered by Merck, called *veratric acid*, which is in colourless crystals, fusible and volatilizable without decomposition, but slightly soluble in cold water, more soluble in hot water, soluble in alcohol, insoluble in ether, having the properties of reddening litmus paper, and forming soluble salts with the alkalies.

The following process is recommended by M. Couerbe for obtaining veratria. An extract of cevadilla, obtained by treating this substance with boiling alcohol and evaporating the tincture, is to be boiled with water acidulated with sulphuric acid until the liquid ceases to receive colour, or till a mineral alkali introduced into it, no longer occasions any sign of pre-

* Until more definitive information is obtained on the subject, we give in a note a brief description of the two plants above referred to.

Veratrum Sabadilla. Retzius, *Obs.* i. 31; Descourtilz, *Ann. Soc. Linn. Par. A. D.* 1824, 167. See *Veratrum Album*. The leaves of this plant are numerous, ovate oblong, obtuse, with from eight to fourteen ribs, glaucous beneath, and all radical. The flower-stem is erect, simple, and round, rises three or four feet in height, and bears a spreading, simple, or but slightly branched panicle of somewhat nodding flowers, supported upon very short pedicels. The flowers, which are of a blackish purple colour, approximate in twos and threes, the fertile turning at length to one side, and the sterile falling off. The segments of the corolla are ovate lanceolate, and without veins. The capsules occupy only one side of the stem. This plant grows in Mexico and the West Indies, and was cultivated by Descourtilz at San-Domingo, from seeds obtained in Mexico.

Asagraea officinalis. Lindley, *Botan. Reg.*, June, 1839.—*Veratrum officinale*. Schlechtendahl, *Linnaea*, vi. 45.—*Helonias officinalis*. Don, *Ed. New Phil. Journ.*, Octob. 1832, p. 234. The following is the generic character given by Lindley. "Flowers polygamous, racemose, naked. *Perianth* six-partite; segments linear, veinless, almost equal, with a nectariferous excavation at the base, equal to the stamens. *Stamens* alternately shorter; anthers cordate, as if unilocular, after dehiscence, shield-shaped. *Ovaries* three, quite simple, attenuated into an obscure stigma. *Follicles* three, acuminate, papery; seeds scimitar-shaped, corrugated, winged. Bulbous herbs, with grass-like leaves, and small, pale, and densely racemed flowers." The *A. officinalis*, which is the only known species, has linear, acuminate, subcarinate leaves, roughish at the margin, and four feet in length by three lines in breadth, and a round flower-stem, about six feet high, terminating in a very dense, straight, spike-like raceme, eighteen inches long. The flowers are white, with yellow anthers.

precipitation. To the solution of impure sulphate of veratria thus obtained, a solution of potassa or ammonia is to be added, and the resulting precipitate is to be treated with boiling alcohol and animal charcoal. The alcoholic solution, being filtered and evaporated, will yield the veratria sufficiently pure for medical use. A drachm of it, in this state, may be procured from a pound of cevadilla. But besides veratria, M. Couerbe has shown that the principles, called respectively *sabadillia* and *veratrin*, are also contained in this product. These are separated in the following manner. Into the solution of impure sulphate of veratria obtained in the above process, nitric acid is to be introduced by drops. This occasions an abundant precipitate, from which the clear liquor is to be decanted. A weak solution of potassa is then to be added to the liquor, and the precipitate which it produces is to be washed with cold water, and treated with boiling alcohol. The substance obtained by evaporating the alcohol yields the *sabadillia* to boiling water, which deposits it upon cooling; a substance called by M. Couerbe *resini-gum* of *sabadillia*, remaining in solution. If the residue of the substance, treated as just mentioned with boiling water, be submitted to the action of ether, it yields to this liquid the proper *veratria*, which may be obtained entirely pure by the spontaneous evaporation of the ether. The matter remaining undissolved is the resinous substance which M. Couerbe calls *veratrin*.

Veratria, when pure, is white, pulverulent, uncrystallizable, inodorous, extremely acrid, fusible by heat, scarcely soluble in cold water, soluble in a thousand parts of boiling water which it renders sensibly acrid, dissolved freely by alcohol, less so by ether, and capable of neutralizing the acids, with several of which, particularly the sulphuric and muriatic, it forms crystallizable salts. For a further account of veratria, with its effects upon the system, and its remedial applications, see the article *Veratria* in the second part of this work.

Sabadillia is white, crystallizable, insupportably acrid, fusible by heat, readily soluble in hot water, which deposits it upon cooling, very soluble in alcohol, and wholly insoluble in ether. It is capable of saturating the acids. According to Simon, *sabadillia* is a compound of resinate of soda and resinate of veratria.

For practical purposes it is unnecessary to obtain these two principles in a separate state; the impure veratria, procured by the process above described, being the preparation usually employed in medicine. (*Journ. de Pharm.* xix. 527.)

Medical Properties and Uses. Cevadilla is an acrid drastic emetocathartic, operating occasionally with great violence, and in over doses capable of producing fatal effects. It was made known as a medicine in Europe so early as the year 1572; but has never been much employed. It has been chiefly used as an anthelmintic, especially in cases of tænia, in which it has been given in doses varying from five to thirty grains. It has also been given in different nervous affections. It is the principal ingredient of the *pulvis Capucinatorum*, sometimes used in Europe for the destruction of vermin in the hair. It is considered by the natives of Mexico useful in hydrophobia, and was employed by M. Fouilhoux, of Lyons, in a supposed case of that disease, in the dose of about nine grains, with asserted success. Externally applied, it is highly irritating, and is even said to be corrosive. Its chief employment at present is for the preparation of veratria.

SABBATIA. U.S.

American Centaury.

"The herb of *Sabbatia angularis*. U.S.

SABBATIA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianaceæ.

Gen. Ch. Calyx five to twelve-parted. Corolla rotate, five to twelve-parted. Stigmas two, spiral. Anthers at length revolute. Capsule one-celled, two-valved, many-seeded. Nuttall.

Sabbatia angularis. Pursh. *Flor. Am. Sept.* 137; Bigelow, *Am. Med. Bot.* iii. 147; Barton, *Med. Bot.* i. 255.—*Chironia angularis*. Linn. The American centaury is an annual or biennial herbaceous plant, with a fibrous root, and an erect, smooth, four-sided stem, winged at the angles, simple below, sending off opposite axillary branches above, and rising one or two feet in height. The leaves, which vary considerably in length and width, are ovate, entire, acute, nerved, smooth, opposite, and sessile, embracing half the circumference of the stem at their base. The flowers are numerous, growing on the ends of the branches, and forming altogether a large terminal corymb. The calyx is divided into five lanceolate segments, considerably shorter than the corolla. This is deeply five-parted, with obovate segments of a beautiful delicate rose-colour, which is paler and almost white in the middle of their under surface. The anthers are yellow, and after shedding their pollen become revolute. The style, which is bent downward, and is longer than the stamens, terminates in two linear stigmas, which become spirally twisted together.

The plant is widely diffused through the Middle and Southern States, growing in low meadow grounds, and in wet seasons upon uplands, in woods and neglected fields. It flowers in July and August. In its general aspect as well as medical properties, it bears a close resemblance to the *Erythræa*, formerly *Chironia Centaurium*, or European centaury, for which it was mistaken by the earlier settlers. The whole herb is employed, and should be collected when in flower.

All parts of it have a strongly bitter taste, without any admixture of astringency or other peculiar flavour. Both alcohol and water extract its bitterness, together with its medical virtues.

Medical Properties and Uses. American centaury has the tonic properties of the simple bitters, and is very analogous in its action to the other plants belonging to the same natural family. It has long been popularly employed as a prophylactic and remedy in our autumnal intermittent and remittent fevers; and has found much favour with the medical profession in the latter of these complaints. The state of the fever to which it is particularly applicable, is that which exists in the intervals between the paroxysms, when the remission is such as to call for the use of tonics, but is not sufficiently decided to justify a resort to the preparations of Peruvian bark. It is also occasionally useful during the progress of a slow convalescence, by promoting appetite and invigorating the digestive function; and may be employed for the same purpose in dyspepsia and diseases of debility.

The most convenient form for administration is that of infusion. A pint of boiling water poured on an ounce of the herb and allowed to cool, may be given in the dose of two fluidounces, repeated every hour or two during the remission of fevers, and less frequently in chronic affections. The dose of the powder is from thirty grains to a drachm. The decoction, extract, and tincture are also efficient preparations.

SABINA. U.S., Lond., Ed.

Savine.

“The tops of *Juniperus Sabina*.” U.S., Ed. “*Juniperus Sabina*. *Cumina recentia et exsiccata*.” Lond.

Off. Syn. JUNIPERUS SABINA. Folia. Dub.

Sabine, Fr.; Sevenbaum, Germ.; Sabina, Ital., Span.

JUNIPERUS. See JUNIPERUS.

Juniperus Sabina. Willd. *Sp. Plant.* iv. 852; Woodv. *Med. Bot.* p. 10. t. 5. This is an evergreen shrub, rising from three or four feet to fifteen feet in height, with numerous erect, pliant branches, very much subdivided. The bark of the young branches is light green, that of the trunk rough and reddish-brown. The leaves, which completely invest the younger branches, are numerous, small, erect, firm, smooth, pointed, of a dark green colour, glandular in the middle, opposite, and imbricated in four rows. The flowers are male and female on different trees. The fruit is a blackish-purple berry, of an ovoid shape, marked with tubercles, the remains of the calyx and petals, and containing three seeds.

The savine is a native of the South of Europe and the Levant. It is said also to grow wild in the neighbourhood of our North western lakes. The ends of the branches, and the leaves by which they are invested, are collected for medical use in the spring. When dried they fade very much in colour.

There is reason to believe that the *Juniperus Virginiana*, or common red cedar, is sometimes substituted in the shops for the savine, to which it bears so close a resemblance as to be with difficulty distinguished. The two species, however, differ in their taste and smell. In the *J. Virginiana*, moreover, the leaves are sometimes ternate.

The tops and leaves of savine have a strong, heavy, disagreeable odour, and a bitter, acrid taste. These properties, which are less striking in the dried than in the recent leaves, are owing to a volatile oil, which is obtained by distillation with water. (See *Oleum Sabinæ*.) The leaves impart their virtues to alcohol and water. From an imperfect analysis by Mr. C. H. Needles, they appear to contain, volatile oil, gum, tannin or gallic acid, resin, chlorophylle, fixed oil, bitter extractive, lime, and salts of potassa. (*Am. Journ. of Pharm.* xiii. 15.)

Medical Properties and Uses. Savine is highly stimulant, increasing most of the secretions, especially those of the skin and uterus, to the latter of which organs it is supposed to have a peculiar direction. It has been much used in amenorrhœa, and occasionally as a remedy for worms. Dr. Chapman strongly recommends it in chronic rheumatism. In over doses it is capable of producing dangerous gastro-intestinal inflammation, and should therefore be used with caution. In no case should it be given when much general or local excitement exists. In pregnancy it should always be avoided. It is most conveniently administered in the form of powder, of which the dose is from five to fifteen grains, repeated three or four times a day.

As an external irritant it is very useful, in the form of cerate, for maintaining a discharge from blistered surfaces; but as the preparation sold in this country under the name of savine ointment is often deficient in power, either from the age of the drug or the substitution of red cedar, it has in some measure fallen into disrepute. (See *Ceratum Sabinæ*.) In the state

of powder or infusion, savine is used in Europe as an application to warts, indolent, carious, and gangrenous ulcers, psora, and tinea capitis; and the expressed juice of the fresh leaves, diluted with water, is sometimes applied to similar purposes.

The saccharine principles distinguished by the chemist are cane sugar, or sugar properly so called, derived from the sugar cane, the beet, and the sugar maple; glucose or grape sugar, of which the crystallizable sugar of honey, starch sugar, and diabetic sugar, if not identical with it, are varieties; uncrySTALLIZABLE sugar, called by Soubeiran *chulariose* (from *χυλαριον*, syrup); lactic or sugar of milk; sugar of ergot, improperly called mushroom sugar; mannite; and glycerin. All these saccharine principles are susceptible of the vinous fermentation, except mannite and glycerin. *Glucose*, or *grape sugar*, is found in nearly all fruits. Its taste is less sweet than that of cane sugar. It has the sp. gr. of 1.386. It is less soluble in water, and much more soluble in alcohol than cane sugar. Obtained from a concentrated aqueous solution, it forms crystalline grains. Strong mineral acids hardly act on grape sugar, but destroy cane sugar with facility. On the other hand, grape sugar is destroyed by alkalies, with several of which cane sugar forms definite compounds. Dissolved in water and subjected to prolonged ebullition, it undergoes very little alteration. Grape sugar is the immediate material which undergoes the vinous fermentation; for although other sugars will undergo this process, there is good reason to believe that they will not ferment without being first converted into grape sugar. This has been shown to be the fact in the case of cane sugar by H. Rose. This sugar requires eight times as much ferment, to cause it to undergo the vinous fermentation, as is necessary to produce the same change in grape sugar; and

if the fermentation in cane sugar be arrested before it is completed, part of the sugar will be found to be converted into grape sugar. (*Journ. de Pharm.* xxvii. 681.) Soubeiran admits the occurrence of a preliminary change in cane sugar before fermentation, but considers it as undecided whether this change is into grape or uncrystallizable sugar. *Uncrystallizable sugar* exists in honey and in the juice of fruits, and is generated from cane sugar by solution in water or weak acids, and long boiling. Hence it is present in molasses. The view of Liebig that the uncrystallizable sugar of fruits, and that generated by weak acids, is really a combination of ordinary sugar and acid, has been disproved by Soubeiran, who obtained it exempt from acid, and, therefore, considers it a distinct kind of sugar. (*Journ. de Pharm.* for Jan. 1842.) *Lactin* is a white, crystalline, semitransparent substance, obtained from the whey of milk, permanent in the air, soluble in water, but insoluble in alcohol and ether. By the action of nitric acid, it is converted into mucic (sacclactic) acid. *Mannite* is described under manna, and *glycerin* under soap. (See *Manna* and *Sapo*.) Cane sugar is manufactured extensively in France from the beet, and in considerable quantities in the north-western parts of the United States, as well as in Canada, from the sap of the sugar maple (*Acer Saccharinum*). But the supply of sugar from these sources is insignificant when compared with that obtained from the sugar cane itself, which is extensively cultivated in the East and West Indies, Brazil, and some of our Southern States, particularly Louisiana, for the purpose of being manufactured into sugar. This plant is the *Saccharum officinarum* of botanists, and is the source of the officinal sugars of the Pharmacopœias.

SACCHARUM. *Sex. Syst.* Triandria Digynia.—*Nat. Ord.* Graminaceæ.

Gen. Ch. Calyx two-valved, involucred, with long down. Corolla two-valved. Willd.

Saccharum officinarum. Willd. *Sp. Plant.* i. 321; *Phil. Trans.* lxi. 207. The sugar cane is an herbaceous plant, possessing a jointed, succulent root, from which arise several shining, jointed, solid stems, from an inch to two inches in diameter, and from six to twelve feet high, and containing a white and juicy pith. The colour of the stem is yellow, greenish-yellow, purple, or striped. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base, are three or four feet long, and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green colour inclining to yellow. The flowers are pinkish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant has a general resemblance to the Indian corn. Four varieties are mentioned; 1. the *common*, with a yellow stem; 2. the *purple*, with a purple stem and richer juice; 3. the *gigantic*, with a very large, light-coloured stem; and 4. the *Otaheitan*, which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh, and is distinguished by its greater height, the longer intervals between its joints, and by the greater length of the hairs which surround the flowers.

The sugar cane is a native of the tropical regions of both the old and new continents. It is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be renewed. At the end of a year the plant generally flowers, and in four or five months afterwards the canes are completely ripe, at which time they have a yellowish colour, and contain a sweet viscid juice. The quantity of sugar which they yield is variable. Accord-

ing to Avequin, of New Orleans, the proportion of cane sugar in the recent stalk is about 10 per cent., of uncrystallizable sugar from $3\frac{1}{2}$ to 4 per cent.

Preparation and Purification. The canes being ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between iron rollers in a kind of mill. The juice is of a pale-greenish colour, sweet taste, and balsamic odour, and has a sp. gr. varying from 1.033 to 1.106. As it runs out it is received in suitable vessels, and being quickly removed, is immediately mixed with lime in the proportion of one part to eight hundred of the juice, and heated in a boiler to 140° . The gluten and albumen rise to the top, and form a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by ebullition, the froth being carefully skimmed off as it forms. When sufficiently concentrated, it is transferred to shallow vessels called coolers, from which, before it is cool, it is drawn off into wooden vessels, with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours, the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup is allowed to drain off from the sugar, which in this state is granular, of a yellowish colour, and moist. It is next dried in the sun, and being introduced into hogsheads, forms the *brown sugar* of commerce. The syrup, by a new evaporation, furnishes an additional portion of sugar; and the portion which finally remains, incapable of yielding more sugar, is the liquid called *molasses*. Eight pounds of the juice yield, on an average, one pound of brown sugar. In the process of extraction, it is important that the juice should be concentrated by a moderate heat, which prevents the cane sugar from being converted into uncrystallizable sugar, and, therefore, lessens the amount of the molasses. Sometimes the brown sugar undergoes an additional preparation, consisting in boiling it with lime-water, and, after sufficient concentration, allowing the syrup to crystallize in large inverted conical vessels, pierced at the apex and plugged. The surface of the crystalline mass being covered with a thin mixture of clay and water, the plug is removed, and the water from the clay, penetrating the mass, removes the coloured syrup, which flows out at the hole. The sugar, as thus prepared, approaches to the white state, and constitutes the clayed sugar of commerce, usually called in this country *Havana sugar*. It is still, however, far from being pure.

The refining of brown sugar forms a distinct branch of business, and the methods pursued have undergone many changes and improvements. By the original process, the sugar was boiled with lime-water, and clarified by heating it with bullocks' blood. The clarified syrup was then strained through a woollen cloth, whereby it was rendered limpid. It was next transferred to a boiler, where it was subjected to ebullition, until it was brought to a proper concentration, when it was allowed to cool in conical moulds, and to drain for the separation of the molasses. This last boiling required to be continued so long, that the action of the fire and air frequently decomposed the sugar to such an extent, as to cause a loss of twenty-five per cent. in molasses. This disadvantage has led to the abandonment of prolonged boiling; and now, for the most part, the sugar refiners boil the syrup in shallow boilers, which are suspended in such a way as to admit of their being emptied with the greatest quickness, without putting out the fire. By this arrangement, ten minutes are a sufficient time for boiling, and thus any considerable decomposition of the sugar is avoided.

The process of refining has been still further improved by Messrs. Philip

Taylor and Howard. The former introduced the improvement of heating the syrup with great rapidity by means of steam, made to pass through a series of tubes traversing the boiler; and the latter devised the plan of causing the syrup to boil under a diminished pressure, created by a suction pump, set in motion by a steam engine, while it was heated by steam, circulating round the boiler. In this way, the syrup was made to boil at a lower temperature, and with a diminished contact with the air; and the loss of the cane sugar, by conversion into uncrystallizable sugar, was in a great measure avoided.

After the syrup is sufficiently concentrated by any one of these methods, it is transferred to coolers, where it is agitated to cause it to granulate. In this state it is poured into unglazed earthenware moulds of a conical shape, with a hole in the apex, which is stopped with a paper plug. The moulds are placed, with the apex downwards, above stone-ware pots, intended to receive the uncrystallizable syrup. When the mass has completely concreted, the moulds are unstopped, to allow the coloured syrup to drain off. To remove the remains of this syrup, the operation called *claying* is performed. This consists in removing from the base of the loaf, a layer of the sugar, about an inch thick, and replacing it with pure sugar in powder, which is covered with a mixture of pipe clay and water, of about the consistence of cream. The water gradually leaves the clay, dissolves the pure sugar, and percolates the mass as a pure syrup, removing in its progress the coloured syrup. Sometimes the purification is performed without the use of clay, by allowing a saturated solution of pure sugar to percolate the loaf. When all the coloured syrup is removed, the loaf is taken out of the mould and placed in stoves to dry. It now constitutes *white* or *purified sugar*. The syrup which drains from the loaves contains a considerable quantity of cane sugar, and is used in subsequent operations. The syrups of lowest quality are employed in forming inferior white sugar, from which a syrup finally drains, containing so little cane sugar as not to repay the expense of extracting it. This constitutes *sugar house molasses*. Good brown sugar, in the process of refining, yields about 70 per cent. of white sugar.

After the clarification by bullocks' blood, the syrup is decolorized by allowing it to filter through a bed of coarse-grained animal charcoal, nearly three feet thick.

Of the several forms of sugar above indicated, as resulting from the various steps in its preparation from the cane, three only, *white* and *brown sugar*, and *molasses*, are officinal in the British and United States Pharmacopœias, and these are designated by the Latin names placed at the head of this article. The United States Pharmacopœia recognises refined sugar only, giving it the name of *Saccharum*; the uses of brown sugar and molasses being replaced by the employment of a prepared syrup of known strength. (See *Syrupus*.) The London College also recognises refined sugar under the name of *Saccharum*; but in the last edition of their Pharmacopœia (1836) they have omitted brown sugar, and inserted molasses. The Edinburgh and Dublin Colleges, besides recognising refined sugar, also admit brown sugar and molasses.

Commercial History. Sugar has been known from the earliest ages, and was originally obtained from Asia. About the period of the Crusades, the Venetians brought it to Europe; but at that time it was so scarce as to be used exclusively as a medicine. Upon the discovery of the Cape of Good-Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Subsequently, the cultivation of the cane was extended to Arabia, Egypt, Sicily, Spain, and the Canaries,

and finally, upon the discovery of the new world, to America, where it was pursued with the greatest success, and continues to be so up to the present day. After this time, sugar became comparatively so cheap and abundant, that, from being viewed as a medicine and costly luxury, it came into almost universal use among civilized nations as an article of food. In America it is produced most abundantly in the West Indies, which supply the greater part of the consumption of Europe, little comparatively being taken thither from the Brazils or the East Indies. The consumption of the United States is more than half supplied by Louisiana and some of the neighbouring states. Within a few years, our planters have introduced into Louisiana the variety of cane called the Otaheite cane, which is hardier and more productive than the common cane, and better suited to the climate of our Southern States.

Properties. Sugar, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosphorescent by friction, and of the sp. gr. 1.6. It dissolves readily in half its weight of cold water, and to almost an unlimited extent in boiling water. The solution, when thick and ropy, is called *syrup*. When a concentrated syrup is gently heated, and spirit added to it, the liquid, on cooling, forms white semi-transparent crystals of hydrated sugar, having the shape of oblique four-sided prisms, and called *sugar-candy*. Sugar is nearly insoluble in absolute alcohol, but dissolves in four times its weight of boiling alcohol of the sp. gr. 0.83. When heated to 365° , it melts into a viscid, colourless liquid, which, on being suddenly cooled, forms a transparent amorphous mass, called *barley sugar*. At a higher temperature (between 400° and 420°) it loses two eqs. of water, and is converted into a black porous mass, having a high lustre like anthracite, called *caramel*. At a still higher heat, it yields combustible gases, carbonic acid, empyreumatic oil, and acetic acid, and there remains one-fourth of its weight of charcoal, which burns without residue. Sugar renders the fixed and volatile oils to a certain extent miscible with water, and forms with the latter an imperfect combination, called in pharmacy *oleo-saccharum*. When in solution, it is not precipitated by subacetate of lead, a negative property by taking advantage of which it may be separated from most other organic principles.

Action of Acids and Alkalies, &c. The mineral acids act differently on cane sugar, according as they are concentrated or dilute. Strong nitric acid, with the assistance of heat, converts it into oxalic acid. (See *Oxalic Acid*, in the Appendix.) The same acid, when weak, converts it into *saccharic acid*, confounded by Scheele with malic acid. Concentrated muriatic or sulphuric acid chars it. Diluted muriatic acid, when boiled with cane sugar, converts it into a solid, brown, gelatinous mass. Weak sulphuric acid, by a prolonged action at a high temperature, converts cane sugar, first into uncrystallizable sugar, afterwards into grape sugar, and finally into two substances, analogous to ulmin and ulmic acid, called *sacchulmin* and *sacchulmic acid*. Vegetable acids are supposed to act in a similar way. If the boiling be prolonged for several days in open vessels, oxygen is absorbed, and, besides these two substances, formic acid is formed. Soubeiran admits the change of the uncrystallizable into grape sugar, but attributes it to a molecular transformation of the sugar, independently of the action of the acid; as, according to his observations, the conversion takes place only after rest. In confirmation of his views, this chemist states that he found the same changes to be produced by boiling sugar with water alone.

Cane sugar unites with the alkalies and some of the alkaline earths, forming combinations which render the sugar less liable to change. It also

unites with protoxide of lead. Boiled for a long time with aqueous solutions of potassa, lime, or baryta, the liquid becomes brown, formic acid is produced, and two new acids are generated, discovered by Peligot, one brown or black and insoluble in water, called *melassic acid*, the other, colourless and very soluble, named *glucic acid*. It is supposed that the cane sugar is converted into grape sugar before these acids are formed.

The account above given of the action of acids and alkalies on sugar explains the way in which lime acts in the manufacture and refining of sugar. The acids, naturally existing in the saccharine juice, have the effect of converting the cane sugar into uncrystallizable sugar, by which a loss of the former is sustained. The use of lime, by neutralizing these acids, prevents this result. The changes in the sugar which precede fermentation point to the necessity of operating before this process sets in; and hence the advantage of grinding the canes immediately after they are cut, and boiling the juice with the least possible delay.

From these general remarks on the different varieties of sugar, and the action of chemical agents, we pass to the description of the several forms of officinal sugar.

Purified or white sugar, as obtained on a large scale, is in concrete, somewhat porous masses, called loaves, consisting of an aggregate of small crystalline grains. When carefully refined, it is brittle and pulverulent, perfectly white, inodorous, and possessed of the pure saccharine taste.

Unpurified or brown sugar is in the form of a coarse powder, more or less moist and sticky, consisting of shining crystalline grains, intermixed with lumps, having an orange-yellow colour, more or less deep, a sweet, cloying taste, and a heavy peculiar smell. It varies very much in quality. The best sort is nearly dry, in large sparkling grains of a clear yellow colour, and possesses much less smell than the inferior kinds. It consists of cane sugar, associated with variable quantities of gummy and colouring matter, and a small proportion of lime and tannic acid. By keeping, it becomes soft and gummy, and weaker in saccharine matter, a change attributed to the lime.

Molasses is of two kinds, the West India and sugar house. *West India molasses* is a black ropy liquid, of a peculiar odour, and sweet empyreumatic taste. When mixed with water and the skimmings of the vessels used in the manufacture of sugar, it forms a liquor, which, when fermented and distilled, yields rum. *Sugar house molasses* has the same general appearance as the West India. It is, however, thicker, and has a different flavour. Its sp. gr. is about 1.4, and it contains about 75 per cent. of solid matter. It is the officinal molasses of the British Colleges. Both kinds of molasses consist of uncrystallizable sugar, more or less cane sugar, which has escaped separation in the process of manufacture or refining, and gummy and colouring matter.

Composition. The following formulas express the composition of the different varieties of sugar, as far as known. Cane sugar, $C_{12}H_{11}O_{11}$. Cane sugar, as it exists in combination with two eqs. of protoxide of lead (caramel? anhydrous sugar?), $C_{12}H_9O_9$. Grape sugar, $C_{12}H_{13}O_{11}$. Grape sugar, heated to 212° , $C_{12}H_{12}O_{12}$. Lactin or sugar of milk, $C_{24}H_{24}O_{24}$. Uncrystallizable sugar has not been analyzed. The theory of the conversion of grape sugar, during the vinous fermentation, into carbonic acid and alcohol, has been explained under another head. (See *Alcohol*.)

Med. and Pharm. Uses, &c. The uses of sugar as an aliment and condiment are numerous. It is nutritious, but, judging from the results of the experiments of Magendie, not capable of supporting life when taken exclu-

sively as aliment, on account of the absence of nitrogen in its composition. It is a powerful antiseptic, and is beginning to be used for preserving meat and fish; for which purpose it possesses the advantage of acting in a much less quantity than is requisite of common salt, and of not altering the taste, nor impairing the nutritious qualities of the aliment.

The medical properties of *sugar* are those of a demulcent, and as such it is much used in catarrhal affections, attended with irritation of the larynx and fauces, in the form of candy, syrup, &c. In pharmacy it is employed to render oils miscible with water, to cover the taste of medicines, to give them consistency, to preserve them from change, and to protect from oxidation certain ferruginous preparations. Accordingly it enters into the composition of several infusions and mixtures, and of nearly all the syrups, confections, and troches. *Brown sugar* is used in the Dublin compound pills of iron, and in the Dublin and Edinburgh infusion of senna with tamarinds; and *molasses*, in preparing the London compound pills of iron, the London and Dublin compound pills of chloride of mercury, the Edinburgh syrup of senna, and the Dublin compound pills of colocynth, and of galbanum, and electuary of senna. Molasses is well fitted for forming pills, preserving them soft and free from mouldiness, on account of its retentiveness of moisture and its antiseptic qualities. In the United States Pharmacopœia brown sugar and molasses are not officinal, their place being usually supplied by syrup.

Off. Prep. of Saccharum. Syrupus, U. S., Lond., Ed., Dub. B.

SAGAPENUM. Lond., Dub.

Sagapenum.

“*Ferulæ species incerta. Gummi-resina.*” Lond.

Sagapenum, Fr.; Sagapen, Germ.; Sagapeno, Ital., Span.; Sugbeenuj, Arab.

All that is known in relation to the source of this gum-resin, is that it is the concrete juice of a plant, probably belonging to the family of the Umbelliferæ, growing in Persia. The plant is conjectured to be a species of *Ferula*, and Willdenow supposes it to be the *F. Persica*, but without sufficient evidence. The drug is brought from Alexandria, Smyrna, and other ports of the Levant.

It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow colour externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alliacious odour, less disagreeable than that of assafetida, and a hot nauseous bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil; and the water is strongly impregnated with its flavour. According to Pelletier, it contains, in 100 parts, 54·26 of resin, 31·94 of gum, 1·0 of bassorin, 0·60 of a peculiar substance, 0·40 of acidulous malate of lime, and 11·80 of volatile oil including loss. Brandes found 3·73 per cent. of volatile oil. This is of a pale yellow colour, very fluid, lighter than water, and of a very disagreeable alliacious odour.

Medical Properties and Uses. Sagapenum is a moderate stimulant, simi-

lar to assafetida in its properties, but much inferior, and usually considered as holding a middle station between that gum-resin and galbanum. It has been given as an emmenagogue and antispasmodic in amenorrhœa, hysteria, chlorosis, &c., but is now seldom used. The ancients were acquainted with it; and Dioscorides speaks of it as being derived from Media. The dose is from ten to thirty grains, and may be administered in pill or emulsion. Sagapenum is also considered discutient, and has been occasionally applied externally, in the form of plaster, to indolent tumours.

SAGO. *U.S., Lond., Ed.*

Sago.

“The prepared fecula of the pith of *Sagus Rumphii*.” *U.S.* “*Sagus Rumphii. Medullæ Fæcula.*” *Lond.* “Farina from the interior of the trunk of various *Palmaceæ* and species of *Cycas*.” *Ed.*

Sagu, Fr.; Sago, Germ., Ital.; Sagu, Span.

Numerous trees inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith which is applied to the purposes of nutriment by the natives. Such are the *Sagus Rumphii*, *Sagus lævis*, *Sagus Ruffia*, *Saguerus Rumphii*, and *Phœnix farinifera*, belonging to the family of *Palms*; and the *Cycas circinalis*, *Cycas revoluta*, and *Zamia lanuginosa*, belonging to the *Cycadaceæ*. Of these the *Sagus Rumphii*, *Sagus lævis*, and *Saguerus Rumphii* probably contribute to furnish the sago of commerce. Crawford, in his History of the Indian Archipelago, states that it is derived exclusively from the *Metroxylon Sagu*, identical with the *Sagus Rumphii*; but Roxburgh ascribes the granulated Sago to *S. lævis*, and one of the finest kinds is said by Dr. Hamilton to be produced by the *Saguerus Rumphii* of Roxburgh. The farinaceous product of the different species of *Cycas*, sometimes called *Japan Sago*, does not enter into general commerce.

SAGUS. *Sex. Syst.* Monœcia Hexandria.—*Nat. Ord.* Palmaceæ.

Gen. Ch. Common spathe one-valved. *Spadix* branched. **MALE.** *Calyx* three-leaved. *Corolla* none. *Filaments* dilated. **FEMALE.** *Calyx* three-leaved, with two of the leaflets bifid. *Corolla* none. *Style* very short. *Stigma* simple. *Nut* tessellated-imbricated, one-seeded. *Willd.*

Sagus Rumphii. *Willd. Sp. Plant.* iv. 404; Loudon's *Encyc. of Plants*, p. 789. The *Sago palm* is one of the smallest trees of the family to which it belongs. Its extreme height seldom exceeds thirty feet. The trunk is proportionably very thick, quite erect, cylindrical, covered with the remains of the old leafstalks, and surrounded by a beautiful crown of foliage, consisting of numerous, very large, pinnate leaves, extending in every direction from the summit, and curving gracefully downwards. From the basis of the leaves proceed long, divided and subdivided flower and fruit-bearing spadices, the branches of which are smooth. The fruit is a roundish nut, covered with a checkered imbricated coat, and containing a single seed.

The tree is a native of the East India islands, growing in the Peninsula of Malacca, Sumatra, Borneo, Celebes, the Moluccas, and a part of New Guinea. It flourishes best in low and moist situations. Before attaining maturity, the stem consists of a shell usually about two inches thick, filled with an enormous volume of spongy medullary matter like that of elder. This is gradually absorbed after the appearance of fruit, and the stem ulti-

mately becomes hollow. The greatest age of the tree is not more than thirty years. At the proper period of its growth, when the medullary matter is fully developed, and has not yet begun to diminish, the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough, having a sieve at the end. The water loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off; and the farina which is left may be dried into a kind of meal, or moulded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly lustre. Malcolm states that it is also refined in large quantities at Singapore. In this state it is called *pearl sago*, and is in great repute. It is said that not less than five or six hundred pounds of sago are procured from a single tree. (*Crawford*.)

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin's head, hard, whitish, or of a light brown colour, in some instances translucent, inodorous, and with little taste. It may be rendered perfectly white by a solution of chloride of lime.

Common sago is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty looking powder.

Sago meal is imported into England from the East Indies; but we have met with none in the markets of this country. It is in the form of a fine amylaceous powder, of a whitish colour, with a yellowish or reddish tint, and of a faint but somewhat musty odour.

Common sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to heat used in its preparation. Chemically considered, it has the characters of starch. Under the microscope, the granules of sago meal appear oval or ovate, and often truncated, so as to be more or less mullar-shaped. Many of them are broken, and in most, the surface is irregular or tuberculated. They exhibit upon their surface concentric rings, which, however, are much less distinct than in potato starch. The hilum is circular when perfect, and cracks either with a single slit, or a cross, or in a stellate manner. The granules of pearl sago are of the same form, but are all ruptured, and exhibit only indistinct traces of the annular lines, having been altered in the process employed in preparing them. Those of the common sago are very similar to the particles of sago meal, except that they are perhaps rather less regular and more broken. (*Pereira*.)

Potato starch is sometimes prepared in Europe so as to resemble bleached pearl sago, for which it is sold. But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken and more distinctly marked with the annular rugæ than those of sago; and the circular hilum often cracks with two slightly diverging slits.

Sago is used exclusively as an article of diet, having no medicinal qualities which adapt it to the treatment of disease. Being nutritive, easily digestible,

and wholly destitute of irritating properties, it is frequently employed in febrile cases, and in convalescence from acute disorders, in the place of richer and less innocent food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining; as it might offend a delicate stomach. A tablespoonful to the pint of water is sufficient for ordinary purposes. The solution may be seasoned with sugar and nutmeg, or with other spices, and with wine, where these are not contra-indicated.

SALIX. U.S. Secondary.

Willow.

“The bark of *Salix alba*.” U. S.

Off. Syn. SALICIS CORTEX. Bark of *Salix Caprea*. *Ed.*; SALIX ALBA. SALIX FRAGILIS. SALIX CAPREA. Cortex. *Dub.*

Ecorce de saule, *Fr.*; Weidenrinde, *Germ.*; Corteccia di salcio, *Ital.*; Corteza de sauce, *Span.*

SALIX. *Sex. Syst.* Diœcia Diandria.—*Nat. Ord.* Salicaceæ.

Gen. Ch. MALE. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Glands* of the base nectariferous. FEMALE. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Style* two-cleft. *Capsule* one-celled, two-valved. *Seeds* downy. *Willd.*

This is a very extensive genus, comprising, according to Nuttall, not less than one hundred and thirty species, which, with very few exceptions, are natives of Europe and of the northern and temperate parts of North America. Though most of them are probably possessed of similar medical properties, only three have been admitted to the rank of officinal plants by the British Colleges; viz. *S. alba*, *S. caprea*, and *S. fragilis*. Of these species, the *Salix alba* is the only one which has been introduced into this country, and is expressly recognised in the last edition of our Pharmacopœia. The *S. Russelliana*, which has been introduced from Europe, is said by Sir James Smith to be the most valuable species. The *S. purpurea*, which is a European species, is said by Lindley to be the most bitter, and the *S. pentandra* is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign; but they have not been sufficiently tried in regular practice to admit of a positive decision in relation to them. The younger Michaux speaks of the *S. nigra* or *black willow*, as affording in its root a strong bitter, used in the country as a preventive and cure of intermittents. In consequence of the pliability of the young branches or twigs, the willow is admirably adapted for the manufacture of baskets and other kinds of wicker-work, and several species, as well native as introduced, are employed for this purpose in the United States. The *S. Babylonica* or weeping willow is a favourite ornamental tree. The degree of bitterness in the bark is probably the best criterion of the value of the different species.

Salix alba. Willd. *Sp. Plant.* iv. 710; Smith, *Flor. Brit.* 1071. The common European or white willow is a tree twenty-five or thirty feet in height, with numerous round spreading branches, the younger of which are silky. The bark of the trunk is cracked and brown, that of the smaller branches smooth and greenish. The leaves are alternate, upon short petioles, lanceolate, pointed, acutely serrate with the lower serratures glandu-

lar, pubescent on both sides, and silky beneath. There are no stipules. The flowers appear at the same time with the leaves. The *amenta* are terminal, cylindrical, and elongated, with elliptical, lanceolate, brown, pubescent scales. The stamens are two in number, yellow, and somewhat longer than the scales; the style is short; the stigmas two-parted and thick. The capsule is nearly sessile, ovate, and smooth.

The white willow has been introduced into this country from Europe, and is now very common. It flowers in April and May; and the bark is easily separable throughout the summer.

That obtained from the branches rolls up when dried into the form of a quill, has a brown epidermis, is flexible, fibrous, and of difficult pulverization. Willow bark has a feebly aromatic odour, and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found among its ingredients, tannin, resin, a bitter yellow colouring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. A crystalline principle has also been obtained from it, which, having the medical virtues of the willow, has received the name of *salicin*. When pure, it is in white, shining, slender crystals, inodorous, but very bitter, with the peculiar flavour of the bark. It is soluble in cold water, much more so in boiling water, soluble in alcohol, and insoluble in ether and the oil of turpentine. It neutralizes neither acids nor salifiable bases; and is not precipitated by any reagent. Concentrated sulphuric acid decomposes it, receiving from it an intense and permanent bright red colour, and producing a new compound called *rutulin*. Muriatic and dilute sulphuric acid convert it into grape-sugar, and a white, tasteless, insoluble powder named *saliretin*. Distilled with bichromate of potassa and sulphuric acid, it yields, among other products, a volatile oleaginous fluid, identical with one of the components of oil of spiræa, and from its acid properties, denominated *saliculous acid*. This is considered by Dumas as consisting of a peculiar compound radical called *salicule* and hydrogen. The formula of salicin is $C_{42}H_{29}O_{22}$. (*Turner's Chemistry*.) The honour of its discovery is claimed by Buchner of Germany, and Fontana and Rigatelli of Italy; but M. Leroux of France deserves the credit of having first accurately investigated its properties. Braconnot procured it by adding subacetate of lead to a decoction of the bark, precipitating the excess of lead by sulphuric acid, evaporating the colourless liquid which remains, adding near the end of the process a little animal charcoal previously washed, and filtering the liquor while hot. Upon cooling it deposits the salicin in a crystalline form. (*Journ. de Chimie Medicale, Janv. 1831.*) The following is the process of Merck. A boiling concentrated decoction of the bark is treated with litharge until it becomes nearly colourless. Gum, tannin, and extractive matter, which would impede the crystallization of the salicin, are thus removed from the liquid, while a portion of the oxide is dissolved in union probably with the salicin. To separate this portion of oxide, sulphuric acid is first added and then sulphuret of barium, and the liquor is filtered and evaporated. Salicin is deposited, and may be purified by repeated solution and crystallization. (*Turner's Chemistry*.) Erdmann has given another process. Sixteen ounces of the bark are macerated for twenty-four hours in four quarts of water mixed with two ounces of lime, and the whole is then boiled for half an hour. The process is repeated with the residue. The decoctions having been mixed, and allowed to become clear by subsidence, the liquor is poured off, concentrated to a quart, then digested with

eight ounces of ivory-black, filtered, and evaporated to dryness. The extract is exhausted by spirit containing 28 per cent. of alcohol, and the tincture evaporated so that the salicin may crystallize. This is purified by again dissolving, treating with ivory-black, and crystallizing. (*Christison's Dispensatory*.) Merck obtained 251 grains from 16 ounces of the bark and young twigs of *Salix helix*, and Erdmann 300 grains from the same quantity of the bark of *Salix pentandra*. It may, in all probability, be obtained from any of the willow barks which have a bitter taste. Braconnot procured it also from various species of *Populus*, particularly the *P. tremula* or European aspen.

Medical Properties and Uses. The bark of the willow is tonic and astringent, and has been employed as a substitute for Peruvian bark, particularly in intermittent fever. It has attracted much attention from the asserted efficacy of salicin in the cure of this complaint. There seems to be no room to doubt, from the testimony of numerous practitioners in France, Italy, and Germany, that this principle has the property of arresting intermittents; though the ascription to it of equal efficacy with the sulphate of quinia was certainly premature. The bark may be employed in substance or decoction, in the same doses and with the same mode of preparation as cinchona. The dose of salicin is from two to eight grains, to be so repeated, that from twenty to forty grains may be taken daily, or in the interval between the paroxysms of an intermittent. Magendie has seen fevers cut short in one day by three doses of six grains each. The decoction of willow has been found beneficial as an external application in foul and indolent ulcers.

W.

SALVIA. U.S. Secondary.

Sage.

“The leaves of *Salvia officinalis*.” U.S.

Sauge, Fr.; Salbey, Germ.; *Salvia*, Ital., Span.

SALVIA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatae.

Gen. Ch. Corolla unequal. Filaments affixed transversely to a pedicel. Willd.

Salvia officinalis. Willd. *Sp. Plant.* i. 129; Woodv. *Med. Bot.* p. 352. t. 127. The common garden sage is a perennial plant, about two feet high, with a quadrangular, pubescent, branching, shrubby stem, furnished with opposite, petiolate, ovate lanceolate, crenulate, wrinkled leaves, of a grayish-green colour, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple; and are disposed on long terminal spikes in distant whorls, each composed of few flowers, and accompanied with ovate, acute, deciduous bractes. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle.

Sage grows spontaneously in the South of Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and colour of their flowers, but all possessed of the same medical properties. The flowering period is in June, at which time the plant should be cut and dried in a shady place. The leaves are the officinal portion.

Both these and the flowering summits have a strong, fragrant odour, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water, and contains a considerable proportion of camphor. Sulphate of iron strikes a black colour with their infusion.

Medical Properties and Uses. Sage unites a slight degree of tonic power and astringency with the properties common to the aromatics. By the ancients it was very highly esteemed; but it is at present little used internally, except as a condiment. In the state of infusion it may be given in debilitated conditions of the stomach attended with flatulence, and is said to have been useful in checking the exhausting sweats of hectic fever. But its most useful application is as a gargle in inflammation of the throat and relaxation of the uvula. For this purpose it is usually employed in infusion, with honey and alum, or vinegar. From twenty to thirty grains of the powdered leaves may be given for a dose. The infusion is prepared by macerating an ounce of the leaves in a pint of boiling water, of which two fluidounces may be administered at once. When intended to be used merely as a pleasant drink in febrile complaints, or to allay nausea, the maceration should continue but a very short time, so that all the bitterness of the leaves may not be extracted.

Two other species of *Salvia*—the *S. pratensis* and *S. Sclarea*—are ranked among the officinal plants in Europe. The latter, which is commonly called *clarry*, has been introduced into our gardens. Their medical properties are essentially the same as those of the common sage; but they are less agreeable, and are not much used. In Europe, the leaves of the *S. Sclarea* are said to be introduced into wine in order to impart to it a muscadell taste.

W.

SAMBUCUS. U.S. Secondary, Lond., Ed.

Elder Flowers.

“The flowers of *Sambucus Canadensis*.” U.S. “*Sambucus nigra*. Flores.” Lond. “Flowers of *Sambucus nigra*.” Ed.

Off. Syn. SAMBUCUS NIGRA. Flores. Baccæ. Cortex interior. Dub. Sureau, Fr.; Hollunder, Germ.; Sambuco, Ital.; Sauco, Span.

SAMBUCUS. *Sex. Syst.* Pentandria Trigynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. Calyx five-parted. Corolla five-cleft. Berry three-seeded. Willd.

Sambucus Canadensis. Willd. *Sp. Plant.* i. 1494. Our indigenous common elder is a shrub from six to ten feet high, with a branching stem, which is covered with a rough gray bark, and contains a large spongy pith. The small branches and the leafstalks are very smooth. The leaves are opposite, pinnate, sometimes bipinnate, and composed usually of three or four pairs of oblong oval, acuminate, smooth, shining, deep-green leaflets, the midribs of which are somewhat pubescent. The flowers are small, white, and disposed in loose cymes, having about five divisions. The berries are small, globular, and when ripe of a deep purple colour.

The shrub grows in low moist grounds, along fences, and on the borders of small streams, in all parts of the United States, from Canada to Carolina. It flowers from May to July, and ripens its berries early in the autumn. The flowers, which are the officinal portion, have a somewhat aromatic, though rather heavy odour. The berries as well as other parts of the plant are employed in domestic practice, and have been found to answer the same

purposes with the corresponding parts of the European elder, to which this species bears a very close affinity.

Sambucus nigra. Willd. *Sp. Plant.* i. 1495; Woodv. *Med. Bot.* p. 596. t. 211. The common elder of Europe differs from the American most obviously in its size, which approaches to that of a small tree. The stem is much branched towards the top, and has a rough whitish bark. The leaves are pinnate, consisting usually of five oval, pointed, serrate leaflets, four of which are in opposite pairs, and the fifth terminal. The flowers are small, whitish, and in five-parted cymes. The berries are globular, and of a blackish-purple colour when ripe.

The flowers have a peculiar sweetish odour, which is strong in their recent state, but becomes feeble by drying. Their taste is bitterish. They yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyraceous consistence. Water distilled from them contains an appreciable portion of ammonia. The berries are nearly inodorous, but have a sweetish acidulous taste, dependent on the saccharine matter and malic acid which they contain. Their expressed juice is susceptible of fermentation, and forms a vinous liquor used in the North of Europe. It is coloured violet by alkalies, and bright red by acids; and the colouring matter is precipitated blue by acetate of lead. The inner bark is without smell, its taste is at first sweetish, afterwards slightly bitter, acrid, and nauseous. Both water and alcohol extract its virtues, which are said to reside especially in the green layer between the liber and epidermis. According to Simon, the active principle of the inner bark of the root is a soft resin, which may be obtained by exhausting the powdered bark with alcohol, filtering the tincture, evaporating to the consistence of syrup, then adding ether, which dissolves the active matter, and finally evaporating to the consistence of a thick extract. Of this, twenty grains produces brisk vomiting and purging. (*Annal. der Pharm.* xxxi. 262.)

Medical Properties and Uses. The flowers are gently excitant and sudorific, but are seldom used except externally as a discutient in the form of poultice, fomentation, or ointment. The berries are diaphoretic and aperient; and their inspissated juice has enjoyed some reputation as a remedy in rheumatic, gouty, eruptive, and syphilitic affections. Its dose as an alterative diaphoretic is one or two drachms, as a laxative half an ounce or more. The inner bark is a hydragogue cathartic, acting also as an emetic in large doses. It has been employed in dropsy, and as an alterative in various chronic diseases. An ounce may be boiled with two pints of water to a pint, and four fluidounces of the decoction given for a dose. It is also sometimes used in vinous infusion. The leaves are not without activity, and the young leaf-buds are said to be a violent and even unsafe purgative. The juice of the root has been used as a diuretic in dropsy.

SANGUINARIA. U. S.

Bloodroot.

“The rhizoma of *Sanguinaria Canadensis*.” U. S.

SANGUINARIA. *Sex. Syst.* Polyandria Monogynia.—*Nat. Ord.* Papaveraceæ.

Gen. Ch. Calyx two-leaved. Petals eight. Stigma sessile, two-grooved.

Capsule superior, oblong, one-celled, two-valved, apex attenuated. *Receptacles* two, filiform, marginal. *Nuttall*.

Sanguinaria Canadensis. Willd. *Sp. Plant.* ii. 1140; Bigelow, *Am. Med. Bot.* i. 75; Barton, *Med. Bot.* i. 31. The *bloodroot*, or, as it is sometimes called, *puccoon*, is an herbaceous perennial plant. The root (rhizoma) is horizontal, abrupt, often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown colour on the outside, and brighter red within. It is furnished with numerous slender radicles, and makes offsets from the sides, which succeed the old plant. From the end of the root arise the scape and leafstalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channeled petiole, is reniform, somewhat heart-shaped, deeply lobed, smooth, yellowish-green on the upper surface, paler or glaucous on the under, and strongly marked by orange-coloured veins. The scape is erect, round, and smooth, rising from a few inches to a foot in height, and terminating in a single flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The germ is oblong and compressed, and supports a sessile, persistent stigma. The capsule is oblong, acute at both ends, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-coloured sap, which flows from every part when broken, but is of the deepest colour in the root.

The bloodroot is one of the earliest and most beautiful spring flowers of North America. It grows abundantly throughout the whole United States, delighting in loose rich soils, and shady situations, and flowering in March and April. After the fall of the flower, the leaves continue to increase in size, and by the middle of summer, have become so large as to give the plant an entirely different aspect. All parts of the plant are active, but the root only is officinal.

This, when dried, is in pieces from one to three inches long, from a quarter to half an inch or more in thickness, flattened, much wrinkled and twisted, often furnished with abrupt offsets and numerous short fibres, of a reddish-brown colour externally, with a spongy uneven fracture, the surface of which is at first bright orange, but becomes of a dull brown by long exposure. The colour of the powder is a brownish orange-red. *Sanguinaria* has a faint narcotic odour, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. It yields its virtues to water and alcohol. The late Dr. Dana, of New York, obtained from it a peculiar alkaline principle, denominated by him *sanguinarina*, upon which the acrimony, and perhaps the medical virtues of the root depend. It may be procured, according to Dana, by infusing the finely powdered root in hot water or diluted muriatic or acetic acid, precipitating with water of ammonia, collecting the precipitated matter, boiling it in water with pure animal charcoal, filtering off the water, exposing the residue left upon the filter to the action of alcohol, and finally evaporating the alcoholic solution. (*Ann. Lyc. of Nat. Hist. New York*, ii. 250.) *Sanguinarina*, thus obtained, is a white pearly substance, of an acrid taste, very sparingly soluble in water, soluble in ether, and very soluble in alcohol. With the acids it forms salts soluble in water, all of which have some shade of red, crimson, or scarlet, and form beautiful red solutions. They are acrid and pungent to the taste,

particularly the muriate and acetate. From these facts it would appear, that the red colour and acrid properties of the bloodroot may be owing to the presence of some native salt of sanguinarina, which is decomposed by ammonia in the process of separating the vegetable alkali.

The virtues of the root are said to be rapidly deteriorated by time.

Medical Properties and Uses. Sanguinaria is an acrid emetic, with stimulant and narcotic powers. In small doses it excites the stomach, and accelerates the circulation; more largely given, it produces nausea and consequent depression of the pulse; and in the full dose occasions active vomiting. The effects of an overdose are violent emesis, a burning sensation in the stomach, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. Four persons lost their lives at Bellevue Hospital, New York, in consequence of drinking largely of tincture of bloodroot, which they mistook for ardent spirit. (*Am. Journ. of Med. Sci.* N. S. ii. 506.) Snuffed up the nostrils, bloodroot excites much irritation, attended with sneezing. Upon fungous surfaces it acts as an escharotic. It has been given in typhoid pneumonia, catarrh, pertussis, croup, phthisis pulmonalis, rheumatism, jaundice, hydrothorax, and some other affections, either as an emetic, nauseant, or alterative; and its virtues are highly praised by many judicious practitioners.

The dose with a view to its emetic operation is from ten to twenty grains, given in powder or pill. The latter form is preferable in consequence of the great irritation of throat produced by the powder when swallowed. For other purposes, the dose is from one to five grains, repeated more or less frequently according to the effect desired. The medicine is sometimes given in infusion or decoction, in the proportion of half an ounce to the pint. The emetic dose of this preparation is from half a fluidounce to a fluidounce. The tincture is officinal. An infusion in vinegar has been employed advantageously, as a local application, in obstinate cutaneous affections.

Gen. Ch. Calyx five-toothed. Legume falcated, leafy, varicose, girted by a wing, not gaping. Seeds solitary. Willd.

Pterocarpus santalinus. Willd. *Sp. Plant.* iii. 906; Woodv. *Med. Bot.* p. 430. t. 156. This is a large tree with alternate branches, and petiolate ternate leaves, each simple leaf being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The flowers are yellow, in axillary spikes, and have a papilionaceous corolla, of which the vexillum is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the alæ spreading with their edges apparently toothed, and the carina oblong, short, and somewhat inflated. The tree is a native of India, attaining the highest perfection in mountainous districts, and in-

habiting especially the mountains of Coromandel and Ceylon. Its wood is the true officinal *red saunders*, though there is reason to believe that the product of other trees is sold by the same name.

The wood comes in roundish or angular billets, internally of a blood-red colour, externally brown from exposure to the air, compact, heavy, and of a fibrous texture. It is kept in the shops in the state of small chips, raspings, or coarse powder.

Red saunders has little smell or taste. It imparts a red colour to alcohol, ether, and alkaline solutions, but not to water; and a test is thus afforded by which it may be distinguished from some other colouring woods. The alcoholic tincture produces a deep violet precipitate with the sulphate of iron, a scarlet with the bichloride of mercury, and a violet with the soluble salts of lead. The colouring principle, which was separated by Pelletier, and called by him *santalin*, is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood prepared with an alkaline solution.

The wood has no medical virtues, and is employed solely for the purpose of imparting colour.

Soaps, in the most extended signification of the term, embrace all those compounds which result from the reaction of salifiable bases on oils and fats. Oils and fats, as has been explained under the titles *Olea* and *Adeps*, consist of three principles, two solid, differing in fusibility, called *stearin* and *margarin*, and one liquid, called *olein*, of which there are two varie-

ties. Stearin characterizes the fats which are firm and solid, as tallow; margarin, those that are soft like lard; and olëin the oils. When the oils and fats undergo *saponification* by reaction with a salifiable base, these three principles are decomposed into oily acids peculiar to each, discovered by Chevreul, and called stearic, margaric, and oleic acids, which unite with the base to form the soap, and into a sweet principle not saponifiable, called glycerin, which is set free. Hence it is inferred that stearin is a stearate, margarin a margarate, and olëin an oleate of glycerin, and that the oils and fats are mixtures of these three oily salts. Hence, also, it is obvious that soaps are mixed stearates, margarates, and oleates of various bases. *Stearic acid* is a firm white solid, fusible at 167° , greasy to the touch, pulverizable, soluble in alcohol, very soluble in ether, but insoluble in water. In the impure state it is used, as a substitute for wax, for making candles. *Margaric acid* has the appearance of fat, and is fusible at 140° . *Oleic acid* is an oily liquid, insoluble in water, soluble in alcohol and ether, lighter than water, crystallizable in needles a little below 32° , and having a slight smell and pungent taste. *Glycerin* (*oxide of glycerule, sweet principle of oils*) is a colourless, volatile, inflammable, syrupy liquid, without odour, having a very sweet taste, uniting in all proportions with water and alcohol, but insoluble in ether, and having a sp. gr. varying from 1.25 to 1.27.

Soaps are divided into the soluble and insoluble. The soluble soaps are combinations of the oily acids with soda, potassa, and ammonia; the insoluble consist of the same acids united with earths and metallic oxides. It is the soluble soaps only that are detergent, and it is to these that the name *soap* is generally applied. On the other hand the insoluble soaps, though not fit for use in domestic economy, are some of them employed in pharmacy; as, for example, the soap of the protoxide of lead, or lead plaster, and the soap of lime. (See *Emplastrum Plumbi* and *Linimentum Calcis*.)

The consistency of the fixed alkaline soaps depends partly on the nature of the oil or fat, and partly on the alkali present. Soaps are harder the more stearate and margarate they contain, and softer when the oleate predominates; and, as it respects the alkali present, they are harder when formed with soda, and softer when containing potassa. Hence it is that of pure soaps, considered as salts, stearate of soda is the hardest and most insoluble, and oleate of potassa the softest and most soluble.

The officinal soaps embrace three varieties; namely, two soda soaps, one made with olive oil (Castile soap), the other with animal oil (common soap); and one potassa soap (soft soap). The soap of ammonia is described under another head. (See *Linimentum Ammoniacæ*.)

Preparation. The following is an outline of the process for making soap. The oil or fat is boiled with a solution of caustic alkali, until the whole forms a thick mass which can be drawn out into long clear threads. After the soap is completely formed, the next step is to separate it from the excess of alkali, the glycerin, and redundant water. This is effected by adding common salt, or a very strong alkaline lye, in either of which the soap is insoluble. The same end may be attained by boiling down the solution, until the excess of alkali forms a strong alkaline solution, which acts the same part in separating the soap as the addition of a similar solution. As soon as the soap is completely separated it rises to the surface, and when it has ceased to froth in boiling, it is ladled out into wooden frames to congeal, after which it is cut into bars by means of a wire. The soap, as first separated, is called *grain soap*. It may be purified by dissolving it in an alkaline lye, and separating it by common salt. During this process the impurities subside, and the soap combines with more water; and hence

it becomes weaker, although purer and whiter. If the grain soap be not purified, it forms marbled soap, the streaks arising principally from an insoluble soap of oxide of iron. Sometimes the marbled appearance is produced by adding to the soap, as soon as it is completely separated, a fresh portion of lye, and immediately afterwards a solution of sulphate of iron. The black oxide of iron is precipitated, and gives rise to dark-coloured streaks, which, by exposure to the air, become red, in consequence of the conversion of the black into the sesquioxide of iron.

The officinal "*soap*" of the U. S. and London Pharmacopœias is an olive oil soda soap, made on the same general plan as that just explained. It is the *Sapo Durus* of the Edinburgh and Dublin Colleges.

Common soap (*Sapo Vulgaris*, U. S.) is also a soda soap; but instead of olive, it contains concrete animal oil. This soap corresponds with the white soap of Northern European countries and of the United States, and is formed usually from barilla and tallow. In Scotland it is manufactured from kelp and tallow. It was introduced into the list of the U. S. Pharmacopœia as the only proper soap for making opodeldoc. (See *Linimentum Saponis Camphoratum*.)

Soft soap (*Sapo Mollis*) is prepared on the same general principles as hard soap; potash being employed as the alkali, and a fatty matter, rich in oléin, as the oil. The French soft soap is made with the seed oils, such as rape seed, hemp seed, &c.; the Scotch and Irish, with fish oil and some tallow; and our own with refuse fat and grease. A lye of wood-ashes is the form of potash usually employed. In forming this soap it is necessary that it should continue dissolved in the alkaline solution, instead of being separated from it. Hence soft soap is a soap of potassa, completely dissolved in the solution of its alkali, which consequently is present in excess. A soap of potassa is sometimes made with a view to its conversion into a soda soap. This conversion is effected by the addition of common salt, which, by double decomposition, generates a soap of soda, and chloride of potassium in solution. After this change is effected, the addition of a further portion of salt separates the soda soap formed. It is evident that here the common salt performs a double office, and must be added in larger amount than when it is merely used as a separating agent.

Besides the officinal soaps of the United States and British Pharmacopœias, there are many other varieties, more or less used for medicinal or economical purposes. The officinal soap of the French Codex, called *amygdaline soap* (*almond oil soap*), is formed of caustic soda and almond oil, and is directed to be kept for two months, exposed to the air, before being used. *Starkey's soap*, also officinal in the Codex, is prepared by uniting, by trituration, equal parts of carbonate of potassa, oil of turpentine, and Venice turpentine. *Beef's marrow soap* is a fine animal oil soap, also included in the French standard of pharmacy. *Windsor soap* is a scented soda soap, made of one part of olive oil and nine parts of tallow. *Eau de luce* (*aqua lucis*) is a kind of liquid soap, formed by mixing a tincture of oil of amber and balsam of Gilead with water of ammonia. *Transparent soap* is prepared by saponifying kidney fat with soda free from foreign salts, drying the resulting soap, dissolving it in alcohol, filtering and evaporating the solution, and running it into moulds when sufficiently concentrated. This soap is yellow or yellowish-brown, and preserves its transparency after desiccation. *Palm soap* is prepared from palm oil and soda, to which tallow is added to increase its firmness. If it be wanted white, the palm oil must be bleached by exposure to the sun, by sulphuric acid, or by chlorine. This soap has a yellowish colour, and an agreeable odour of violets,

derived from the oil. *Soap balls* are prepared by dissolving soap in a small quantity of water, and then forming them with starch into a mass of the proper consistence. *Common yellow soap (rosin soap)* derives its peculiarities from an admixture of rosin and a little palm oil with the tallow employed; the oil being added to improve its colour.

All the varieties of soap, except a few of the fancy sort, and the olive oil soaps, are manufactured in the United States. The latter, which are chiefly used for medicinal purposes, are imported in largest quantity from France.

Properties. Soap, whatever may be its variety, has the same general properties. Its aspect and consistence are familiar to every one. Its smell is peculiar, and taste slightly alkaline. It is somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It is soluble in water, and more readily in hot than in cold. Potassa soaps and those containing oleic acid are far more soluble than the soda soaps, especially those in which the stearates and margarates predominate. Acids, added to an aqueous solution of soap, combine with the alkali, and set free the oily acids, which, being diffused through the water, give it a milky appearance. Its decomposition is also produced by metallic salts, which invariably give rise to insoluble soaps. Soap is soluble in cold, and abundantly in boiling alcohol. This solution constitutes the *tincture of soap*, and forms a very convenient test for discovering earthy salts in mineral waters. The use of soap as a detergent depends upon its power of rendering grease and other soiling substances soluble in water, and, therefore, capable of being removed by washing. Sometimes soap is adulterated with lime, gypsum, or pipe-clay, in which case it will not be entirely soluble in alcohol.

Olive oil soda soap (Sapo, U. S., Lond.), otherwise called *Castile* or *Spanish soap*, is a hard soap, and is presented under two principal varieties, the white and the marbled. *White Castile soap*, when good, is of a pale grayish-white colour, incapable of giving an oily stain to paper, devoid of rancid odour or strong alkaline qualities, and entirely soluble both in water and alcohol. It should not feel greasy, nor grow moist, but, on the contrary, should become dry by exposure to the air, without exhibiting any saline efflorescence. This variety of soap contains about twenty-one per cent. of water. Sometimes it contains a larger proportion of water, with which the soap is made to combine by the manufacturer, with the fraudulent intention of increasing its weight. Soap, thus adulterated, is known by its unusual whiteness, and by its suffering a great loss of weight in a dry air. *Marbled Castile soap* is harder, more alkaline, and more constant in its proportions than the other variety. It contains about fourteen per cent. of water. Containing less water than the white Castile, it is a stronger and more economical soap; but at the same time less pure. The impurity arises from the veins of marbling, which consist of ferruginous matter, as already explained.

Animal oil soda soap (Sapo Vulgaris, U. S.) is a hard soap, of a white colour, inclining to yellow. It is made from tallow and caustic soda. This soap possesses the same general properties as the olive oil soda soap.

Soft soap, as made in this country, is a semi-fluid slippery mass, capable of being poured from one vessel to another, and of a dirty yellow colour. This soap always contains an excess of alkali, which causes it to act more powerfully as a detergent than hard soap. The London and Edinburgh Colleges direct it to be made from olive oil and potash; but Dr. Pereira states that he has not been able to meet with it in England. That which is

made in France has a greenish colour and the consistence of soft ointment, and is obtained from potash and hemp-seed oil. It is called in the French Codex, *savon vert*. Sometimes it is manufactured from the dregs of olive oil.

Incompatibles. Soap is decomposed by all the acids, earths, and earthy and metallic salts. Acids combine with the alkali, and set free the oily acids of the soap; the earths unite with the oily acids and separate the alkali; while the salts mentioned give rise, by double decomposition, to an insoluble soap of their base, and a saline combination between their acid and the alkali of the soap. Hard waters, in consequence of their containing salts of lime, decompose and curdle soap. They may be rendered soft and fit for washing, by adding sufficient carbonate of soda, or carbonate of potassa, to precipitate all the lime.

Composition. It has been already explained that soap consists of certain oily acids, united with an alkali. As olive oil is a compound of margaric acid and olein, so the officinal "soap" is a mixed margarate and oleate of soda. The officinal "common soap" is principally a stearate of soda, and "soft soap," as defined by the London and Edinburgh Colleges, is a mixed margarate and oleate of potassa. The most important soaps have the following composition in the hundred parts. *Marseilles white soap*, soda 10·24, margaric acid 9·20, oleic acid 59·20, water 21·36. (*Braconnot.*) *Castile soap*, very dry, soda 9·0, oily acids 76·5, water 14·5. (*Ure.*) *Glasgow soft soap*, potassa 9·0, oily acids 43·7, water 47·3. (*Ure.*) *French soft soap*, potassa 9·5, oily acids 44, water 46·5. (*Thenard.*) Most soaps, it is perceived, contain a large proportion of water.

Medical Properties. Soap possesses the properties of a laxative, antacid, and antilithic. It is seldom given alone, but frequently in combination with rhubarb, the astringency of which it has a tendency to correct. Thus combined, it is frequently administered in dyspepsia, attended with constipation and torpor of the liver. As it is readily decomposed by the weakest acids, which combine with the alkali, it has proved useful in acidity of the stomach, and has been recommended as a remedy in the uric acid diathesis; but it possesses no power to dissolve calculi, as was once supposed. Externally, soap is a stimulating discutient, and as such has been used, by friction, in sprains and bruises. Dr. A. T. Thomson has seen much benefit derived from rubbing the tumid abdomen of children in mesenteric fever, morning and evening, with a strong lather of soap. In constipation of the bowels, especially when arising from hardened feces in the rectum, a strong solution of soap, especially of soft soap, forms a useful enema. When the latter is employed, two tablespoonfuls may be dissolved in a pint of warm water. In pharmacy, soap is frequently employed for the purpose of giving a proper consistence to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It is also an ingredient in some liniments and plasters. In toxicology it is used as a counterpoison for the mineral acids, and should always be resorted to in poisoning by these agents without a moment's delay, and its use continued, until magnesia, chalk, lime, or the bicarbonate of soda or of potassa can be obtained. The mode of administration, in these cases, is to give a teacupful of a solution of soap, made by dissolving it in four times its weight of water, every three or four minutes, until the patient has taken as much as he can swallow. The dose of soap is from five grains to half a drachm, given in the form of pill.

SARSAPARILLA. *U. S., Dub.*

Sarsaparilla.

“The root of *Smilax officinalis* and of other species of *Smilax*.” *U. S.*
 “*Smilax Sarsaparilla. Radix.*” *Dub.*

Off. Syn. SARZA. *Smilax officinalis. Radix. Lond.*; SARZA. Root of *Smilax officinalis*, and probably other species. *Ed.*

Salsepareille, *Fr.*; Sarsaparille, *Germ.*; Salsapariglia, *Ital.*; Zarzaparrilla, *Span.*

SMILAX. *Sex. Syst.* Diœcia Hexandria.—*Nat. Ord.* Smilacææ.

Gen. Ch. MALE. *Calyx* six-leaved. *Corolla* none. FEMALE. *Calyx* six-leaved. *Corolla* none. *Styles* three. *Berry* three-celled. *Seeds* two. *Willd.*

Until recently, the *Smilax Sarsaparilla* was admitted by most of the standard authorities as the source of this drug; but it is doubtful whether any of the sarsaparilla of the shops was ever obtained from that species. The *S. Sarsaparilla* is a native of the United States, and its root would certainly have been dug up and brought into the market, had it been found to possess the same properties with the imported medicine. It is not among the eleven species of *Smilax* described by Humboldt, Bonpland, and Kunth, who indicate the *S. officinalis*, *S. syphilitica*, and *S. Cumanensis*, especially the first, as the probable sources of the sarsaparilla exported from Mexico and the Spanish Main. In the present state of our knowledge on the subject, it is impossible to decide with certainty from what species the several commercial varieties of the drug are respectively derived. This much is nearly certain, that they do not proceed from the same plant. Of the great number of species belonging to this genus, very few possess any useful medicinal power; and Hancock states that of the six or eight which he found growing in the woods of Guiana, only one presented in any degree the sensible properties of the genuine sarsaparilla, the rest being insipid and inert. The root (rhizoma) of the *Smilax China*, a native of China and Japan, has been employed under the name of *China root* for similar purposes with the officinal sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown colour externally, whitish or of a light flesh-colour internally, without odour, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid like that of sarsaparilla. The root of the *Smilax aspera* is said to be employed in the South of Europe as a substitute for sarsaparilla; but it has little reputation. The East India sarsaparilla, which was at one time supposed to be the product of this species of *Smilax*, is derived from a wholly different plant, named *Hemidesmus Indicus*. We shall briefly describe the *S. Sarsaparilla*, on account of its former officinal rank, and afterwards such other species as are believed to yield any portion of the drug. All of these species are climbing or trailing plants, with prickly stems; a character expressed in the name of the medi-

cine, which is derived from two Spanish words (*zarza* and *parilla*) signifying a small thorny vine.

Smilax Sarsaparilla. Willd. *Sp. Plant.* iv. 776; Woodv. *Med. Bot.* p. 161. t. 62. The stem of this plant is long, slender, shrubby, angular, and beset with prickles. The leaves are unarmed, ovate lanceolate, with about five nerves, somewhat glaucous beneath, and supported alternately upon footstalks, at the bases of which are long tendrils. The flowers usually stand three or four together, upon a common peduncle, which is longer than the leafstalk. This species is indigenous, growing in swamps and hedges in the Middle and Southern States.

S. officinalis. Humb. and Bonpl. *Plant. Æquinoct.* i. 271. In this species the stem is twining, angular, smooth, and prickly; the young shoots are unarmed; and the leaves ovate oblong, acute, cordiform, five or seven-nerved, coriaceous, smooth, twelve inches long and four or five broad, with footstalks an inch long, smooth, and furnished with tendrils. The young leaves are lanceolate oblong, acuminate, and three-nerved. According to Humboldt, the plant abounds on the river Magdalena, in New Granada, where it is called *zarzaparilla* by the natives. Large quantities of the root are sent down the river to Mompox and Carthagena.

S. siphilitica. Willd. *Sp. Plant.* iv. 780. The stem is round and smooth; armed at the joints with from two to four thick, straight prickles; and furnished with oblong lanceolate, acuminate, three-nerved, coriaceous, shining leaves, which are a foot in length, and terminate by a long point. The plant was seen by Humboldt and Bonpland in New Granada, upon the banks of the river Cassiquiare, and by Martius in Brazil, at Yupura and by the Rio Negro. It is supposed to yield the Brazilian sarsaparilla.

S. medica. Schlechtendahl, in *Linnæa*, vi. 47. This species has an angular stem, armed with straight prickles at the joints, and a few hooked ones in the intervals. The leaves are smooth, bright green on both sides, shortly acuminate, five-nerved, with the veins prominent beneath. They vary much in form, the lower being cordate, auriculate-hastate; the upper cordate-ovate. In the old leaves, the petiole and midrib are armed with straight subulate prickles. The inflorescence is an umbel of from eight to twelve flowers, with a smooth axillary peduncle, and pedicels about three lines long. Shiede found this plant on the eastern declivity of the Mexican Andes, where the root is collected to be taken to Vera Cruz.

The medicinal species of *Smilax* grow in Mexico, Guatemala, and the warm latitudes of South America. The roots are very long and slender, and originate in great numbers from a common head or rhizoma, from which the stems of the plant rise. The whole root with the rhizoma is usually dug up, and as brought into market exhibits not unfrequently portions of the stems attached, sometimes several inches in length. The sarsaparilla of commerce comes from different sources, and is divided into varieties according to the place of collection or shipment.

Honduras Sarsaparilla is the variety most used in this country. It is brought from the bay of *Honduras*, and comes in bundles two or three feet long, composed of several roots folded lengthwise, and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing one hundred pounds or more. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached. In some bundles are many small fibres either lying loose or still adhering to the roots. The colour of the roots externally is a dirty grayish or reddish-brown; and the cortical portion beneath the epidermis often appears amylaceous when broken.

The *Jamaica* or *red sarsaparilla* of foreign writers is little known by that name in the United States. The island of Jamaica is merely its channel of exportation to Europe, and it is probably derived originally from Honduras. It does not materially differ in properties from Honduras sarsaparilla, its chief peculiarity being the reddish colour of the epidermis, which is also sometimes found in that variety. It is said also to yield a larger proportion of extract, and to contain less starch. As found in commerce, it is in bundles twelve or eighteen inches long, by four or five in thickness, consisting of long slender roots folded up, with numerous radical fibres attached.

Considerable quantities of the drug are imported from the Mexican ports of Vera Cruz and Tampico. The *Vera Cruz sarsaparilla* comes in large, rather loose bales, weighing about two hundred pounds, bound with cords or leather thongs, and usually containing the roots folded upon themselves, and separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much soiled with earth. This variety is not highly esteemed; but from the acrid taste which it possesses, it is probably not inferior in real virtues to the other kinds. It is probably derived from the *Smilax medica*.

Another variety is the *Caracas sarsaparilla*, brought in large quantities from La Guayra. It is in oblong packages, of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, and leave much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and with greater care. The radicles are often very amylaceous internally, in this respect resembling the following.

The *Brazilian*, or, as it is sometimes called in Europe, the *Lisbon sarsaparilla*, is less used in the United States than in Europe, where it has commanded a higher price. It has recently, however, been imported in considerable quantities. It comes from the ports of Para and Maranhão, in cylindrical bundles of from three to five feet in length, by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizoma) and stems, and having few radical fibres. It is the variety of which Hancock speaks as celebrated throughout South America by the name of *sarsa of the Rio Negro*, and is considered as the most valuable variety of the drug. It is distinguished by the amylaceous character of its interior structure, and has considerable acrimony. It is said by Martius to be derived from the *Smilax syphilitica*; but Dr. Hancock considers that portion of it which comes from the Rio Negro, and is shipped at Para, as the product of an undescribed species, certainly not the *S. syphilitica*.

Much sarsaparilla has been imported into England from Lima, Valparaíso, and other places on the Pacific coast of South America. It is described by Pereira as bearing a close resemblance to Jamaica sarsaparilla, but yielding a smaller proportion of extract. It is in bundles of about three feet long and nine inches thick, consisting of the roots folded with their heads or rhizoma attached. The epidermis is brown or grayish-brown. Sometimes roots of a light clay colour are found in the bundles.

Properties. The dried sarsaparilla roots are several feet in length, about the thickness of a goose-quill, cylindrical, more or less wrinkled longitudinally, flexible, and composed of a thick exterior cortical portion covered with a thin easily separable epidermis, of an inner layer of ligneous fibre, and of a central pith. The epidermis is of various colours, generally

ash-coloured, grayish-brown, or reddish-brown, and sometimes very dark. The cortical portion is in some specimens whitish, in others brown, and not unfrequently of a pink or rosy hue. It is occasionally white, brittle, and almost powdery like starch. The woody part is usually very thin, and composed of longitudinal fibres, which allow the root to be split with facility through its whole length. The central medulla often abounds in starch.

Sarsaparilla in its ordinary state is nearly or quite inodorous, but in decoction acquires a decided and peculiar smell. To the taste it is mucilaginous and very slightly bitter, and, when chewed for some time, produces a disagreeable acrid impression which remains long in the mouth and fauces. The root is efficient in proportion as it possesses this acrimony, which is said by some authors to be confined to the cortical portion, while the ligneous fibre and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes; and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water cold or hot, but are impaired by long boiling. (See *Decoctum Sarsaparillæ*.) They are extracted also by diluted alcohol. According to Hancock, the whole of the active principle is not extracted by water. He observes in his paper upon sarsaparilla, published in the London Medico-Botanical Transactions, when speaking of the sarsaparilla from Para and the Rio Negro, "after exhausting half a pound of this sort by two digestions, boiling and pressure, I added to the dregs half a pint of proof spirit, and digested this with a gentle heat for a few hours in a close vessel, then affusing hot water to the amount of that taken off from the first boiling, and pressing again, I procured by the last operation about four pints of an infusion which possessed the acrid properties of the sarsa in a much higher degree even than that obtained by the first decoction with simple water." It appears that in South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous fermentation, and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists.*

According to M. Thubeuf, sarsaparilla contains, 1. a peculiar crystalline substance, which is probably the active principle of the root, 2. a colouring substance, 3. resin, 4. starch, 5. lignin, 6. a thick, aromatic fixed oil, 7. a waxy substance, and 8. chloride of potassium and nitrate of potassa. It is said also to contain a minute proportion of volatile oil, and Batka found gum, bassorin, albumen, gluten and gliadine, lactic and acetic acids, and various salts. The proportion of starch is large.

Sarsaparillin. (*Smilacin. Pariglin. Salseparine. Parallinic acid.*) The crystalline principle in which the virtues of sarsaparilla reside should be called *sarsaparillin*. It was first discovered by Dr. Palotta, who described it in 1824, under the name of *pariglin*. Subsequently, M. Folchi supposed that he had found another principle which he called *smilacin*. In 1831, M. Thubeuf announced the discovery of a new substance in sarsaparilla, which he named *salseparine*, from the French name of the root. Finally, Batka, a German chemist, towards the end of 1833, published an account of a principle which he had discovered in the root, and which, under the impression that it possessed acid properties, he called

* See a paper by M. Soubeiran, Journ. de Pharm. tom. xvi. p. 38. an. 1830.

parillinic acid. M. Poggiale, however, has shown that these substances are identical, though procured by different processes. The process of M. Thu-beuf, which is decidedly preferable to the others, is the following. The root is treated with hot alcohol till deprived of taste. The tincture thus obtained is submitted to distillation, and seven-eighths of the alcohol drawn off. The remainder is treated with animal charcoal, and filtered at the end of twenty-four or forty-eight hours. The sarsaparillin is deposited in the form of a granular powder. This is dissolved in a fresh portion of alcohol and crystallized. The alcoholic mother liquors may be deprived of that portion of the principle which they retain by evaporating to dryness, dissolving the product in water, filtering, again evaporating to dryness, redissolving in alcohol, and crystallizing. *Sarsaparillin* is white, inodorous, almost tasteless in the solid state, but of a bitter, acrid, nauseous taste, when dissolved in alcohol or water. It is very slightly soluble in cold water, but is more readily dissolved by boiling water which deposits it on cooling. It is very soluble in alcohol, especially at a boiling temperature. Ether and the volatile oils also dissolve it. Water which holds it in solution has the property of frothing very much by agitation. M. Beral states that he has procured it pure by distilling, by means of a salt-water bath, a tincture of sarsaparilla prepared with very dilute alcohol. In that case, it must be considered volatile, and we can readily understand why sarsaparilla suffers in decoction. (*Am. Journ. of Pharm.* xii. 245. from *Journ. de Chim. Med.*) The solutions of sarsaparillin are without either acid or alkaline reaction. Batka erred in considering it an acid. M. Poggiale found it both in the cortical and medullary part of the root, but most largely in the former. Palotta gave it internally in doses varying from two to thirteen grains, and found it to produce nausea and to diminish the force of the circulation. It is probably the principle upon which sarsaparilla depends chiefly, if not exclusively, for its remedial powers; but this opinion needs the support of further observation before it can be admitted as an established fact. (*Journ. de Pharm.* xx. 553 and 679.)

The sarsaparilla of the shops is very apt to be nearly if not quite inert, either from age, or from having been obtained from an inferior species of *Smilax*. This inequality of the medicine, together with the improper modes of preparing it which have been long in vogue, has probably contributed to its variable reputation. The only criterion of good sarsaparilla which can be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert.

Medical Properties and Uses. Few medicines have undergone greater changes of reputation. About the middle of the sixteenth century it was introduced into Europe as a remedy for the venereal complaint, in the treatment of which it had been found very useful in the recent Spanish settlements in the West Indies. After a time it fell into disrepute, and was little employed till about a century ago, when it was again brought into notice by Sir William Fordyce and others, as a useful adjuvant and corrigent of mercury in lues venerea. Since that period very different opinions have been entertained of its efficacy. Some, among whom was Dr. Cullen, considered it wholly inert; others, on the contrary, have had the most unbounded confidence in its powers. The probable cause of much of this discrepancy has been already mentioned. Experience, both among regular practitioners and empirics, would seem to have placed its efficiency beyond reasonable doubt; and at this moment its reputation is probably as high as at any former period. Its most extensive and useful application is to the

treatment of secondary syphilis and syphiloid diseases, and that shattered state of the system which sometimes follows the imprudent use of mercury in these affections. It is also employed, though with less obvious benefit, in chronic rheumatism, scrofulous affections, certain cutaneous diseases, and other depraved conditions of the general health to which the physician may find it difficult to apply a name. Its mode of action is less evident than its ultimate effects. It is said to increase the perspiration and urine; but allowing it to possess this power, the amount of effect is too trifling to explain its influence over disease; and the diaphoretic and diuretic action which it appears to evince, may perhaps be as justly ascribed to the medicines with which it is generally associated, or the liquid in which it is exhibited. In this ignorance of its precise *modus operandi* we may call it an alterative, as we call all those medicines which change existing morbid actions, without any obvious influence over any of the functions.

Sarsaparilla may be given in powder in the dose of half a drachm three or four times a day. Dr. Hewson, of Philadelphia, informed us that he had found, as the result of numerous trials, that few stomachs would bear comfortably more than this quantity of the powder. The medicine, however, is more conveniently administered in the form of infusion, decoction, syrup, or extract. (*See the several officinal preparations in Part II.*) A beer made by fermenting an infusion of the drug with molasses, is said to be a popular remedy in South America.*

SASSAFRAS MEDULLA. U.S.

Sassafras Pith.

“The pith of the stems of *Laurus Sassafras*.” *U. S.*

SASSAFRAS RADICIS CORTEX. U.S.

Bark of Sassafras Root.

“The bark of the root of *Laurus Sassafras*.” *U. S.*

Off. Syn. SASSAFRAS. *Laurus Sassafras. Radix. Lond.*; SASSAFRAS. Root of *Sassafras officinale. Ed.*; SASSAFRAS. LAURUS SASSAFRAS. *Lignum. Radix. Dub.*

Sassafras, Fr., Germ.; *Sassafras, Sassafrasso, Ital.*; *Sasafras, Span.*

In the new distribution of the species composing the genus *Laurus* of Linnæus, the sassafras tree has been made the type of a new genus, denominated *Sassafras*, which should have been admitted in our Pharmacopœia; as the new arrangement was recognised in the adoption of the genus *Cinnamomum*.

* The following is a formula recommended by Hancock. “Take of Rio Negro sarsa, bruised, 2 lb.; bark of guaiac, powdered, 8 oz.; raspings of guaiac wood, anise seeds, and liquorice root, each 4 oz.; mezereon, bark of the root, 2 oz.; treacle [molasses] 2 lb.; and a dozen bruised cloves; pour upon these ingredients about four gallons of boiling water, and shake the vessel thrice a day. When a fermentation has well begun, it is fit for use, and may be taken in the dose of a small tumblerful twice or thrice a day.” This formula is worthy of attention; but the bark of guaiacum, which is not kept in the shops, might be omitted, or replaced by the wood, without materially affecting the virtues of the preparation.

SASSAFRAS. *Sex. Syst.* Enneandria Monogynia.—*Nat. Ord.* Lauraceæ.

Gen. Ch. Diœcious. *Calyx* six-parted, membranous; segments equal, permanent at the base. **MALES.** *Fertile stamens* nine, in three rows, the three inner with double stalked distinct glands at the base. *Anthers* linear, four-celled, all looking inwards. **FEMALES,** with as many sterile stamens as the males or fewer; the inner often confluent. *Fruit* succulent, placed on the thick fleshy apex of the peduncle, and seated in the torn unchanged calyx. (*Lindley.*)

Sassafras officinale. Nees, *Laurin.* 488.—*Laurus Sassafras.* Willd. *Sp. Plant.* ii. 485; Bigelow, *Am. Med. Bot.* ii. 142; Michaux. *N. Am. Sylv.* ii. 144. This is an indigenous tree of middling size; rising in favourable situations from thirty to fifty feet in height, with a trunk about a foot in diameter. In the Southern States it is sometimes larger, and in the northern parts of New England is little more than a shrub. The bark which covers the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side; but the greater number are three-lobed. Their mean length is four or five inches. The flowers, which are frequently diœcious, and appear before the leaves, are small, of a pale yellowish-green colour, and disposed in racemes which spring from the branches below the leaves, and have linear bractes at their base. The corolla is divided into six oblong segments. The male flowers have nine stamens; the hermaphrodite, which are on a different plant, have only six, with a simple style. The fruit is an oval drupe, about as large as a pea, of a deep blue colour when ripe, and supported on a red pedicel, which enlarges at the extremity into a cup for its reception.

The sassafras is common throughout the United States, and extends into Mexico. It is said also to grow in Brazil and Cochin-china; but the plants observed in these places were probably not of the same species. In this country the sassafras is found both in woods and open places, and is apt to spring up in the neighbourhood of cultivation, and in neglected or abandoned fields. In Pennsylvania and New York it blooms in the beginning of May; but much earlier at the South. The fresh flowers have a slightly fragrant odour, and almost all parts of the plant are more or less aromatic. The wood and root are directed by the British Pharmacopœias, the bark of the root, and the pith of the twigs or extreme branches, by that of the United States. The wood is porous, light, fragile, whitish in the young tree, reddish in the old, and but feebly endowed with aromatic properties. It is sent to Europe in billets invested with the bark; but is not employed in this country. The root is more commonly exported, and is the part chiefly used in British pharmacy. It consists of a brownish-white wood, covered with a spongy bark divisible into layers. The latter portion is by far the most active, and is usually kept in our shops in a separate state.

1. *Sassafras Pith.* This is in slender cylindrical pieces, very light and spongy, with a mucilaginous taste, having in a slight degree the characteristic flavour of the sassafras. It abounds in a gummy matter which it readily imparts to water, forming a limpid mucilage, which, though ropy and viscid, has much less tenacity than that of gum Arabic, and will not answer as a substitute in the suspension of insoluble substances. It differs also from solutions of ordinary gum, in remaining perfectly limpid when added to alcohol. This mucilage is much employed as a mild and soothing application in inflammation of the eyes; and forms a pleasant and useful drink in

dysenteric, catarrhal, and nephritic diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

2. *Bark of Sassafras Root.* As found in the shops, this is usually in small irregular fragments, sometimes invested with a brownish epidermis, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter colour than that of the exposed surfaces. Its odour is highly fragrant, its taste sweetish, and gratefully aromatic. These properties are extracted by water and alcohol. They reside in a volatile oil which may be obtained separate by distillation with water. (See *Oleum Sassafras*.)

Medical Properties and Uses. The bark of sassafras root is stimulant, and perhaps diaphoretic, though its possession of any peculiar tendency to the skin, independently of its mere excitant property, is quite doubtful. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavour of which it improves, while it renders them more cordial to the stomach. The complaints for which it has been particularly recommended, are chronic rheumatism, cutaneous eruptions, and scorbutic and syphilitic affections. As a remedy in lues venerea, in which it formerly had a high reputation, it is now universally considered as in itself wholly inefficient. It is most conveniently administered in the form of infusion. The oil may also be given. As the active principle is volatile, the decoction and extract are useless preparations.

Gen. Ch. *Corolla* campanulate. *Style* one. *Stigmas* two, linear-cylindrical, often revolute. *Ovary* two-celled, four-seeded. *Capsule* two-celled. (*Lindley.*)

Convolvulus Scammonia. Willd. *Sp. Plant.* i. 845; Woodv. *Med. Bot.* p. 243. t. 86. This species of *Convolvulus* has a perennial, tapering root, from three to four feet long, from nine to twelve inches in circumference, branching towards its lower extremity, covered with a light gray bark, and containing a milky juice. The stems are numerous, slender, and twining, extending sometimes to the distance of fifteen or twenty feet upon the ground, or on neighbouring plants, and furnished with smooth, bright green, arrow-shaped leaves, which stand alternately upon long footstalks. The flowers are placed in pairs, or three together upon the peduncles, which are round, axillary, solitary, and of nearly twice the length of the leaf.

The plant is a native of Syria and the neighbouring countries. No part is medicinal except the root, which, when dried, was found by Dr. Russel to be a mild cathartic. Scammony is the concrete juice of the fresh root, and is collected, according to Russel, in the following manner. In the month

of June, the earth is cleared away from about the root, the top of which is cut off obliquely about two inches from the origin of the stems. The milky juice which exudes is collected in shells or other convenient receptacle, placed at the most depending part of the cut surface. A few drachms only are collected from each root. The juice from several plants is put into any convenient vessel, and concretes by time. In this state it constitutes genuine scammony, but is very seldom exported. It is generally prepared for the market by admixture, while it is yet soft, with the expressed juice of the stalks and leaves, with wheat flour, ashes, fine sand, &c.; and it has been supposed that scammony sometimes consists wholly or in great part of the expressed juice of the root, evaporated to dryness by exposure to the sun, or by artificial heat. The drug is exported chiefly from Smyrna, though small quantities are said to be sent out of the country at Alexandretta, the seaport of Aleppo. Dr. Pereira was informed by a merchant who had resided in Smyrna, that it is brought upon camels in a soft state into that city, and afterwards adulterated by a set of individuals called scammony makers. The adulteration appears to be conducted in conformity with a certain understood scale, more or less foreign matter being added according to the price. The materials employed are chiefly chalk and some kind of flour or meal. Very little comparatively is exported perfectly pure. We obtain scammony either directly from Smyrna, or indirectly, through some of the Mediterranean ports.

The name of *Aleppo scammony* was formerly given to the better kinds of the drug, and of *Smyrna scammony* to those of inferior quality; the distinction having probably originated in some difference in the character of the scammony obtained at these two places. But no such difference now exists; as scammony is brought from Smyrna of every degree of purity. It is customary in this country to designate the genuine drug of whatever quality as *Aleppo scammony*; while the name of *Smyrna scammony* is given to a spurious article manufactured in the South of France, and to other factitious substitutes. It is quite time that these terms should be altogether abandoned. We shall treat of the drug under the heads of genuine and factitious scammony.

Genuine scammony. This is sent into commerce in drums or boxes, and is either in irregular lumps, in large solid masses of the shape of the containing vessel, into which it appears to have been introduced while yet soft, or in circular, flattish or plano-convex cakes. It seldom or never reaches us in an unmixed state. Formerly small portions of pure scammony were occasionally to be met with in Europe, contained in the shells in which the juice was collected and dried. This variety, denominated *scammony in shells*, is now scarcely to be found. The pure drug, as at present known in the shops of London, is called *virgin scammony*. It is described as in irregular pieces, probably the fragments of larger and roundish masses, often covered with a whitish-gray powder, friable and easily broken into small fragments between the fingers, with a shining grayish-green fracture soon passing into greenish-black, and exhibiting under the microscope minute air cells, and numerous gray semitransparent splinters. It is easily pulverized, affording a pale ash-gray powder. When rubbed with water it readily forms a milky emulsion. It has a rather strong, peculiar odour, which has been compared to that of old cheese. The taste is feeble at first, and afterwards somewhat acrid, but without bitterness. It gives no evidence, when the requisite tests are applied, of the presence of starch or carbonate of lime, leaves but a slight residue when burned, and yields about 80 per cent. of its weight to sulphuric ether.

The form of scammony at present almost exclusively found in our markets is that in circular cakes. These are sometimes flattish on both sides, but generally somewhat convex on one side and flat on the other, as if dried in a saucer, or other shallow vessel. They are five or six inches in diameter, and from half an inch to an inch and a half, or even two inches thick in the centre. As found in the retail shops, they are usually in fragments. They are hard and heavy, with a faintly shining roughish fracture; and when broken exhibit in general a structure very finely porous, sometimes almost compact, and in a very few instances cavernous. Their colour externally is a dark ash or dark olive, or slate colour approaching to black; internally somewhat lighter, and grayish, with an occasional tinge of green or yellow, but deepening by exposure. The small fragments are sometimes slightly translucent at the edges. The mass, though hard, is pulverizable without great difficulty, and affords a light-gray powder. It imparts to water with which it is triturated a greenish milky appearance. The smell is rather disagreeable, and similar to that of the pure drug. The taste, very slight at first, becomes feebly bitterish and acrid. This kind of scammony is never quite pure, and much of it is considerably adulterated. One of the finest specimens effervesced strongly with muriatic acid, in cold filtered decoction struck a deep blue with iodine, and afforded upon incineration 15 per cent. of ashes, which were dissolved by muriatic acid, and precipitated by sulphuric acid as sulphate of lime. In some of the cakes carbonate of lime is the chief impurity; in others the adulterating substance is probably meal, as evidences of the presence of starch and lignin are afforded; and in others again both these substances are found. Christison discovered in the chalky specimens a proportion of carbonate of lime varying from 15 to 38 per cent.; in the amylaceous, from 13 to 42 per cent. of impurity. It was probably to the flat, dark-coloured, compact, difficultly pulverizable, and more impure cakes that the name of *Smyrna scammony* was formerly given. These have been considered by some, without sufficient grounds, to be the product of the *Periploca Secamone*, a plant growing in Egypt.*

* Dr. Pereira, in his work on *Materia Medica*, describes the varieties of scammony as they exist in the London market. As these have interest for the druggist, we introduce a notice of them.

1. *Virgin Scammony. Pure Scammony. Lachryma Scammony.* The description of this corresponds with that of pure scammony given in the text. In addition, the following particulars may be mentioned. The whitish powder often found upon the surface effervesces with muriatic acid, and consists of chalk, in which the lumps have probably been rolled. The sp. gr. of the masses is 1.210. In the same piece it sometimes happens that certain portions are shining and black, while others are dull-grayish. Virgin scammony readily takes fire, and burns with a yellowish flame. This variety is now much more abundant in the shops of London than formerly.

2. *Scammony of second quality.* This is called *seconds* in commerce. It is in two forms. 1. In *irregular pieces*. This, in external appearance, brittleness, odour, and taste, resembles virgin scammony; but is distinguished by its greater sp. gr., which is 1.463, by its dull, very slightly shining fracture, and its grayish colour. The freshly broken surface effervesces with muriatic acid, but the cold decoction does not give a blue colour with iodine. It, therefore, contains chalk, but not fecula. 2. In *large regular masses*. This has the form of the drum or box in which it was imported, and into which it was probably introduced while soft. It has a dull grayish fracture, and the sp. gr. 1.359. It exhibits, with the appropriate tests, evidence of the presence both of chalk and fecula. It is sometimes found of a soft or cheesy consistence.

3. *Scammony of third quality.* This is called *thirds* in commerce. It is in circular flat cakes, about five inches in diameter and one inch thick. The cakes are dense, heavy, and more difficult to break than the preceding varieties. The fracture is sometimes resinous and shining, sometimes dull, and exhibits air cavities, and numerous white specks, which consist of chalk. The colour is grayish, or grayish-black. The sp. gr.

Scammony is ranked among the gum-resins. It is partially dissolved by water, much more largely by alcohol and ether, and almost entirely, when pure, by boiling diluted alcohol. Its active ingredient is resin, which constitutes about 80 per cent. of pure dry scammony. The gum-resin has been analyzed by various chemists, but the results are somewhat uncertain; as the character of the specimens examined is insufficiently determined by the terms Aleppo and Smyrna scammony, employed to designate them. Thus, Bouillon-Lagrange and Vogel obtained, from 100 parts of Aleppo scammony, 60 of resin, 3 of gum, 2 of extractive, and 35 of insoluble matter; from the same quantity of Smyrna scammony, 29 parts of resin, 8 of gum, 5 of extractive, and 58 of vegetable remains and earthy substances. It is obvious that both the specimens upon which they operated were very impure. Marquart found in pure scammony (*scammony in shells*) 81.25 per cent. of resin, 3.00 of gum with salts, 0.75 of wax, 4.50 of extractive, 1.75 of starchy envelopes, bassorin, and gluten, 1.50 of albumen and lignin, 3.75 of ferruginous alumina, chalk, and carbonate of magnesia, and 3.50 of sand. Christison found different specimens of pure scammony to contain, in 100 parts from 77 to 83 parts of resin, from 6 to 8 of gum, from 3.2 to 5 of lignin and sand, and from 7.2 to 12.6 of water, with occasionally a little starch, probably derived accidentally from the root, and not in sufficient quantity to cause a cold decoction of the gum-resin to give a blue colour with iodine. For the character of the resin see *Extractum sive Resina Scammonii*. As already stated, scammony is seldom or never quite pure as found in our shops. Much of it contains not more than 50 per cent. of the resin, and some not more than 42 per cent.*

The Edinburgh College gives the following signs of pure scammony. "Fracture glistening, almost resinous, if the specimen be old and dry; muriatic acid does not cause effervescence on its surface; the decoction of its powder, filtered and cooled, is not rendered blue by tincture of iodine. Sulphuric ether separates at least eighty per cent. of resin dried at 280°." Effervescence with muriatic acid indicates the presence of chalk, a blue colour with iodine that of starch in the form of flour.

Factitious Scammony. Montpelier Scammony. Much spurious scammony is manufactured, in the South of France, from the expressed juice of the *Cynanchum Monspeliacum*, incorporated with various resins, and other purgative substances. It is occasionally imported into the United States and sold as Smyrna scammony. It is usually in flat semicircular cakes, four or five inches in diameter, and six or eight lines thick, blackish

varies from 1.276 to 1.543. Both chalk and flour are detected by tests. In five different cakes, the quantity of chalk employed in the adulteration was stated by the importer to be, in 100 parts of the cakes respectively, 13.07, 23.1, 25.0, 31.05, and 37.54, numbers which correspond very closely, in the two extremes, with the results obtained by Christison. This is the variety of scammony referred to in the text as the one chiefly used in the United States.

* The following table is given by Dr. Christison as the result of his examination of different specimens of impure commercial scammony.

	Calcareous.			Amylaceous.		Calcareo-amylaceous.
Resin,	64.6	56.6	43.3	37.0	62.0	42.4
Gum,	6.8	5.0	8.2	9.0	7.2	7.8
Chalk,	17.6	25.0	31.6	—	—	18.6
Fecula,	—	1.4	4.0	20.0	10.4	13.2
Lignin and sand,	5.2	7.1	7.8	22.2	13.4	9.4
Water,	6.4	5.2	6.4	12.0	7.5	10.4
	100.6	100.3	101.3	100.2	100.5	101.8

both externally and within, very hard, compact, rather heavy, of a somewhat shining and resinous fracture, a feeble balsamic odour wholly different from that of genuine scammony, and a very bitter nauseous taste. When rubbed with the moistened finger it becomes dark-gray, unctuous, and tenacious. We have seen another substance sold as Smyrna scammony, which was obviously spurious, consisting of blackish, circular, flat cakes, or fragments of such cakes, rather more than half an inch thick, very light, penetrated with small holes as if worm-eaten, and when broken exhibiting an irregular, cellular, spongy texture. There is very little, if any, of this now in the market. Dr. Pereira describes another factitious scammony sold as *Smyrna scammony*, which is in circular flat cakes, about half an inch thick, blackish, and of a slaty aspect, breaking with difficulty, of a dull black fracture, and of the sp. gr. 1.412. Moistened and rubbed it has the smell of guaiacum, which may also be detected by chemical tests.

Medical Properties and Uses. Scammony is an energetic cathartic, apt to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who not only gave it as a purgative, but also applied it externally for the cure of various cutaneous diseases. It may be used in all cases of torpid bowels, when a powerful impression is desired; but on account of its occasional violence is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated. It should be given in emulsion with mucilage, sugar, almonds, liquorice or other demulcent; and its disposition to gripe may be counteracted by the addition of an aromatic. The dose is from five to fifteen grains of pure scammony, from ten to twenty of that commonly found in the market.

Squill.

“The bulb of *Scilla maritima*.” *U. S., Ed.* “*Scilla maritima. Bulbus recens.*” *Lond.*

Off. Syn. SCILLA MARITIMA. *Bulbus. Dub.*

Scille, Fr.; Meerzwiebel, Germ.; Scilla, Ital.; Cebolla albarrana, Span.

SCILLA. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Liliaceæ.

Gen. Ch. Corolla six-petaled, spreading, deciduous. Filaments thread-like. *Willd.*

Scilla maritima. Willd. *Sp. Plant.* ii. 125; Woodv. *Med. Bot.* p. 745. t. 255.—*Squilla maritima.* Steinheil; Lindley, *Flor. Med.* p. 591. This is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish peduncles, at the base of each of which is a linear, twisted, deciduous floral leaf.

The squill grows on the seacoast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the officinal portion. It is generally dried for use; but it is sometimes imported into this country in the recent state, packed in sand.

Properties. The fresh bulb is pear-shaped, usually larger than a man's fist, sometimes as large as the head of a child, and consisting of fleshy scales, attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two varieties, distinguished as the *red* and *white squill*. In the former, the exterior coating is of a deep reddish-brown colour, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter, the whole bulb is white. They do not differ in their medicinal virtues. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the abundance and viscid character of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of the active principle, the latter too fleshy and mucilaginous. The London College gives directions for the slicing and drying of the recent bulb.

Dried squill, as found in our shops, is in irregular oblong pieces, often more or less contorted, of a dull yellowish-white colour with a reddish or rosy tint, sometimes entirely white, slightly diaphanous, brittle and pulverizable when perfectly dry, but often flexible from the presence of moisture, for which they have a great affinity. Occasionally a parcel will be found consisting of vertical slices, some of which adhere together at their base. The odour is very feeble, the taste bitter, nauseous, and acrid.

The virtues of squill are extracted by water, alcohol, and vinegar. According to Vogel, it contains a peculiar very bitter principle named by him *scillitin*, gum, tannin, traces of citrate of lime and saccharine matter, lignin, and an acrid principle which he was unable to isolate. Water distilled from it had neither taste nor smell, and was drunk by Vogel to the amount of six ounces without producing any effect. From the experiments of Duncan and Buchner it appears, that tannin, if it exists in squill, is in very small proportion. The *scillitin* of Vogel is soluble in water, alcohol, and vinegar; but it is considered by M. Tilloy of Dijon, whose analysis is more recent, as a compound of the proper active principle of squill with gum and uncrySTALLIZABLE sugar. The *scillitin* obtained by the latter experimenter, was insoluble in water and in dilute acids, soluble in alcohol, exceedingly acrid and bitter to the taste, and very powerful in its influence on the animal system. A single grain produced the death of a strong dog. The following is the process of M. Tilloy. Dried squill is macerated in alcohol of 33° Baumé, the resulting tincture evaporated to the consistence of syrup, and the extract treated with alcohol of 35°. The alcoholic solution is evaporated, and the residue treated first with ether and subsequently with water. The aqueous solution, filtered and evaporated, yields a substance analogous to the *scillitin* of Vogel. To obtain the principle pure, the aqueous solution is treated with animal charcoal before evaporation. The matter obtained is dissolved in alcohol, ether is added to precipitate the sugar, and the active principle remains in the mixed liquor, from which it may be obtained by evaporation. According to M. Tilloy, this proceeding should be repeated several times. (*Dict. des Drogues.*) M. Chevallier thinks that the active principle of squill has not yet been entirely isolated. Landerer obtained a crystalline principle from fresh squill, by treating the bruised bulb with dilute sulphuric acid, concentrating the solution, neutralizing it with lime, drying the pre-

cipitate, exhausting this with alcohol, and evaporating the tincture, which, on cooling, deposited the substance in question in prismatic crystals. It is bitter, but not acrid, insoluble in water or the volatile oils, slightly soluble in alcohol, and, according to Landerer, capable of neutralizing the acids. (*Christison's Dispensatory*.)

When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture, it soon becomes mouldy.

Medical Properties and Uses. Squill is expectorant, diuretic, and in large doses emetic and purgative. In overdoses it has been known to occasion hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels. The Greek physicians employed it as a medicine; and it has retained to the present period a deserved popularity. As an expectorant, it is used both in cases of deficient and of superabundant secretion from the bronchial mucous membrane, in the former case usually combined with tartar emetic or ipecacuanha, in the latter frequently with the stimulant expectorants. In both instances, it operates by stimulating the vessels of the lungs; and where the inflammatory action in this organ is considerable, as in pneumonia and severe catarrh, the use of squill should be preceded by the lancet. In dropsical diseases it is very much employed, especially in connexion with calomel, which is supposed to excite the absorbents, while the squill increases the secretory action of the kidneys. It is thought to succeed best, in these complaints, in the absence of general inflammatory excitement. On account of its great uncertainty and occasional harshness, it is very seldom prescribed as an emetic, except in infantile croup or catarrh, in which it is usually given in the form of syrup or oxymel. When given in substance, it is most conveniently administered in the form of pill. The dose, as a diuretic or expectorant, is one grain, repeated two or three times a day, and gradually increased till it produces slight nausea, or evinces its action upon the kidneys or lungs. From six to twelve grains will generally vomit.

Cytisus Scoparius. *De Cand. Prodrum.* ii. 154.—*Spartium Scoparium.* *Willd. Sp. Plant.* iii. 933; *Woodv. Med. Bot.* p. 413. t. 150. This is a common European shrub, cultivated in our gardens, from three to eight feet high, with numerous straight, pentangular, bright-green, very flexible branches, and small, oblong, downy leaves, which are usually ternate,

but on the upper part of the plant are sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow colour, and supported solitarily upon short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures.

The whole plant has a bitter nauseous taste, and when bruised, a strong peculiar odour. The tops of the branches are the officinal portion; but the seeds are also used, and while they possess similar virtues have the advantage of keeping better. Water and alcohol extract their active properties.

Medical Properties and Uses. Broom is diuretic and cathartic, and in large doses emetic, and has been employed with great asserted advantage in dropsical complaints, in which it was recommended by Mead, Cullen, and others. Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce every hour till it operated by stool or urine. It is a domestic remedy in Great Britain, but is seldom used in this country. The seeds may be given in powder in the dose of ten or fifteen grains.

SCROPHULARIA NODOSA. Folia. *Dub.*

Figwort Leaves.

Scrophulaire noueuse, *Fr.*; Braunwurz, *Germ.*; Scrofolaria nodosa, *Ital.*; Eserofularia, *Span.*

SCROPHULARIA. *Sex. Syst.* Didynamia Angiospermia.—*Nat. Ord.* Scrophulariaceæ.

Gen. Ch. Calyx five-cleft. Corolla subglobular, resupine. Capsule two-celled. *Willd.*

Scrophularia nodosa. Willd. *Sp. Plant.* iii. 270; Smith, *Flor. Brit.* 663. The root of the knotty rooted figwort is perennial, tuberous, and knotty; the stem is herbaceous, erect, quadrangular, smooth, branching, and from two to three feet high; the leaves are opposite, petiolate, ovate cordate, pointed, sharply toothed, veined, and of a deep-green colour; the flowers are small, dark purple, slightly drooping, and borne on branching peduncles in erect terminal bunches.

The plant is a native of Europe, where it grows in shady and moist places, and flowers in July.

The leaves, which are the part used, have when fresh a rank fetid odour, and a bitter somewhat acrid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by the persulphate of iron.

Medical Properties and Uses. Figwort leaves are said to be anodyne and diuretic, and to have repellent properties when externally applied. They were formerly considered tonic, diaphoretic, discutient, anthelmintic, &c.; and were thought to be useful in scrofula. They are at present very little employed, and never in this country. In Europe they are sometimes applied in the form of ointment or fomentation to piles, painful tumours and ulcers, and cutaneous eruptions.

SENEGA. U.S., Lond., Ed.

Seneka.

"The root of Polygala Senega." U. S., Ed. "Polygala Senega. Radix." Lond.

Off. Syn. POLYGALA SENECA. Radix. Dub.

Polygale de Virginie, Fr.; Klapperschlangenwurzel, Germ.; Poligala Virginiana, Ital.

POLYGALA. Sex. Syst. Diadelphia Octandria.—Nat. Ord. Polygalaceæ.

Gen. Ch. Calyx five-leaved, with two leaflets wing-shaped, and coloured.

Legume obcordate, two-celled. Willd.

Besides the *P. Senega*, two other species have attracted some attention in Europe—the *P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but as they are not natives of this country, and are never used by practitioners here, they do not merit particular notice.

Polygala Senega. Willd. *Sp. Plant.* iii. 894; Bigelow, *Am. Med. Bot.* ii. 97; Barton, *Med. Bot.* ii. 111. This unostentatious plant has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple in their lower portion, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright green on the upper surface, paler beneath, and sessile or supported on very short footstalks. The flowers are small, white, and arranged in a close spike at the summit of the stem. The calyx is the most conspicuous part of the flower. It consists of five leaflets, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed. The capsules are small, much compressed, obcordate, two-valved, two-celled, and contain two oblong ovate, blackish seeds, pointed at one extremity.

This species of Polygala, commonly called *Seneka snakeroot*, grows wild in all parts of the United States, but most abundantly in the southern and western sections, where the root is collected in great quantities for sale. It is brought into market in bales weighing from fifty to four hundred pounds.

Properties. As the root occurs in commerce, it is of various sizes, from that of a straw to that of the little finger, presenting a thick knotty head, which exhibits traces of the numerous stems. It is tapering, branched, variously twisted, often marked with crowded annular protuberances, and with a projecting keel-like line, extending along its whole length. The epidermis is corrugated, transversely cracked, of a yellowish-brown colour in the young roots, and brownish-gray in the old. In the smaller branches the colour is a lighter yellow. The bark is hard and resinous, and contains the active principles of the root. The central portion is ligneous, white, and quite inert, and should be rejected in the preparation of the powder. The colour of this is gray. The odour of seneka is peculiar, strong in the fresh root, but faint in the dried. The taste is at first sweetish and mucilaginous, but after chewing becomes somewhat pungent and acrid, leaving a peculiar irritating sensation in the fauces. These properties, as well as the medical virtues of the root, are extracted by boiling water, and by alcohol. Diluted alcohol is an excellent solvent. The root has been analyzed by Gehlen, Peschier of Geneva, Feneulle of Cambray, Dulong D'Astafort, Folchi, and Trommsdorff, and more recently by M. Quevenne. Gehlen was supposed to have found the active principle in the substance left behind,

when the alcoholic extract is treated successively with ether and water, and the name of *senegin* was accordingly conferred upon it. But it does not seem to have any just claim to the rank assigned to it, though it probably contains the active principle among its constituents. Equally unfounded are the conclusions of those chemists, who believe that they have discovered an organic alkali in the root. From a comparison of the results obtained by the above mentioned chemists, it would appear that seneka contains, 1. a peculiar acrid principle, which M. Quevenne considers to be an acid, and has named *polygalic acid*; 2. a yellow colouring matter, of a bitter taste, insoluble or nearly so in water, but soluble in ether and alcohol; 3. a volatile principle, considered by some as an essential oil, but thought by Quevenne to possess acid properties, and named by him *virgineic acid*; 4. pectic acid or pectin; 5. tannic acid of the variety which precipitates iron green; 6. gum; 7. albumen; 8. cerin; 9. fixed oil; 10. woody fibre; and 11. saline and earthy substances, as the carbonates, sulphates, and phosphates of lime and potassa, chloride of potassium, alumina, magnesia, silica, and iron. The virtues of seneka appear to reside chiefly, if not exclusively, in the acrid principle which M. Quevenne called polygalic acid, and which he considered closely analogous to saponin. He obtained it pure by the following process. Powdered seneka is exhausted by alcohol of 33°, and so much of the alcohol is distilled off as to bring the resulting tincture to the consistence of syrup. The residue is treated with ether, in order to remove the fatty matter. The liquid upon standing deposits a precipitate, which is separated by filtration, and is then mixed with water. To the turbid solution thus formed alcohol is added, which facilitates the production of a white precipitate, consisting chiefly of polygalic acid. The liquid is allowed to stand for several days, that the precipitate may be fully formed. The supernatant liquid being decanted, the precipitate is drained upon a filter, and, being removed while yet moist, is dissolved by the aid of heat in alcohol of 36°. The solution is boiled with purified animal charcoal, and is filtered while hot. Upon cooling it deposits the principle in question in a state of purity. Thus obtained, polygalic acid is a white powder, inodorous, and of a taste at first slight, but soon becoming pungent and acrid, and producing a very painful sensation in the throat. It is fixed, unalterable in the air, inflammable, soluble in water slowly when cold and rapidly with the aid of heat, soluble in all proportions in boiling absolute alcohol, which deposits most of it on cooling, quite insoluble in ether and in the fixed and volatile oils, and possessed of the property of reddening litmus and of neutralizing the alkalies. Its ultimate constituents are carbon, oxygen, and hydrogen. M. Quevenne found it, when given to dogs, to occasion vomiting and much embarrassment in respiration, and in large quantities to destroy the animal. Dissection exhibited evidences of inflammation of the lungs, and frothy mucus was found in the stomach, œsophagus, and superior portion of the trachea, showing the tendency of this substance to increase the mucous secretion, and explaining in part the beneficial influence of seneka in croup. (*Journ. de Pharm.* xxii. 449 and xxiii. 227.)

From the experiments of M. Quevenne it also appears, that seneka yields its virtues to water, cold or hot, and to boiling alcohol; and that the extracts obtained by means of these liquids have the sensible properties of the root. But, under the influence of heat, a portion of the acrid principle unites with the colouring matter and coagulated albumen, and thus becomes insoluble in water; and the decoction, therefore, is not so strong as the infusion, if time is allowed, in the formation of the latter, for the full action of the men-

struum. If it be desirable to obtain the virtues of the root in the form of an extract, the infusion should be prepared on the principle of displacement; as it is thus most concentrated, and consequently requires less of the injurious influence of heat in its evaporation. In forming an infusion of seneka, the temperature of the water, according to M. Quevenne, should not exceed 104° F. (*Ibid.*)

The roots of the *Panax quinquefolium* or ginseng are frequently mixed with the seneka, but are easily distinguishable by their shape and taste.

Medical Properties and Uses. Seneka is a stimulating expectorant and diuretic, and in large doses proves emetic and cathartic. It appears indeed to excite more or less all the secretions, proving occasionally diaphoretic and emmenagogue, and increasing the flow of saliva. Its action, however, is more especially directed to the lungs; and its expectorant virtues are those for which it is chiefly employed. It was introduced into practice about a century ago by Dr. Tennant of Virginia, who recommended it as a cure for the bite of the rattlesnake and in various pectoral complaints. As an expectorant it is employed in cases not attended with inflammatory action, or in which the inflammation has been in great measure subdued. It is peculiarly useful in chronic catarrh, humoral asthma, the secondary stages of croup, and in peripneumonia notha after sufficient depletion. By Dr. Archer of Maryland it was recommended in the early stages of croup; but under these circumstances it is now seldom given unless in combination with squill and an antimonial, as in the *Syrupus Scillæ Compositus*. Employed so as to purge and vomit it has proved useful in rheumatism; and some cases of dropsy are said to have been cured by it. Amenorrhœa also is among the complaints for which it has been recommended.

The dose of powdered seneka is from ten to twenty grains; but the form of decoction is that in which the medicine is most conveniently administered. (See *Decoctum Senegæ*.) There is an officinal syrup; and an extract and tincture may be prepared, though neither is much employed.

CASSIA. See CASSIA FISTULA.

The plants which yield senna belong to the genus *Cassia*, of which several species contribute to furnish the drug. These were confounded together by Linnæus in a single species, which he named *Cassia Senna*. Since his time the subject has been more thoroughly investigated, especially by *Delile*, who accompanied the French expedition to Egypt, and had an opportunity of examining the plant in its native country. Botanists at present distinguish at least three species, the *C. acutifolia*, *C. obovata*, and *C. elongata*, as the sources of commercial senna; and it is probable that two others, the

C. lanceolata of Forskhal and *C. Æthiopica* of Guibourt, contribute towards it. The first three are recognised by the U. S. Pharmacopœia.

1. *Cassia acutifolia*. Delile, *Flore d'Égypte*, lxxv. tab. 27. f. 1. This is a small undershrub, from two to three feet high, with a straight, woody, branching, whitish stem. The leaves are alternate and pinnate, with glandless footstalks, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, oval lanceolate, acute, oblique at their base, nerved, from half an inch to an inch in length, and of a yellowish-green colour. The flowers are yellow, and arranged in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and divided into six or seven cells, each containing a hard, heart-shaped, ash-coloured seed. The *C. acutifolia* grows wild in great abundance in Upper Egypt near Sienne, in Nubia, Sennaar, and probably in other parts of Africa, having similar qualities of soil and climate. This species furnishes the greater part of that variety of senna, known in commerce by the title of Alexandria senna.

2. *Cassia obovata*. Colladon, *Monographie des Casses*, p. 92. tab. 15. fig. a.; De Cand., *Prodrom.*, ii. 492. The stem of this species is rather shorter than that of the *C. acutifolia*, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate, in other respects similar to those of the preceding species. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown colour, and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. The *C. obtusata* of Hayne, with obovate, truncated emarginate leaflets, is probably a mere variety of this species. The plant, which according to Merat is annual, grows wild in Syria, Egypt, and Senegambia; and is said to have been cultivated successfully in Italy, Spain, and the West Indies. It yields the variety of senna called in Europe Aleppo senna, and contributes to the packages of the Alexandrian.

3. *Cassia elongata*. Lemaire, *Journ. de Pharm.* vii. 345; Fée, *Journ. de Chim. Med.* vi. 232. This name was conferred by M. Lemaire upon the plant from which the India senna of commerce is derived. The botanical description was completed by M. Fée, from dried specimens of the leaves and fruit found by him in unassorted parcels of this variety of senna. Dr. Wallich has subsequently succeeded in raising the plant from seeds found in a parcel of senna taken to Calcutta from Arabia; and it has been described by Dr. Royle, Wight & Arnott, and Dr. Lindley. As usually grown, it is annual; but with care it may be made to live through the year, and then assumes the character of an under-shrub. It has an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lanceolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inwards so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from an inch to twenty lines. The petioles are without glands; the stipules minute, spreading, and semi-hastate. The flowers are bright yellow, and arranged in axillary and terminal racemes, rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the apex, and an inch and a half long by somewhat more than half an inch broad. It is

inferred, from the sources whence the variety of senna which this plant furnishes is brought, that it grows in the southern parts of Arabia. It is said also to grow in the interior of India, and is at present cultivated at Tinnevely for medical use.

Besides the three officinal species above described, the *C. lanceolata* of Forskhal, found by that author growing in the deserts of Arabia, is admitted by Lindley and others as a distinct species. Some difference, however, of opinion exists as to the justice of its claims to this rank. De Candolle considered it only a variety of the *C. acutifolia*, from the ordinary form of which it differs chiefly in having leaflets with glandular petioles; and, as Forskhal's description was prior to that of Delile, he designates the species by the name of *C. lanceolata*; and his example was followed by the London College. Forskhal's plant has been supposed by some to be the source of the India and Mocha senna; but the leaflets in this variety are much longer than those of the *C. lanceolata*, from which the plant differs also in having no gland on the petiole. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of *Abuarish*, whence it is taken by the Arabs to Mecca and Jedda. This is probably the *C. lanceolata* of Forskhal.

The *Cassia Æthiopica* of Guibourt (*C. ovata* of Merat), formerly confounded with the *C. acutifolia*, is considered by Dr. Lindley as undoubtedly a distinct species. It grows in Nubia, Fezzan to the south of Tripoli, and probably, according to Guibourt, throughout Ethiopia. It is from this plant that the *Tripoli senna* of commerce is derived.*

Commercial History. Several varieties of this valuable drug are known in commerce. Of these we receive three only in America, the Alexandria, the Tripoli, and the India senna.

1. *Alexandria Senna.* Though the name of this variety is derived from the Egyptian port at which it is shipped, it is in fact gathered very far in the interior of the country. The Alexandria senna does not consist exclusively of the product of one species of Cassia. The history of its preparation is not destitute of interest. The senna plants of Upper Egypt yield two crops annually, one in spring and the other in autumn. They are gathered chiefly in the country beyond Sienne. The natives cut the plants, and having dried them in the sun, strip off the leaves and pods, which they pack in bales, and send to Boulac, in the vicinity of Cairo, the great entrepot for this article of Egyptian commerce. This senna from Upper Egypt, consisting chiefly though not exclusively of the product of the *C. acutifolia*, is here mixed with the leaflets of the *C. obovata*, brought from other parts of Egypt, and even from Syria, with the leaves of the *Cynanchum olexfolium* (*C. Argel* of Delile), known commonly by the name of *argel* or *arguel*,

* The following is the botanical description of the two species last mentioned, not hitherto officinally recognised.

1. *C. lanceolata.* Forskhal; Lindley, *Flor. Med.* p. 259. "Leaflets in four or five pairs, never more; oblong, and either acute or obtuse, not at all ovate or lanceolate, and perfectly free from downiness even when young; the petioles have constantly a small round brown gland a little above the base. The pods are erect, oblong, tapering to the base, obtuse, turgid, mucronate, rather falcate, especially when young, at which time they are sparingly covered with coarse scattered hairs." (Lindley.)

2. *C. Æthiopica.* Guibourt, *Hist. Ab. des Drogue, &c.* ii. 219; Lindley, *Flor. Med.* p. 259. The plant is about eighteen inches high. The footstalks have a gland at the base and another between each pair of leaflets. There are from three to five pairs of leaflets, which are pubescent, oval lanceolate, from seven to nine lines in length and three or four in breadth, rather shorter and less acute than those of *C. acutifolia*. The legume is flat, smooth, not reniform, rounded, from eleven to fifteen lines long, with from three to five seeds.

and sometimes with those of the *Tephrosia Apollinea* of De Candolle, a leguminous plant growing in Egypt and Nubia. According to M. Royer, the proportions in which the three chief constituents of this mixture are added together, are five parts of the *C. acutifolia*, three of the *C. obovata*, and two of *Cynanchum*. Thus prepared, the senna is again packed in bales, and transmitted to Alexandria. This commercial variety of senna is often called in the French pharmaceutic works *séné de la palthe*, a name derived from an impost formerly laid upon it by the Ottoman Porte.

If a parcel of Alexandria senna be carefully examined, it will be found to consist of the following ingredients:—1. The leaflets of the *C. acutifolia*, characterized by their acute form, and their length almost always less than an inch; 2. the leaflets of the *C. obovata*, known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; 3. the pods, broken leafstalks, flowers, and fine fragments of other parts of one or both of these species; 4. the leaves of the *Cynanchum oleæfolium*, which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter colour, and the regularity of their base. In this last character they strikingly differ from the genuine senna leaflets, which, from whatever species derived, are always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than the other, and at a different angle. The discrimination between this and the other ingredients is a matter of some consequence, as the *cynanchum* must be considered an adulteration. It is said by the French writers to occasion hypercatharsis and much irritation of the bowels; but was found by Christison and Mayer to occasion griping, and severe protracted nausea, with little purgation. The flowers and fruit of the *Cynanchum* are also often present, the former of a white colour, and in small corymbs, the latter an ovoid follicle rather larger than an orange seed. Besides the above constituents of Alexandria senna, it occasionally contains leaflets of genuine senna, much longer than those of the *acutifolia* or *obovata*, equalling in this respect the *cynanchum*, which they also somewhat resemble in form. They may be distinguished however by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their base. They are probably the product of the *C. elongata* or *C. lanceolata*, and may be brought to Egypt from Arabia. The leaflets and fruit of *Tephrosia Apollinea*, which are an occasional impurity in this variety of senna, may be distinguished, the former by their downy surface, their obovate-oblong, emarginate shape, their parallel unbranched lateral nerves, and by being usually folded longitudinally; the latter, by its dimensions, being from an inch to an inch and a half long and only two lines broad. The Alexandria senna sometimes comes to our market with very few leaves of the obovate senna and *Cynanchum*, and is then probably a portion of the product brought directly to Alexandria from Upper Egypt, without having undergone any intermixture at Boulac or other intervening place. In Europe, this senna is said to have been sometimes adulterated with the leaflets of the *Colutea arborescens* or bladder senna, and the leaves of *Coriaria myrtifolia*, a plant of Southern Europe, said to be astringent and even poisonous. An account of the former of these plants is given in the Appendix. The leaflets of the *Coriaria* are ovate lanceolate, grayish-green with a bluish tint, and are readily known, when not too much broken up, by their strongly marked midrib, and two lateral nerves running from the base nearly to the summit. They are chemically distinguished by giving

a whitish precipitate with solution of gelatin, and a bluish-black one with the sesquisalts of iron, proving the presence of tannin. Their poisonous properties are denied by Peschier.

2. *Tripoli Senna*. It has been customary in England and this country to consider the Tripoli senna as very impure; and Paris expressly states, that it contains a much larger proportion than the Alexandrian of cynanchum and other adulterations. This, however, is a mistake, which has probably arisen from the inferior price commanded by this variety; and it is not uncommon to class indiscriminately together under this name all the least valuable parcels of the drug. The fact is, that the genuine Tripoli senna consists in general exclusively of the leaflets of one species, which was formerly considered as a variety of the *C. acutifolia*, but is now admitted to be distinct, and named *C. Æthiopica*. The leaflets, however, are much broken up; and it is probably on this account that the variety is less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets, moreover, are shorter, less acute, thinner, and more fragile than those of the *C. acutifolia* in Alexandria senna; and their nerves are much less distinct. The general opinion at one time was, that it was brought from Sennaar and Nubia to Tripoli in caravans; but it is reasonably asked by M. Fée, how it could be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert. It is probably collected in Fezzan, immediately south of Tripoli, and brought to that town for exportation.

3. *India Senna*. This variety is in Europe sometimes called Mocha senna, probably because obtained originally from that port. It derives its name of India senna from the route by which it reaches us. Though produced in Arabia, it is brought to this country and Europe from Calcutta, Bombay, and possibly other ports of Hindostan. It consists of the leaflets of the *Cassia elongata*, with some of the leafstalks and pods intermixed. The eye is at once struck by the great length and comparative narrowness of the leaflets, so that no difficulty can be experienced in distinguishing this variety. The pike-like shape of the leaflet has given rise to the name of *séné de la pique*, by which it is known in French Pharmacy. Many of the leaflets have a yellowish, dark-brown, or blackish colour, probably in consequence of exposure after collection; and this variety has in mass a dull tawny hue which is not found in the others. It is generally considered inferior in purgative power.

A variety of India senna has recently been introduced into England, which is the produce of Hindostan, being cultivated at Tinnevelly, and probably other places in the South of the Peninsula. The plant was originally raised from seeds obtained from the Red Sea, and is believed to be the same as that from which the common India senna is derived. The drug is exported from Madras to England, where it is known by the name of *Tinnevelly senna*. It is a very fine, unmixed variety, consisting of unbroken leaflets, from one to two or more inches in length, and sometimes half an inch in their greatest breadth, thin, flexible, and of a fine green colour. It is yet scarcely known in the United States, but is said to be rapidly displacing other kinds of senna in some parts of Great Britain.

Commercial senna is prepared for use by picking out the leaflets, and rejecting the leafstalks, the small fragments, and the leaves of other plants. The pods are also rejected by some apothecaries; but they possess the cathartic virtue to a considerable extent, though said to be milder than the leaves.

Properties. The odour of senna is faint and sickly; the taste slightly bitter, sweetish, and nauseous. Water and alcohol extract its active principles. The leaves are said to yield about one-third of their weight to boiling water. The infusion is of a deep reddish-brown colour, and preserves the odour and taste of the leaves. When exposed to the air for a short time, it deposits a yellowish insoluble precipitate, supposed to result from the union of extractive matter with oxygen. The nature of this precipitate, however, is not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues are impaired. To diluted alcohol it imparts the same reddish-brown colour as to water; but rectified alcohol and ether digested upon the powdered leaves become of a deep olive-green. The analysis of senna by MM. Lassaigne and Feneulle furnished the following results. The leaves contain—1. a peculiar principle called cathartin, 2. chlorophylle or the green colouring matter of leaves; 3. a fixed oil; 4. a small quantity of volatile oil; 5. albumen; 6. a yellow colouring matter; 7. mucilage; 8. salts of the vegetable acids, viz. malate and tartrate of lime and acetate of potassa; and 9. mineral salts. The pods are composed of the same principles, with the exception of the chlorophylle, the place of which is supplied by a peculiar colouring matter. (*Journ. de Pharm.* vii. 548 and ix. 58.) Of these constituents, the most interesting and important is the *cathartin*, which is said to be the active principle of senna, and derived its name from this circumstance. It is an uncrystallizable substance, having a peculiar smell, a bitter, nauseous taste, and a reddish yellow colour; is soluble in every proportion in water and alcohol, but insoluble in ether; and in its dry state attracts moisture from the air. It is prepared in the following manner. To a filtered decoction of senna the solution of acetate of lead is added; and the precipitate which forms is separated. A stream of hydrosulphuric acid (sulphuretted hydrogen) is then made to pass through the liquor in order to precipitate the lead, and the sulphuret produced is removed by filtration. The liquid is now evaporated to the consistence of an extract; the product is treated with rectified alcohol; and the alcoholic solution is evaporated. To the extract thus obtained sulphuric acid diluted with alcohol is added, in order to decompose the acetate of potassa which it contains; the sulphate of potassa is separated by filtration; the excess of sulphuric acid by the acetate of lead; the excess of acetate of lead by hydrosulphuric acid; and the sulphuret of lead by another filtration. The liquid being now evaporated yields cathartin. The claims of this substance to be the purgative principle of senna are not universally admitted. Christison states, that what he obtained on applying the process to carefully picked Alexandria senna, had no effect on a healthy adult.

Incompatibles. Many substances afford precipitates with the infusion of senna; but it by no means follows that they are all medicinally incompatible; as they may remove ingredients which have no influence upon the system, and leave the active principles unaffected. Cathartin is precipitated by the infusion of galls and probably other astringents, and by the solution of subacetate of lead. The acetate of lead and tartarized antimony, which disturb the infusion of senna, have no effect upon the solution of this principle.

Medical Properties and Uses. Senna was first used as a medicine by the Arabians. It was noticed in their writings so early as the ninth century; and the name itself is Arabic. It is a prompt, efficient, and very safe purgative, well calculated for fevers and febrile complaints, and other cases in which a decided but not violent impression is desired. An objection some-

times urged against it is that it is apt to produce severe griping pain in the bowels. This effect, however, may be obviated by combining with the senna some aromatic and some one of the alkaline salts, especially the bitartrate of potassa, tartrate of potassa, or sulphate of magnesia. The explanation which attributes the griping property to the oxidized extractive, and its prevention by the neutral salts to their influence in promoting the solubility of this substance, is not entirely satisfactory. The purgative effect of senna is considerably increased by combination with bitters; a fact which was noticed by Cullen, and has been abundantly confirmed by the experience of others. The decoction of guaiac is said to exert a similar influence. The dose of senna in powder is from half a drachm to two drachms; but its bulk renders it of inconvenient administration; and it is not often prescribed in this state. Besides, the powder is said to undergo decomposition, and to become mouldy on exposure to a damp air. The form of infusion is almost universally preferred. (See *Infusum Sennæ*.) The medicine is also used in the forms of confection, tincture, and syrup; and a fluid extract, though not officinal, is sometimes employed in this city. A formula for the fluid extract will be given under *Syrupus sennæ*, in the second part of this work.

Senna taken by nurses is said to purge suckling infants, and an infusion injected into the veins operates as a cathartic.

ARISTOLOCHIA. *Sex. Syst.* Gynandria Hexandria.—*Nat. Ord.* Aristolochiaceæ.

Gen. Ch. Calyx none. Corolla one-petaled, ligulate, ventricose at the base. Capsule six-celled, many-seeded, inferior. *Willd.*

Numerous species of *Aristolochia* have been employed in medicine. The roots of all of them are tonic and stimulant, and from their supposed possession of emmenagogue properties, have given origin to the name of the genus. The *A. Clematitis*, *A. longa*, *A. rotunda*, and *A. Pistolochia*, are still retained in many officinal catalogues of the continent of Europe, where they are indigenous. The root of the *A. Clematitis* is very long, cylindrical, as thick as a goose quill or thicker, variously contorted, beset with the remains of the stems and radicles, of a grayish-brown colour, a strong peculiar odour, and an acrid bitter taste; that of the *A. longa* is spindleshaped, from a few inches to a foot in length, of the thickness of the thumb or more, fleshy, very brittle, grayish externally, brownish-yellow within, bitter, and of a strong disagreeable odour when fresh; that of the *A. rotunda* is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odour and taste; that of the *A. Pistolochia*

consists of numerous slender yellowish or brownish fibres attached to a common head, and possessed of an agreeable aromatic odour, with a taste bitter and somewhat acrid. Many species of *Aristolochia* growing in the West Indies, Mexico, and South America, have attracted attention for their medicinal properties, and some, like our own snakeroot, have acquired the reputation of antidotes for the bites of serpents. In the East Indies, the *A. Indica* is employed for similar purposes with the European and American species; and the Arabians are said by Forskhal to use the leaves of the *A. sempervirens* as a counter-poison. We have within the limits of the United States six species, of which four—the *A. Serpentina*, *A. hirsuta*, *A. hastata*, and *A. reticulata*—contribute to furnish the snakeroot of the shops, though one only, the *A. Serpentina*, is admitted into the Pharmacopœia.

Aristolochia Serpentina. Willd. *Sp. Plant.* iv. 159; Bigelow, *Am. Med. Bot.* iii. 82; Barton, *Med. Bot.* ii. 41. This species of *Aristolochia* is an herbaceous plant with a perennial root, which consists of numerous, slender fibres proceeding from a short horizontal caudex. Several stems often rise from the same root. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently of a reddish or purple colour at the base. The leaves are oblong cordate, acuminate, entire, of a pale yellowish-green colour, and supported on short petioles at the joints of the stem. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downwards so as nearly to bury the flower in the earth or decayed leaves. There is no calyx. The corolla is of a purple colour, monopetalous, tubular, swelling at the base, contracted and curved in the middle, and terminating in a labiate border with lanceolate lips. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is roundish, divided into six parts, and supported by a short fleshy style upon an oblong, angular, hairy, inferior germ. The fruit is an hexangular, six-celled capsule, containing several small flat seeds.

The plant grows in rich, shady woods, throughout the Middle, Southern, and Western States, abounding in the valley of the Ohio, and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania and Virginia, in Ohio, Indiana, and Kentucky, and is brought to the eastern markets chiefly by the route of Wheeling and Pittsburg. As it reaches Philadelphia, it is usually in bales containing about one hundred pounds, and is often mixed with the leaves and stems of the plant, and with dirt from which it has not been properly cleansed at the time of collection.

A. hirsuta. Muhlenberg, *Catalogue*, p. 81; Bridges, *Am. Journ. of Pharm.* xiv. 121. In Muhlenberg's Catalogue this species was named without being described; and botanists, supposing from the name, that it was identical with the *A. tomentosa*, have generally confounded the two plants. But they are entirely distinct. A description of the *A. hirsuta* in the handwriting of Muhlenberg, and a labeled specimen of the plant, in the possession of the Academy of Natural Sciences of this city, have been found to correspond with a dried specimen received by one of the authors of this work from Virginia. The *A. tomentosa* is a climbing plant, growing in Louisiana on the banks of the Mississippi, ascending to the summit of the highest trees. A plant in the garden of the author has a thick creeping root, entirely different in shape from that of the officinal species, though possessed of an analogous odour. The *A. hirsuta* has a root like that of

the *A. Serpentaria*, consisting of a knotty caudex, sending out numerous slender simple fibres, sometimes as much as six inches in length. From this arise several jointed, flexuose, pubescent stems, less than a foot high, with one or two pubescent bractes, and several large roundish cordate leaves, of which the lower are obtuse, the upper abruptly acuminate, and all pubescent on both sides and at the margin. From the joints near the root originate from one to three solitary peduncles, each bearing three or four leafy bractes and one flower. The peduncles, bractes, and corolla are all hairy. This species grows in Virginia, and probably other parts of the Western and Southern States. There is reason to believe that it contributes to afford the serpentaria of commerce, as its leaves, at one time mistaken for those of *A. tomentosa*, have been found in bales of the drug.

A. hastata. Nuttall, *Gen. of N. Am. Plants*, p. 200.—*A. sagittata*. Muhl. *Catal.* This species, if indeed it can be considered a distinct species, differs from the *A. Serpentaria* in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in Carolina, and elsewhere. Its root scarcely differs from that of the officinal plant, and is frequently mixed with it, as proved by the presence of the characteristic leaves of the *A. hastata* in the parcels brought into market. (See *Journ. of the Phil. Col. of Pharm.* i. 264.)

A. reticulata. Nuttall; Bridges, *Am. Journ. of Pharm.* xiv. 118. This plant was probably first observed by Mr. Nuttall, as a specimen labeled "*A. reticulata*, Red river," in the handwriting of that botanist, is contained in the Herbarium of the Academy of Natural Sciences of Philadelphia. From this specimen, as well as from others found in sufficient perfection in parcels of the drug recently brought into market, a description was drawn up and published by Dr. Robert Bridges in the *American Journ. of Pharmacy*. From a root, similar to that of the *A. Serpentaria*, numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older stems are slightly villous, the young densely pubescent. The leaves, which stand on very short villous petioles, are round or oblong cordate, obtuse, reticulate, very prominently veined, and villose on both sides, especially upon the veins. From the lower joints of the stem four or five hairy, jointed peduncles proceed, which bear small leafy villous bractes at the joints, and several flowers on short pedicels. The flowers are small, purplish, and densely pubescent, especially at the base and on the germ. The hexangular capsule is deeply sulcate. This species grows on the Red river in Arkansas, and probably in the Indian Territory to the west of that state, but its geographical range has not been ascertained.

Bales of a new variety of serpentaria have recently been brought to Philadelphia, which is certainly the product of this species, as specimens of all parts of the plant have been found in the bales, and the roots, which differ somewhat from those before known, are homogeneous in character. One of these bales was brought from New Orleans, and was said to have come down the Red river, and to have been collected by the Indians. The chief difference between this and ordinary Virginia snakeroot is in the size of the radicles, which are much thicker and less interlaced in the new variety. Each root has usually a considerable portion of one or more stems attached to the caudex. The colour is yellowish. The odour and taste are scarcely, if at all distinguishable from those of common serpentaria; and there can be little doubt that the root will be found equally effectual as a medicine.

Properties. Virginia snakeroot, as found in the shops, is in tufts of long, slender, frequently interlaced, and brittle fibres, attached to a short, contorted,

knotty head or caudex. The colour, which in the recent state is yellowish, becomes brown by time. That of the powder is grayish. The smell is strong, aromatic, and camphorous; the taste warm, very bitter, and also camphorous. The root yields all its virtues to water and alcohol, producing with the former a yellowish-brown infusion, with the latter a bright greenish tincture, which is rendered turbid by the addition of water. Chevallier found in the root, volatile oil, a yellow bitter principle soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Bucholz obtained from 1000 parts, 5 of a green fragrant volatile oil, 28·5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of lignin, and 144·5 of water. The active ingredients are probably the volatile oil, and the yellow bitter principle of Chevallier, which that chemist considers analogous to the extract of quassia called *quassin* by Dr. Thomson. The volatile oil passes over with water in distillation, rendering the liquid milky, and impregnating it with the peculiar odour of the root. Dr. Bigelow states that the liquid on standing deposits around the edges of its surface small crystals of camphor.

The roots of the *Spigelia Marilandica* are sometimes found associated with the serpentaria. They may be distinguished by the absence of the bitter taste, and, when the stem and foliage are attached, by the peculiar character of these parts of the plant. (See *Spigelia*.)

Medical Properties and Uses. Serpentaria is a stimulant tonic, acting also as a diaphoretic or diuretic, according to the mode of its application. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomiting and dysenteric tenesmus. It is admirably adapted to the treatment of typhoid fevers, whether idiopathic or symptomatic, when the system begins to feel the necessity for support, but is unable to bear active stimulation. In exanthematous diseases in which the eruption is tardy or has receded, and the grade of action is low, it is thought to be useful by promoting the cutaneous affection. It has also been highly recommended in intermittent fevers; and though itself generally inadequate to the cure of the complaint, often proves serviceable as an adjunct to Peruvian bark or the sulphate of quinia. With the same remedies it is frequently associated in the treatment of typhous diseases. It is sometimes given in dyspepsia, and is employed as a gargle in malignant sorethroat.

The dose of the powdered root is from ten to thirty grains; but the infusion is almost always preferred. (See *Infusum Serpentariæ*.) The decoction or extract would be an improper form, as the volatile oil, upon which the virtues of the medicine partly depend, is dissipated by boiling.

SESAMUM. *Sex. Syst.* Didynamia Angiospermia.—*Nat. Ord.* Bignoniæ, *Juss.*; Pedaliaceæ, *R. Brown, Lindley*.

Gen. Ch. *Calyx* five-parted. *Corolla* bell-shaped, five-cleft, with the lower lobe largest. *Stamens* five, the fifth a rudiment. *Stigma* lanceolate. *Capsule* four-celled. *Willd.*

Though the *Sesamum orientale* has been indicated by the United States Pharmacopœia as the medicinal plant, there is reason to believe that the *S. Indicum* is the one cultivated in our Southern States; at least we have found plants raised in Philadelphia from seeds obtained from Georgia, to have the specific character of the latter, as given by Willdenow.

Sesamum orientale. Willd. *Sp. Plant.* iii. 358; Rheed. *Hort. Malab.* ix. 54. "Leaves ovate, oblong, entire."

Sesamum Indicum. Willd. *Sp. Plant.* iii. 359; Curtis, *Bot. Mag.* vol. xli. t. 1688. "Leaves ovate-lanceolate, the inferior three-lobed, the superior undivided: Stem erect."

The benne plant of our Southern States is annual, with a branching stem, which rises four or five feet in height, and bears opposite, petiolate leaves, varying considerably in their shape. Those on the upper part of the plant are ovate-lanceolate, irregularly serrate, and pointed; those near the base three-lobed and sometimes ternate; and lobed leaves are not uncommon at all distances from the ground. The flowers are of a reddish-white colour, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, containing small, oval, yellowish seeds.

These two species of *Sesamum* are natives of the East Indies, and have been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the Negroes to our Southern States, where, as well as in the West Indies, one or both species are now cultivated to a considerable extent. It has been found that the plant above described will grow vigorously in the gardens so far north as Philadelphia.

The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which, as well as the leaves of the plant, has been introduced into the secondary catalogue of our national Pharmacopœia.

1. *Oil of Benne*. This is inodorous, of a bland sweetish taste, and will keep very long without becoming rancid. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It was known to the ancient Persians and Egyptians, and is highly esteemed by the modern Arabs and other people of the East, both as food, and as an external application to promote softness of the skin. Like olive oil, it is laxative in large doses.

2. *Leaves*. These abound in a gummy matter, which they readily impart to water, forming a rich bland mucilage, much used in the Southern States as a drink in various complaints to which demulcents are applicable, as in cholera infantum, diarrhœa, dysentery, catarrh, and affections of the urinary passages. The remedy has attracted some attention further northward, and has been employed with favourable results by physicians in Philadelphia. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. In their dried state they should be introduced into hot water. The leaves also serve for the preparation of emollient cataplasms. W.

SEVUM. *U.S., Lond., Ed.**Suet.*

"The prepared suet of *Ovis Aries*." *U.S.* "*Ovis Aries. Sevum.*" *Lond.* "Fat of *Ovis Aries*." *Ed.*

Off. Syn. ADEPS OVILLUS PRÆPARATUS. *Dub.*

Suif, Graisse de mouton, *Fr.*; Hammelstalg, *Germ.*; Grasse duro, *Ital.*; Sebo, *Span.*

Suet is the fat of the sheep taken chiefly from about the kidneys. It is prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water.

Mutton-suet is of a firmer consistence, and requires a higher temperature for its fusion than any other animal fat. It is very white, sometimes brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposits it upon cooling. It consists, according to Chevreul, of stearin, olein, and a small proportion of hircin. For an account of the two first mentioned principles, the reader is referred to the article *Adeps*. *Hircin* is a liquid like olein, from which it differs in being much more soluble in alcohol, and in yielding *hircic acid* by saponification.

Suet acquires by time an unpleasant smell, and becomes unfit for pharmaceutical purposes. It is employed exclusively to give a proper consistence to ointments and plasters. *W.*

SIMARUBA. *U.S., Lond., Ed.**Simaruba.*

Off. Syn. QUASSIA SIMARUBA. Cortex radicis. *Dub.*

Encorce de simarouba, *Fr.*; Simarubarinde, *Germ.*; Corteccia di simaruba, *Ital.*; Corteza de simaruba, *Span.*

QUASSIA. See QUASSIA.

Quassia Simaruba. Willd. *Sp. Plant.* ii. 568; Woodv. *Med. Bot.* p. 569. t. 203.—*Simaruba officinalis*, De Cand. *Prodrom.* i. 733.—*S. amara*, Aublet; Lindley, *Flor. Med.* p. 207. As this plant is unisexual, it belongs to the genus *Simaruba* of De Candolle and Lindley, those only being placed by these botanists in the genus *Quassia* which are hermaphrodite. But as the Linnean arrangement was adhered to in the case of the *Quassia excelsa*, we continue to adhere to it in relation to this plant. (See *Quassia*.) It is a tree of considerable height and thickness, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked here and there with broad yellow spots. The leaves are alternate and abruptly pinnate, with a naked petiole to which the leaflets are alternately attached by short footstalks. The leaflets are nearly elliptical, on the upper surface smooth and of a deep green colour, on the under whitish. The flowers are of a yellow colour, and are disposed in long axillary panicles. In some descriptions they are stated to be monœcious, in others diœcious. According to Dr. Wright, the female flowers are never found in Jamaica on the same tree with the male. The number of stamens is ten.

The tree is found in the West Indies and Guyana. In Jamaica it is called

the mountain damson. The *Simaruba amara* of Aublet, which grows in Guyana, and has generally been considered identical with the *Q. Simaruba*, is believed by Hayne to be a distinct species, the Jamaica plant having diœcious, while this has monœcious flowers. The bark of the root is the part employed, the wood itself being nearly tasteless and inert.

Simaruba bark is in long pieces, some inches in breadth, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow colour, rough, warty, and marked with transverse ridges, internally of a pale yellow. It is without smell, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to M. Morin, are a bitter principle, supposed by him to be identical with *quassin*, a resinous matter, a volatile oil having the odour of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, malate and oxalate of lime, some mineral salts, oxide of iron, silica, ulmin, and lignin.

Medical Properties and Uses. *Simaruba* possesses the same tonic properties as other simple bitters, and may be employed for the same purposes. In large doses it is said to purge and vomit. It was introduced into France in the year 1713 from Guyana, where it had previously been used as a remedy for dysentery. In the treatment of this disease and of obstinate diarrhœa it afterwards obtained much credit in Europe; but Cullen was right in denying to it any specific control over these complaints. It operates simply as a tonic; and, though it may be occasionally beneficial in relaxed and debilitated states of the alimentary canal, it would do much harm if indiscriminately prescribed in dysenteric cases.

On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. (See *Infusum Simarubæ*.) The dose is from a scruple to a drachm.

Sinapis nigra. Willd. *Sp. Plant.* iii. 555; Woodv. *Med. Bot.* p. 403. t. 146. Common or black mustard is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate, and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally toothed; those higher on the stem are smooth and less lobed; and the uppermost are entire, narrow, smooth and dependent. The flowers are small, yellow, with a coloured calyx, and stand closely together upon peduncles at the upper part of the branches.

The pods are smooth, erect, nearly parallel with the branches, quadrangular, furnished with a short beak, and occupied by numerous seeds.

Sinapis alba. Willd. *Sp. Plant.* iii. 555; Smith, *Flor. Brit.* 721. The white mustard is also an annual plant. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged with stiff hairs on both sides, and of a pale green colour. The flowers are in racemes, with yellow petals, and linear, green, calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

Both plants are natives of Europe and cultivated in our culinary gardens; and the *S. nigra* has become naturalized in some parts of this country. Their flowers appear in June. The seeds are kept in the shops both whole and in the state of very fine powder, as prepared by the manufacturers for the table.

The *black mustard seeds* are small, globular, of a deep brown colour, slightly rugose on the surface, and internally yellow. In the entire state they are inodorous, but have a distinct smell in powder, and when rubbed with water or vinegar exhale a strong pungent odour, sufficient in some instances to excite a flow of tears. Their taste is bitterish, hot, and pungent, but not permanent. The *seeds of the white mustard* are much larger, of a yellowish colour, and less pungent taste. Both afford a yellow powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called *flour of mustard*, or simply *mustard*, and is prepared by crushing and pounding the seeds, and then sifting them; the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. It is often adulterated with wheat flour coloured by turmeric, to which red pepper is added to render the mixture sufficiently hot. The skin of white mustard seeds contains a mucilaginous substance, which is extracted by boiling water. When bruised or powdered, both kinds impart their active properties wholly to water, but in a very slight degree to alcohol. They yield upon pressure a fixed oil, of a greenish-yellow colour, little smell, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seed.

It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, having sulphur among its constituents. Guibourt conjectured, and Robiquet and Boutron proved, that this oil does not pre-exist in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odour in the seeds when bruised in a dry state, and their great pungency when water is added. It seemed very reasonable to suppose that the reaction in this case was similar to that exercised by water upon bitter almonds (see *Amygdala Amara*); and this has been proved to be the fact by the experiments of Simon, Bussy, Boutron, and Frémy. According to M. Bussy, there are two peculiar principles in black mustard seeds, one named by him *myronic acid*, which exists in the seeds in the state of *myronate of potassa*; the other named *myrosyne*, closely analogous in character to the albuminous constituent of almonds called *emulsin*. When water is added to black mustard seed, the myrosyne, acting the part of a ferment, determines a reaction between the water and myronate of potassa, which results in the production of the volatile oil. The same thing happens when any one of the myronates is brought into contact with water and myrosyne. The presence of the last-mentioned principle is essential. Like emulsin, it becomes inoperative when coagulated by heat, alcohol, or the acids; and if black mustard seeds be subjected

to either of these agencies previously to the addition of water, they will yield no volatile oil. The myrosyne, however, sometimes partially recovers its power by continued contact with water. This substance is found also in white mustard seeds, but without the myronate of potassa. If, therefore, white mustard seeds be added to the black in which the myrosyne has been coagulated, the volatile oil will be generated on the application of water. Though closely analogous to emulsin, myrosyne is yet a distinct principle, as its place cannot be supplied by emulsin with the same effect. (*Journ. de Pharm.* xxvi. 39.) Simon obtained results somewhat different from those of M. Bussy. The former chemist succeeded in procuring a peculiar crystalline principle from the seeds, which he called *sinapisin*, and which, upon contact with water and the albuminous principle of the seeds, emitted the odour of the oil of mustard. According to Simon, the emulsin of almonds does not answer the same purpose, because it contains no sulphur, which is an essential constituent of the oil of mustard. The whole subject requires further investigation.

The *volatile oil of mustard* is usually obtained from seeds which have been deprived of their fixed oil by pressure. It is a colourless or pale yellow liquid, rather heavier than water, of an exceedingly pungent odour, and an acrid burning taste. It boils at about 290° ; is slightly soluble in water, and readily so in alcohol and ether; with alkaline solutions yields sulphocyanurets; and, according to Dumas and Pelouze, consists of 49.53 parts of carbon, 5.02 of hydrogen, 11.74 of oxygen, 13.45 of nitrogen, and 20.26 of sulphur. It is the principle upon which black mustard seeds depend for their activity.

White mustard seeds do not yield volatile oil when treated with water; but an acrid fixed principle is developed, which renders these seeds applicable to the same purposes as the other variety. MM. Robiquet and Boutron, who ascertained this fact, concluded that the acrid principle resulted from the reaction of water upon *sulpho-sinapisin* discovered in these seeds by MM. Henry, Jun., and Garot. Their reason for this belief was that mustard, which had been deprived of this ingredient, was incapable of developing the acrid principle. The myrosyne or emulsin is equally essential to the change here, as to that which occurs in black mustard; and the reaction equally fails, if this principle be previously rendered inert by heat, alcohol, or the acids. MM. Boutron and Frémy state that not only the acrid principle of white mustard, but hydrosulphocyanic acid also results from the reaction above explained; and this observation renders still closer the analogy between the changes that take place, upon contact with water, in mustard seeds and bitter almonds. (*Journ. de Pharm.* xxvi. 50.)*

From the above account of the chemical relations of mustard, it is obvious

* As some may desire to push these investigations further, we give the properties of these newly discovered principles, and the modes of procuring them.

Myronic acid is a fixed inodorous substance of a bitter and sour taste, and acid reaction. When obtained separate from its bases, it forms a colourless solution, which by evaporation becomes of a thick consistence like molasses, without crystallizing. It is soluble in water and alcohol, but not in ether; and forms soluble salts with the alkalies, baryta, lime, and the oxides of lead and silver, all of which yield volatile oil of mustard when mixed with an aqueous solution of myrosyne. It contains sulphur, besides carbon, hydrogen, nitrogen, and oxygen. It is obtained from the myronate of potassa by adding to 100 parts of that salt 38 parts of crystallized tartaric acid, concentrating the solution by evaporation, and then adding weak alcohol, which precipitates the bitartrate of potassa, and retains the myronic acid in solution. To obtain *myronate of potassa* from black mustard seeds, the powder, having been dried at 212° , and deprived of its fixed oil by pressure, is treated with strong alcohol in a displacement apparatus, and when thus nearly

that admixture with alcohol or the acids, or the application of a boiling heat, can only have the effect of impairing its medical virtues, and that the best vehicle, whether for external or internal use, is water at common temperatures.

Medical Properties and Uses. Mustard seeds swallowed whole operate as a laxative, and have recently enjoyed great popularity as a remedy in dyspepsia, and in other complaints attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act in some measure by mechanically stimulating the bowels. The bruised seeds or powder, in the quantity of a large teaspoonful, operate as an emetic. Mustard in this state is applicable to cases of great torpor of stomach, especially that resulting from narcotic poisons. It rouses the gastric susceptibility and facilitates the action of other emetics. In smaller quantities it is useful as a safe stimulant of the digestive organs; and, as it is frequently determined to the kidneys, has been beneficially employed in dropsy. Whey made by boiling half an ounce of the bruised seeds or powder in a pint of milk, and straining, is a convenient form for administration. It may be given in the dose of a wineglassful repeated several times a day. But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with a burning pain which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal portion of rye meal or wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus

exhausted of every thing soluble in that liquid, is pressed, and treated with water. The aqueous solution is evaporated, and before it is too much concentrated, weak alcohol is added, which precipitates a glutinous matter. The solution being then carefully evaporated deposits crystals of myronate of potassa, which may be obtained very pure and white by washing the mass with diluted alcohol. This salt is easily crystallizable in fine, large, transparent crystals, is unalterable in the air, very soluble in water, insoluble in pure alcohol, and of a bitter taste.

Myrosyne, when dry, has the character of an albuminous substance. It is soluble in water, forming a viscid solution, which froths when agitated, and is coagulated by heat, alcohol, and the acids. It is obtained by treating white mustard seed with cold water, filtering the solution, evaporating it by a heat not exceeding 100°, and when it is of the consistence of syrup, carefully adding alcohol, which causes a precipitate easily separable by decantation. If this be dissolved in water, and the solution evaporated as before, myrosyne is obtained, though not entirely pure. (*Journ. de Pharm.* xxvi. 39.)

The *sinapisin* of Simon is in brilliant, white, scaly crystals, sublimable by heat, soluble in alcohol, ether, and the fixed and volatile oils, but insoluble in acids and alkalies. To obtain it he exhausted black mustard seed with strong alcohol, distilled off the greater part of the alcohol, treated the residue several times with four or five times its weight of ether, from the ethereal solutions distilled off all the ether, treated the extract again with a smaller quantity of ether so as to leave behind insoluble substances, and repeated this process until the extract formed a perfectly clear solution without residue. The extract was then dissolved in cold strong alcohol, and the solution having been decolorized with animal charcoal, was allowed to evaporate in the air. Simon obtained from 55 pounds of the seeds only 80 grains of crystallized sinapisin. (*Annal. der Pharm.* xxviii. 291.)

Sulpho-sinapisin, the peculiar ingredient of white mustard seed, is white, crystallizable, inodorous, bitter, and soluble in alcohol and water, forming a yellow solution. It was at first thought by M.M. Henry and Garot to be an acid, but they afterwards ascertained that it was neuter. It consists of carbon, hydrogen, nitrogen, oxygen, and sulphur. It may be obtained from white mustard seeds, from which the fixed oil has previously been expressed, by boiling them in water, evaporating the decoction to the consistence of honey, mixing the residue with 6 or 8 times its volume of anhydrous alcohol which precipitates various substances, then distilling off the alcohol, and setting aside the syrupy residue to crystallize. The crystals may be purified by repeated solution and crystallization in alcohol. (Berzelius, *Traité de Chimie*.)

may result. This caution is particularly necessary in cases where the patient is insensible, and the degree of pain can afford no criterion of the sufficiency of the action. The volatile oil, which is powerfully rubefacient and capable of producing speedy vesication, has been considerably used in Germany. For external application as a rubefacient, 30 drops may be dissolved in a fluidounce of alcohol, or 6 or 8 drops in a fluidrachm of almond or olive oil. It has been given internally in colic, two drops being incorporated with a six ounce mixture, and half a fluidounce given for a dose. (See *Am. Journ. of Pharm.* xi. 9.)

SODIUM.

Sodium.

Sodium, *Fr.*; Natronmetall, *Natrium, Germ.*; Sodio, *Ital., Span.*

Sodium is a peculiar elementary body of a metallic nature, forming the radical of the alkali soda. It was discovered by Sir H. Davy in 1807, who obtained it in minute quantity by decomposing the alkali by the agency of galvanic electricity. It was afterwards procured in much larger quantities by Gay-Lussac and Thenard, by bringing the alkali in contact with iron turnings heated to whiteness. The iron became oxidized, and the metallic radical of the soda was liberated. It is now obtained at a much cheaper rate by following the process of Schœdler, which consists in heating, in a large iron bottle, the commercial acetate of soda, previously converted into carbonate and charcoal by ignition, and mixed with a further portion of charcoal.

Sodium is a soft, malleable, sectile solid, of a silver-white colour. It possesses the metallic lustre in a high degree when protected from the action of the air, by which it is quickly tarnished and oxidized. Its sp. gr. is 0.97, fusing point about 200°, equivalent number 23.3, and symbol Na. Its chemical affinities resemble those of potassium, but are by no means so energetic. Like potassium it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on hot water it inflames. In both cases the water is decomposed, hydrogen is liberated, and a solution of soda generated. It combines also with a larger proportion of oxygen than exists in soda, forming a sesquioxide. This oxide is always formed when the metal is burnt in the open air.

Sodium is present in a number of important medicinal preparations, and is briefly described in this place as an introduction to these compounds. Its protoxide only is salifiable, constituting the alkali soda, which, united to acids, gives rise to a numerous class of compounds, called salts of soda. These are characterized by being all soluble in water and not precipitable by any reagent, and by their communicating to the blowpipe flame, a rich yellow colour. Protoxide of sodium consists of one eq. of sodium 23.3, and one of oxygen 8=31.3. United with one eq. of water 9, it forms hydrate of soda (caustic soda), weighing 40.3.

The official combinations containing sodium are chloride of sodium, the solution of chlorinated soda, the acetate, borate, carbonate, bicarbonate, phosphate, and sulphate of soda, and the tartrate of potassa and soda. The description of most of these combinations will immediately follow; while the remainder, being included among the "Preparations," will be noticed, under their respective titles, in the second part of this work. B.

SODÆ ACETAS. U.S., Lond., Dub.

Acetate of Soda.

Terra foliata tartari, *Lat.*; Acétate de soude, *Fr.*; Essigsaures Natron, *Germ.*; Acetato di soda, *Ital.*

Acetate of soda is included among the "Preparations," in the Dublin Pharmacopœia; but more properly in the catalogue of the Materia Medica in those of London and the United States; as it is obtained on a large scale by the manufacturing chemist.

Preparation. The Dublin College obtains this salt by saturating carbonate of soda with distilled vinegar, and evaporating the filtered solution until it attains the sp. gr. 1.276. As the solution cools crystals will form, which must be cautiously dried, and kept in well stopped bottles. In conducting the process, the crystallized carbonate of soda will be found to require about eleven times its weight of distilled vinegar for saturation.

Acetate of soda is prepared by the manufacturers of pyroligneous acid, for the purpose of being decomposed so as to yield strong acetic acid by the action of sulphuric acid. (See *Acidum Pyroligneum*, and *Acidum Aceticum*.) The first step is to add to the impure acid sufficient cream of lime to saturate it. During the saturation a quantity of blackish scum rises, which must be carefully removed. In this way an acetate of lime is formed, which must be decomposed by a strong solution of sulphate of soda. By double decomposition there are formed acetate of soda which remains in solution, and sulphate of lime which precipitates, carrying down with it more or less of the tarry impurities. After the sulphate of lime has completely subsided, the solution of acetate of soda is decanted, and concentrated to a pellicle; when it is transferred to crystallizers, in which it cools and crystallizes in mass. The acetate in this state, is very impure, being black and impregnated with much tar. It is purified by drying, submitting it to the igneous fusion, solution in water, filtration, and repeated crystallizations. Sometimes animal charcoal is used to free the crystals from colour.

Properties, &c. Acetate of soda is a white salt, occurring in amorphous foliated masses, or crystallized in long striated prisms, and possessing a sharp, bitterish, not disagreeable taste. Exposed to the air it effloresces slowly, and loses about forty per cent. of its weight. It is soluble in about three parts of cold water, and in twenty-four of alcohol. The London College is inaccurate in stating that this salt is insoluble in alcohol. Subjected to heat, it undergoes first the aqueous and then the igneous fusion, and is finally decomposed; the residue being a mixture of carbonate of soda and charcoal. By the affusion of sulphuric acid it is decomposed, the acetic acid being liberated, known by its acetous odour, and sulphate of soda formed. The salt should be perfectly neutral to test paper, and not precipitated by chloride of barium, nitrate of silver, or chloride of platinum. The non-action of these tests proves the absence of sulphates, chlorides, and salts of potassa. It consists, when crystallized, of one eq. of acetic acid 51.48, one of soda, 31.3, and six of water 54=136.78.

Medical Properties and Uses. Acetate of soda is diuretic, and possesses generally the same medical properties as the acetate of potassa, to which article the reader is referred. It is, however, more convenient for exhibition than the latter salt, as it is not deliquescent. The dose is from a scruple to two drachms. Its only pharmaceutical use is to yield acetic acid by the action of sulphuric acid, and for this purpose it is employed in the London and United States Pharmacopœias.

B.

SODÆ BORAS. U.S.

Borate of Soda.

Off. Syn. BORAX. *Lond., Ed.*; SODÆ BORAS. BORAX. *Dub.*

Borate de soude, Borax, *Fr.*; Boraxsaures Natron, Borax, *Germ.*; Borace, *Ital.*; Borraz, *Span.*; Boorak, *Arab.*

Borax was known to the ancients, but its chemical nature was first ascertained by Geoffroy in 1732. It exists native, and may be obtained by artificial means. It occurs in small quantities in several localities in Europe, and in Peru in South America; but is found abundantly in certain lakes of Thibet and Persia, from which it is obtained by spontaneous evaporation. The impure borax concretes on the margins of these lakes, and is dug up in lumps, called in commerce *tincal* or *crude borax*. In this state it is in the form of crystalline masses, which are sometimes colourless, sometimes yellowish or greenish, and always covered with an earthy coating, greasy to the touch, and having the odour of soap. The greasy appearance is derived from a fatty matter, saponified by soda. The tincal, thus obtained in the interior, is transferred to the seaports of India, especially Calcutta, from which it is exported to this country packed in chests. Besides Indian tincal, there is another commercial variety of borax, which comes from China, and which is partially refined. Both varieties require to be purified, before being used in medicine or the arts.

Purification. The method of refining borax was originally possessed as a secret by the Venetians and Dutch, but is now practised in several European countries. The process pursued in France, as reported by Robiquet and Marchand, is as follows. The tincal is placed in a large wooden vessel, and covered to the depth of three or four inches with water; in which state it is allowed to remain for five or six hours, being agitated from time to time. Slaked lime is now added, in the proportion of one part to four hundred of the impure salt; and the whole being thoroughly mixed, is allowed to remain at rest till the succeeding day. The salt is next separated by means of a sieve, the crystals being crumbled between the hands, and placed so as to drain. The object of this treatment is to separate the soapy matter, with which the lime forms an insoluble soap; and at the same time sulphate of soda and chloride of sodium are removed, with only a minute loss of the borax. The borax being drained, is next dissolved, by the assistance of heat, in two and a half times its weight of water, and the solution treated with one-fiftieth of its weight of chloride of calcium, and allowed to strain through a coarse bag. The filtration being completed, the liquor is concentrated by heat, and then run into wooden vessels, lined with lead, having the shape of an inverted quadrangular pyramid. If care be taken that the cooling proceeds very gradually, distinct crystals will be obtained, such as are found in commerce; otherwise, crystalline crusts will be formed. The Chinese borax is purified in a similar manner, but being less impure than the common tincal, does not require to be washed.

Preparation of Artificial Borax. Large quantities of borax are now made by the direct combination of native boracic acid with soda. The acid is obtained from certain lagoons in Tuscany, which are spread over a surface of about thirty miles. At present, from these lagoons the enormous quantity of 2,400,000 pounds are annually manufactured. As thus procured, the acid contains from 17 to 20 per cent. of impurities, consisting principally of the sulphates of ammonia, magnesia, lime, and alumina,

muriate of ammonia, chloride of iron, and clay, sand, and sulphur. It is added to saturation to a solution of carbonate of soda, heated by steam, and the liquor, after boiling, is allowed to stand for ten or twelve hours. It is then drawn off into wooden vessels lined with lead, where it crystallizes. The crystals are impure, and are refined by dissolving them in water heated by steam, adding carbonate of soda to the solution, and crystallizing. The merit of introducing the process for obtaining artificial borax belongs to Cartier and Payen, who succeeded in establishing its manufacture in France, notwithstanding the strong prejudice felt against its use.

Properties. Borax is a white salt, generally crystallized in flattened hexahedral prisms terminated by triangular pyramids, and possessing a sweetish, feebly alkaline taste, and an alkaline reaction with test paper. It dissolves in twelve times its weight of cold, and twice its weight of boiling water. Exposed to the air, it effloresces slowly and slightly at the surface of the crystals, which become covered with a white powder. Subjected to a moderate heat it undergoes the aqueous fusion, swells considerably, and finally becomes a dry porous mass, with loss of half its weight. Above a red heat it melts into a limpid liquid, and, after cooling, concretes into a transparent solid, called *glass of borax*, which is very much used as a flux in assays with the blowpipe. Sulphuric acid, added to a saturated solution of the salt, unites with the soda, and precipitates the boracic acid in scaly crystals, known by their property of imparting a green colour to the flame of burning alcohol. According to Dr. Duncan, borax possesses the singular property of converting the mucilage of gum Arabic, of Iceland moss, and salep, into a gelatinous mass, without any adhesive property.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it, called *soluble cream of tartar*, which is sometimes used in medicine. This preparation is made by boiling six parts of cream of tartar and two of borax in sixteen of water for five minutes, allowing the solution to cool, and then filtering to separate some tartrate of lime. Soluble cream of tartar attracts moisture from the air, and is soluble in its own weight of cold, and half its weight of boiling water. A similar preparation may be made by substituting boracic acid for the borax, the proportions being four parts of cream of tartar to one of the acid. This combination is even more soluble than the other. It has not been well ascertained what is the nature of these compounds. Thenard has thrown out the suggestion, that the former consists of two double salts, tartrate of potassa and soda (Rochelle salt), and tartrate of potassa and boracic acid; the acid acting the part of a base; and Berzelius inclines to the opinion, that the latter is a double tartrate of potassa and boracic acid. According to the formula of the Paris Codex, soluble cream of tartar is made with boracic acid. One hundred parts of the acid and 400 of cream of tartar are dissolved in a silver basin, at the temperature of ebullition, in 2400 parts of water. The solution is kept boiling until the greater part of the water is consumed. The fire is then moderated, and the solution continually stirred while the evaporation proceeds. When the matter has become very thick, it is removed by portions, which are flattened in the hand, completely dried by the heat of a stove, reduced to powder, and kept in well stopped bottles.

Composition. Borax consists of two eqs. of boracic acid 69.8, and one of soda 31.3 = 101.1. As ordinarily crystallized it contains ten eqs. of water; but a variety of the salt exists, which crystallizes in octohedrons, and which contains only five eqs. of water. This is obtained in the artificial production of borax, by crystallizing from a concentrated solution at a temperature between 174° and 133°. From the composition of borax in equi-

valents, it is evidently a biborate, though generally called a subborate, on account of its possessing an alkaline reaction. This latter property arises from the feeble neutralizing power of boracic acid, which renders it unable to overcome the alkaline nature of so strong a base as soda.

Medical Properties and Uses. Borax is a mild refrigerant and diuretic. It is supposed also to exercise a specific influence over the uterus, promoting menstruation, facilitating parturition, and favouring the expulsion of the placenta. (Vogt's *Pharmakodynamik*, quoted by Pereira, *Elem. Mat. Med.*) It is strongly recommended by Dr. Daniel Stahl, of Indiana, in dysmenorrhœa occurring in sanguineous constitutions, venesection being premised. He gives it in doses of about nine grains every two hours in a tablespoonful of flaxseed tea, for two days before the time of the expected return of the menses. (*Am. Journ. of Med. Sci.* xx. 536, from *Western Journ. of Med. and Phys. Sci.*) Dr. Duncan quotes Wurzer for asserting that it is the best remedy that can be used in nephritic and calculous complaints, dependent on an excess of uric acid. It probably acts in such cases as an alkali, the soda of the salt neutralizing the acid met with in the stomach or urinary passages, and the boracic acid being set free. The dose is from thirty to forty grains. Cream of tartar, rendered soluble by borax or boracic acid, is a convenient preparation, where it is desirable to administer large quantities of the former salt. Externally its solution is used as a wash in scaly cutaneous eruptions. A solution formed by dissolving a drachm of the salt in two fluidounces of distilled vinegar has been found, both by Dr. Abercrombie and Dr. Christison, an excellent lotion for ringworm of the scalp. Borax is very much used as a detergent in aphthous affections of the mouth in children. When employed for this purpose, it is generally applied in powder, either mixed with sugar in the proportion of one part to seven, or rubbed up with honey. (See *Mel Boracis*.)

SODÆ CARBONAS IMPURA. *Lond.*

Impure Carbonate of Soda.

Off. Syn. SODÆ CARBONAS VENALE. BARILLA. *Dub.*

Soude de commerce, *Fr.*; Rohe Soda, *Germ.*; Soda impura, *Ital.*; Barilla, *Span.*

The impure carbonate of soda intended by the London College, is the artificial carbonate, obtained on a large scale by the manufacturing chemist, which the College deems not quite pure enough for medicinal use. The equivalent preparation of the Dublin College is the impure carbonate obtained by incinerating maritime plants, to which the name *barilla* strictly belongs. The Edinburgh College has very properly dismissed the impure carbonate, as the source from which the apothecary is to obtain the medicinal carbonate by a process of purification; deeming the alkali as manufactured on a large scale to be sufficiently pure. Influenced by the same views the framers of our national Pharmacopœia have never admitted on the officinal list, the impure carbonate of soda.

Although the official names at the head of this article only indicate *barilla*, and the artificial carbonate of soda obtained by chemical means, yet we shall not confine our remarks to these substances, but notice, generally, the sources of the alkali.

Carbonated soda exists as a mineral, and is obtained by incinerating certain plants, and by decomposing sulphate of soda.

Native soda is found chiefly in Egypt, Hungary, and near Merida in

South America. It exists in these localities in solution in small lakes, from which it is extracted in consequence of the drying up of the water during the heats of summer. Native soda is called *natron*, and was formerly imported from Egypt for use in the arts; but for a number of years, the demands of commerce for this alkali have been supplied from other sources. The native soda of Egypt, called *trona*, by the natives, is a sesquicarbonate; while the South American is intermediate, in the proportion of its acid, between the Egyptian and artificial carbonate. None of these native sodas are important to the American chemist or druggist, as they are never imported into this country.

Soda of vegetable origin is derived from certain plants which grow on the surface or borders of the sea, and is denominated either *barilla* or *kelp*, according to the particular character of the marine plants from which it is derived. *Barilla* is obtained from several vegetables, principally belonging to the genera *Salsola*, *Salicornia*, and *Chenopodium*. In Spain, Sicily, and some other countries, the plants are regularly cultivated for the purpose of yielding soda by their combustion. The plants, when ripe, are cut down, dried, and burnt in heaps. The ashes form a semi-fused, hard, and compact saline mass, which is broken up into fragments by means of pickaxes, and thrown into commerce. *Kelp* is procured by the incineration of various kinds of sea-weeds, principally the algæ and fuci, which grow on the rocky coasts of many countries. The Orkneys and Hebrides, and the rocky coasts of Wales, Scotland, and Ireland, furnish large quantities of these weeds. The plants are allowed to ferment in heaps, then dried, and afterwards burnt to ashes in ovens, roughly made with brick or stone, and built in the ground. The alkali in the ashes melts, and forms the whole into one solid mass. When cold, it is broken up with iron instruments into large heavy masses, in which state it is found in commerce. About twenty-four tons of sea weeds are required to produce one of kelp. Large quantities of this substance were formerly manufactured in Great Britain; but its demand and production have almost ceased since the introduction of artificial soda at a comparatively low price. An impure soda is obtained in a similar manner in France, under the name of *vareck*.

Artificial Soda of Commerce. At present this is obtained by decomposing sulphate of soda, which is procured from the manufacturers of chlorinated lime (bleaching salt), or, what is more usual, on account of the insufficient supply from this source, is made expressly for the purpose, by decomposing common salt (chloride of sodium) by sulphuric acid. The dried sulphate is mixed with its own weight of ground chalk, and half its weight of small coal, ground and sifted, and the whole is heated in a reverberatory furnace, where it fuses and forms a black mass, called *black ash* or *British barilla*. The coal, at the temperature employed, converts the sulphate of soda into sulphuret of sodium. This reacts with the chalk, so as to form sulphuret of calcium and carbonate of soda, ($\text{NaS} + \text{CaO}, \text{CO}_2 = \text{CaS} + \text{NaO}, \text{CO}_2$). Black ash contains only about 22 per cent. of alkali, imperfectly carbonated on account of the high heat used, the remainder being sulphuret of calcium and coaly matter. It is next digested in warm water, which takes up the alkali and leaves the impurities. The solution is evaporated to dryness, and the mass obtained calcined with one-fourth of its weight of sawdust, in order to convert the alkali fully into carbonate, by means of the carbonic acid resulting from the combustion of the sawdust. The product is redissolved in water, and the solution evaporated to dryness. The alkali, in this stage of its purification, contains about 50 per cent. of carbonate of soda, and is called *soda-ash*. It is brought to the state of crys-

tallized carbonate of soda by dissolving it in water, straining the solution, evaporating it to a pellicle, and setting it aside to crystallize.

The chemical process just described for obtaining carbonated soda, is at present pursued on an immense scale in Great Britain, especially at Liverpool and Glasgow; and its product is so cheap that its use has nearly superseded that of barilla and kelp for manufacturing purposes. It was calculated by Mr. Musprat that, in 1838, there were manufactured in Great Britain alone, 50,000 tons of soda-ash, and 20,000 tons of the crystallized carbonate, and the manufacture is steadily on the increase.

Barilla, when of good quality, is in hard, dry, porous, sonorous, grayish-blue masses, which become covered with a saline efflorescence after exposure to the air. It possesses an alkaline taste and peculiar odour. It contains from twenty-five to forty per cent. of real carbonated alkali, the residue being made up of sulphate of soda, sulphuret and chloride of sodium, carbonate of lime, alumina, silica, oxide of iron, and a small portion of charcoal which has escaped combustion.

Kelp is in hard, vesicular masses, of a dark-gray, bluish, or greenish colour, sulphureous odour, and acrid, caustic taste. It is still less pure than barilla, containing from five to eight per cent. of carbonated soda; the rest being made up of a large proportion of the sulphates of soda and potassa, and the chlorides of potassium and sodium, a small quantity of iodide of sodium, and insoluble and colouring matters. It is from kelp that iodine is obtained. (See *Iodinum*.)

British barilla, the name given to artificial soda in its lowest degree of purity, is of a blackish-brown colour, becoming darker by exposure to the air. When broken it exhibits an imperfect metallic lustre, and a close striated texture. Its taste is caustic and hepatic. By exposure to a moist atmosphere, it becomes covered with a yellow efflorescence, and quickly falls to powder, with disengagement of heat and sulphuretted hydrogen; at the same time increasing in weight by the absorption of carbonic acid and water. *Soda-ash* is in white or gray compact masses.

The different kinds of impure carbonate of soda, whether barilla, kelp, or soda-ash, being exceedingly variable in composition, it is important to have a ready method of determining the quantity of real carbonated alkali which they contain. The mode in which this is done, by means of an instrument called an alkalimeter, has been already explained. (See page 565.)

Pharmaceutical Uses, &c. The impure carbonate of soda, in the form of commercial carbonate, is employed by the London College for obtaining the pure carbonate; and barilla is used for the same purpose by the Dublin College. The various forms of impure carbonate are largely consumed in soap and glass making, and in dyeing and bleaching.

SODÆ CARBONAS. *U.S., Lond., Ed., Dub.*

Carbonate of Soda.

Carbonate de soude, *Fr.*; Einfach Kohlensaures Natron, *Germ.*; Carbonato di soda, *Ital.*; Carbonato de soda, *Span.*

In the U. S. Pharmacopœia this salt has been always placed in the list of the *Materia Medica*; the crystallized carbonate of soda, obtained on a large scale by the manufacturing chemist, being a pure salt, and that which is sold in the shops of our apothecaries. The Edinburgh College, in the late

revision of its Pharmacopœia, has given the same position to this salt, having abandoned the process previously prescribed for preparing it from barilla. The London and Dublin Colleges give processes for its preparation.

The *London* College takes *two pounds* of the "impure carbonate of soda" (commercial carbonate), boils it with *four pints* (Imperial measure) of distilled water, strains the solution while hot, and sets it by that crystals may form. The *Dublin* College exhausts "barilla," by boiling it with twice its weight of water for two or three successive times, and, having mixed the several solutions, evaporates to dryness. The dry mass is then dissolved in boiling water, and the solution evaporated until it acquires the sp. gr. 1.22, when it is exposed to a temperature about freezing, in order that it may crystallize. The crystals are then dried and kept in close bottles.

These processes for obtaining carbonate of soda on a small scale are entirely superfluous, on account of the perfection to which the artificial carbonate has been brought by the manufacturing chemist. The official carbonate of soda of the U. S. and Edinburgh Pharmacopœias may be considered as this carbonate in the highest state of purity, in which it is manufactured on the large scale. The process by which it is made is described in the preceding article. (See *Sodæ Carbonas Impura*.)

Properties. Carbonate of soda is a colourless salt, possessing an alkaline and disagreeable taste, and crystallizing usually in large oblique rhombic prisms, which speedily effloresce and fall into powder when exposed to the air. It is soluble in twice its weight of cold water, but insoluble in alcohol, and displays an alkaline reaction with tests. When heated it undergoes the aqueous fusion; and, if the heat be continued, it dries and finally suffers the igneous fusion. The most usual impurities are sulphate of soda and common salt, which may be detected by converting the salt into a nitrate, and testing separate portions of this severally with the chloride of barium and nitrate of silver. Common salt is seldom entirely absent, but good specimens are free from sulphate of soda. According to the late Dr. W. R. Fisher, it is liable to contain, when badly prepared, a portion of sulphuret of sodium, which may be detected by the production of the smell of sulphuretted hydrogen upon dissolving the salt in water. (*Amer. Journ. of Pharm.* viii. 108.) Carbonate of soda is incompatible with acids, acidulous salts, lime-water, muriate of ammonia, and earthy and metallic salts. It consists of one eq. of carbonic acid 22.12, and one of soda 31.3 = 53.42. When fully crystallized it contains ten eqs. of water 90, giving as the number representing the crystallized salt 143.42. It is thus perceived that this salt, when perfectly crystallized, contains nearly two-thirds of its weight of water; but the quantity actually present in it, as found in the shops, is variable, being dependent on the extent to which it may have undergone efflorescence.

Medical Properties and Uses. Carbonate of soda is antacid, antilithic, and resolvent. It is given principally in diseases attended with acidity of the stomach; such as gout, uric acid gravel, and certain forms of dyspepsia. It is more frequently exhibited than carbonate of potassa, as it is more easily taken, its taste being less acrid. It has also been recommended in hooping-cough, scrofula, and bronchocele. In the latter disease, Dr. Peschier of Geneva considers it more efficacious than iodine. It is given in doses of from ten grains to half a drachm, either in powder, or in solution in some bitter infusion. In consequence of the variable state in which it exists in the shops, as to the amount of water of crystallization which it contains, the dose cannot be indicated with precision. It is on this account that the salt is most conveniently administered in the dried state. (See *Sodæ Carbonas Exsiccatus*.) When taken in an overdose it acts as a corrosive

and irritant poison. The best antidotes are fixed oils, acetic acid, and lemon juice. This salt is used, solely as a chemical agent, in preparing Quiniæ Sulphas, *Ed.*, and Antimonii Oxidum, *Ed.*

Sulphate of Soda.

Vitriolated soda, Glauber's salt; Sulfate de soude, *Fr.*; Schwefelsaures Natron, *Glaubersalz, Germ.*; Solfato di soda, *Ital.*; Sulfato de soda, Sal de Glaubero, *Span.*

This salt is included among the Preparations by the three British Colleges, a formula for obtaining it being given; but in the United States Pharmacopœia, it is inserted only in the Materia Medica list, where it properly stands as a substance obtained on a large scale.

Sulphate of soda, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad; its ingredients are present in sea-water; and it is found combined with sulphate of lime, constituting a distinct mineral. As an artificial product, it is formed in the processes for obtaining muriatic acid and chlorine, and in the preparation of muriate of ammonia, from sulphate of ammonia and common salt. It may also be procured from sea-water.

Preparation. The British Colleges agree in obtaining sulphate of soda from the salt left after the distillation of muriatic acid. This residuary salt, as is explained under muriatic acid, is sulphate of soda; but it generally contains an excess of sulphuric acid, which must be neutralized with soda or removed. The *London* College dissolves *two pounds* of the salt in *two pints* (Imperial measure) of boiling water, and saturates the excess of acid with carbonate of soda. The solution is then evaporated to a pellicle, strained, and set aside to crystallize. The supernatant liquor being poured off, the crystals are dried. The *Edinburgh* College dissolves *two pounds* of the salt in *three pints* (Imp. meas.) of boiling water, saturates the excess of acid with powdered white marble, boils the liquid and when neutral filters it, washes the insoluble matter with boiling water, which is added to the original liquid, concentrates the solution to a pellicle, and sets it aside to cool and crystallize. In the *Dublin* Pharmacopœia, the salt is directed to be dissolved in a sufficient quantity of boiling water, and the solution, after filtration and due evaporation, is allowed to crystallize by slow cooling.

In the above processes, the *London* College converts the excess of acid in the salt into an additional portion of sulphate of soda; while the *Edinburgh* College gets rid of the excess, by converting it into the insoluble sulphate of lime. The *Dublin* process makes no provision for removing the excess of acid.

Immense quantities of sulphate of soda are now obtained in Great Britain and France by the process of decomposing common salt by sulphuric acid, for the purpose of being manufactured into soda-ash and carbonate of soda; and, so far from the generated muriatic acid being a product of value, its

absorption in a convenient way, so as to avoid the nuisance of its escape into the atmosphere in a gaseous state, is the sole aim of the manufacturer. (See *Acidum Muriaticum*.)

The residuum of the process for obtaining chlorine by the action of sulphuric acid, water, and deutoxide of manganese on common salt, is a mixture of sulphate of soda and sulphate of protoxide of manganese. (See *Aqua Chlorinii*.) Large quantities of this residuum are formed in manufacturing chlorinated lime (bleaching salt), and the sulphate of soda in it, roughly purified, supplies a small part of the consumption of this salt in making soda-ash and carbonate of soda. (See *Sodæ Carbonas Impura*.)

In the process for obtaining muriate of ammonia from sulphate of ammonia and common salt, water is decomposed, and a double decomposition takes place, resulting in the formation of sulphate of soda and muriate of ammonia. By exposing the mixed salts to heat, the muriate of ammonia sublimes, and the sulphate of soda is left behind. (See *Ammonia Murias*.)

In some of our Northern States, particularly Massachusetts, a portion of Glauber's salt is procured from sea-water in the winter season. The circumstances under which it is formed, have been explained in a paper "On the Preparation of Glauber's and Epsom Salt and Magnesia from Sea-water," by Mr. Daniel B. Smith, published in the fourth volume of the Journal of the Philadelphia College of Pharmacy. The constituents of a number of salts exist in sea-water; and the binary order in which these constituents will precipitate during evaporation, depends on the temperature. During the prevalence of rigorous cold, sulphate of soda is the least soluble salt which can be formed out of the acids and bases present, and consequently it separates in the form of crystals.

Properties. Sulphate of soda is a colourless salt, possessing a cooling, nauseous, very bitter taste, and crystallizing with great facility in six-sided striated prisms. When recently prepared, it is beautifully transparent; but by exposure to the air it effloresces, and the crystals become covered with an opaque white powder. By long exposure it undergoes complete efflorescence, and falls to powder with loss of more than half its weight. It is soluble in three times its weight of cold water, and in its own weight of boiling water, but is insoluble in alcohol. Subjected to heat, it dissolves in its water of crystallization, then dries, and afterwards, by the application of a red heat, melts, with the loss of $55\frac{1}{2}$ per cent. of its weight. Occasionally it contains an excess of acid or alkali, which may be discovered by litmus or turmeric paper. The presence of common salt may be detected by sulphate of silver; that of iron by ferrocyanuret of potassium or tincture of galls. This salt is not subject to adulteration. It is incompatible with carbonate of potassa, chloride of calcium, the salts of baryta, nitrate of silver if the solutions be strong, and acetate and subacetate of lead. It consists of one eq. of sulphuric acid 40.1, one of soda 31.3, and ten of water 90=161.4.

Medical Properties and Uses. Sulphate of soda, in doses of from half an ounce to an ounce, is an efficient cathartic; in smaller doses, largely diluted, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half. It is much less used than formerly, having been almost entirely superseded by sulphate of magnesia, which is less disagreeable to the palate. Its nauseous taste, however, may be readily disguised by the admixture of a little lemon-juice or cream of tartar, or the addition of a few drops of sulphuric acid. Sulphate of soda is the principal ingredient in the artificial *Cheltenham salts*. These consist of 120 grs. of sulphate of soda, 66 grs. of sulphate of magnesia, 10 grs. of chloride of sodium, and half a

grain of sulphate of iron, and constitute, according to Dr. Paris, a very efficacious purgative. The only use of sulphate of soda in the arts is to make carbonate of soda, and as an ingredient in some kinds of glass. It has no officinal preparations.

B.

SODII CHLORIDUM. U.S., Lond.

Chloride of Sodium.

Off. Syn. SODÆ MURIAS. *Ed., Dub.*

Muriate of soda, Sea salt, Common salt; Chlorure de sodium, Hydro-chlorate de soude, Sel marin, *Fr.*; Chlornatrium, Kochsalz, *Germ.*; Salt, *Dan., Swed.*; Cloruro di sodio, Sal comune, *Ital.*; Sal, *Span.*

This mineral production, so necessary to mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it; and from its frequent presence in the solids and fluids of the animal economy, it may be supposed to perform an important part in nutrition and assimilation.

Natural State. Common salt exists in nature, either in the solid state or in solution. In the solid state, called *rock salt*, *fossil salt*, or *sal gemmæ*, it is often found forming extensive beds, and even entire mountains, from which it is extracted in blocks or masses by mining operations. Its geological position is very constant, occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it occurs in certain springs and lakes, and in the waters of the ocean. The principal salt-mines in the world are found in Poland, Hungary, and Russia; in various parts of Germany, particularly the Tyrol; in England in the county of Cheshire; in Spain; in various parts of Asia and Africa; and in Peru, and other countries of South America. In the United States there are no salt-mines, but numerous saline springs, which either flow naturally, or are produced artificially by sinking shafts to various depths, in places where salt is known to exist. These are found principally in Missouri, Kentucky, Illinois, Ohio, Pennsylvania, Virginia, and New York. In the last mentioned State the springs are the most productive; the chief ones being situated at Salina, Montezuma, and Galen. In Virginia, an important salt region exists, extending fifteen miles on each side of the great Kanawha river. Rock salt is always transparent or translucent; but it often exhibits various colours, such as red, yellow, brown, violet, blue, &c., which are supposed to be derived from iron and manganese.

Extraction. Mines of salt are worked in two ways. When the salt is pure, it is merely dug out in blocks and thrown into commerce. When impure it is dissolved in water, and extracted afterwards from the solution by evaporation. When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine, and the temperature of the place where it is found. When the water contains from fourteen to fifteen per cent. of salt, it is extracted by evaporation in large iron boilers. If, however, it contains only two, three, four, or five per cent., the salt is obtained in a different manner. If the climate be warm it is procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of spontaneous evaporation to be mentioned presently, and the subsequent application of artificial heat.

Sea water is a weak saline solution, containing 2·7 per cent. of salt, which is extracted by the agency of solar heat in warm countries. Salt thus obtained, is called *bay salt*. The extraction is conducted in Europe princi-

pally on the shores of the Mediterranean, the waters of which are salter than those of the open ocean. The mode in which it is performed is by letting in the sea-water into shallow dikes, lined with clay, and capable, after being filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. In temperate climates, weak brines are first concentrated in buildings, called *graduation houses*. These are rough wooden structures, open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of brushwood somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the faggots, upon which it is allowed to fall; and in its descent it becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and being repeated several times, the solution is at last brought to the requisite degree of strength, to permit of its final concentration in iron boilers by artificial heat. Sometimes, to save fuel, the last concentration is performed by allowing the brine to trickle down a number of vertical ropes, on the surface of which the salt is deposited in the form of a crust.

Properties. Chloride of sodium is white, without odour, and of a peculiar taste, called saline. It is usually crystallized in cubes; but by hasty evaporation it often assumes the form of hollow quadrangular pyramids. When pure it undergoes no change in the air, but when contaminated with chloride of magnesium, as not unfrequently happens, it is deliquescent. It dissolves in somewhat less than three times its weight of cold water, and is scarcely more soluble in boiling water. In weak alcohol it is very soluble, but sparingly so in absolute alcohol. Exposed to a gradually increasing heat, it first decrepitates from the presence of interstitial moisture, next melts, and finally volatilizes in white fumes without decomposition. It is decomposed by several of the acids, particularly the sulphuric and nitric, which disengage vapours of muriatic acid; by carbonate of potassa with the assistance of heat; and by the nitrates of silver and the protoxide of mercury.

Several varieties of common salt are distinguished in commerce; as *stoved salt*, *fishery salt*, *bay salt*, &c.; but they are characterized by modifications in the size and compactness of the grains, rather than by any essential difference in composition.

Composition. Common salt, in its pure state, consists of one eq. of chlorine 35.42, and one of sodium 23.3=58.72. It contains no water of crystallization. When in solution it is by some supposed to become the muriate of soda in consequence of the decomposition of water, the hydrogen and oxygen of which severally convert the chlorine and sodium into muriatic acid and soda. The common salt of commerce, besides pure chloride of sodium, contains, generally speaking, insoluble matter, and usually more or less of the sulphates of lime and magnesia, and chlorides of calcium and magnesium. When pure it is not precipitated by carbonate of soda, chloride of barium, or ferrocyanuret of potassium. Chloride of calcium is generally present in very small amount; but the chloride of magnesium sometimes amounts to 28 parts in 1000. Sulphate of lime is usually present, constituting variously from 1 part to $23\frac{1}{2}$ in 1000; and sulphate of magnesia is sometimes present and sometimes absent. To separate the earths, a boiling solution of carbonate of soda must be added, as long as any precipitate is formed. The earths will fall as carbonates, and must be separated by filtration, and sulphate of soda and chloride of sodium will remain in solution. The sulphate of soda may then be decomposed by the cautious addition of chloride of barium which will generate chloride of sodium, and insoluble sulphate of baryta.

Medical Properties and Uses. Chloride of sodium, in small doses, acts as a stimulant tonic and anthelmintic; in larger ones as a purgative and emetic. It certainly promotes digestion, and the almost universal animal appetency for it, proves it to be a salutary stimulus in health. When taken in larger quantities than usual with food, it is useful in some forms of dyspepsia, and, by giving greater tone to the digestive organs in weakly children, may correct the disposition to generate worms. On the sudden occurrence of hæmoptysis, it is usefully resorted to as a styptic, in the dose of a teaspoonful, taken dry, and often proves successful in stopping the flow of blood. Externally applied in solution it is stimulant, and may be used either locally or generally. Locally it is sometimes employed as a fomentation in sprains and bruises; and as a general external application, it forms the salt-water bath, a valuable remedy as a tonic and excitant in depraved conditions of the system, occurring especially in children, and supposed to be dependent on the scrofulous diathesis. A pound of salt dissolved in four gallons of water, forms a solution of about the strength of sea-water, and suitable for a bath. It is frequently used as an ingredient in stimulating enemata. The dose, as a tonic, is from ten grains to a drachm; as a cathartic, though seldom used for that purpose, from two drachms to half an ounce. In doses of from half an ounce to an ounce, dissolved in four or five times its weight of water, it frequently proves a prompt and efficient emetic, invigorating rather than depressing the powers of the system. When employed as a clyster, it may be used in the amount of from one to two tablespoonfuls dissolved in a pint of water.

The uses of common salt in domestic economy as a condiment and antiseptic are well known. In agriculture it is sometimes used as a manure, and in the arts is employed to prepare muriate of ammonia, as also to form sulphate of soda, with a view to its conversion afterwards into carbonate of soda. It is used as a chemical agent in preparing the biniodide of mercury of the Edinburgh College.

SOLIDAGO. U.S. Secondary.

Golden-rod.

“The leaves of *Solidago odora*.” *U.S.*

SOLIDAGO. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Asteroidæ, *De Candolle*, Asteraceæ, *Lindley*.

Gen. Ch. Calyx imbricated, scales closed. Radical florets about five, yellow. Receptacle naked, punctate. Pappus simple pilose. *Nuttall*.

This is a very abundant genus, including, according to Eaton's enumeration, upwards of sixty species belonging to this country. Of these the *S. odora* only is officinal. The *S. Virgaurea*, which is common to the United States and Europe, was formerly directed by the Dublin College; but was omitted in the last edition of their Pharmacopœia. It is astringent, and has been supposed to possess lithontriptic virtues.

Solidago odora. Willd. *Sp. Plant.* iii. 2061; Bigelow, *Am. Med. Bot.* i. 187. The sweet-scented golden-rod has a perennial creeping root, and a

slender, erect, pubescent stem, which rises two or three feet in height. The leaves are sessile, linear lanceolate, entire, acute, rough at the margin, elsewhere smooth, and, according to Bigelow, covered with pellucid dots. The flowers are of a deep golden-yellow colour, and are arranged in a terminal, compound, paniced raceme, the branches of which spread almost horizontally, are each accompanied by a small leaf, and support the flowers on downy pedicels, which put forth from the upper side of the peduncle, and have small linear bractes at their base. The florets of the ray are ligulate, oblong, and obtuse; those of the disk funnel-shaped, with acute segments.

The plant grows in woods and fields throughout the United States, and is in flower from August to October. The leaves, which are the officinal portion, have a fragrant odour, and a warm, aromatic, agreeable taste. These properties depend on a volatile oil, which may be separated by distillation with water. It is of a pale greenish-yellow colour, and lighter than water.

Medical Properties and Uses. Golden-rod is aromatic, moderately stimulant and carminative, and, like other substances of the same class, diaphoretic when given in warm infusion. It may be used to relieve pain arising from flatulence, to allay nausea, and to cover the taste or correct the operation of unpleasant or irritating medicines. For these purposes it may be given in infusion. The volatile oil dissolved in alcohol is employed in the Eastern States. According to Pursh, the dried flowers are used as a pleasant and wholesome substitute for common tea. W.

SPIGELIA. *U. S., Lond., Ed.*

Pinkroot.

“The root of *Spigelia Marilandica*.” *U. S., Ed.* “*Spigelia Marilandica. Radix.*” *Lond.*

Off. Syn. SPIGELIA MARILANDICA. *Radix. Dub.*

Spigélie du Maryland. Fr.; Spigelie, Germ.; Spigelia, Ital.

SPIGELIA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianæ, *Juss.*; Spigeliaceæ, *Martius, Lindley.*

Gen. Ch. *Calyx* five-parted. *Corolla* funnel-shaped, border five-cleft, equal. *Capsule* didymous, two-celled, four-valved, many-seeded. *Nuttall.*

There are two species of *Spigelia* which have attracted attention as anthelmintics, the *S. anthelmintica* of South America and the West Indies, and the *S. Marilandica* of this country. The former is an annual plant, used only in the countries where it grows, the latter is much employed both in this country and in Europe.

Spigelia Marilandica. Willd. *Sp. Plant.* i. 825; Bigelow, *Am. Med. Bot.* i. 142; Barton, *Med. Bot.* ii. 75. The *Carolina pink* is an herbaceous plant with a perennial root, which sends off numerous fibrous branches. The stems, several of which rise from the same root, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a spike, which leans to one side, and supports from four to twelve flowers with very short peduncles. The calyx is persistent, with five long, subulate, slightly serrate leaves, reflexed in the ripe fruit. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine colour externally, becoming paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens,

though apparently very short, and inserted into the upper part of the tube between the segments, may be traced down its internal surface to the base. The anthers are oblong, heart-shaped; the germ superior, ovate; the style about the length of the corolla, and terminating in a linear fringed stigma projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions, and containing many seeds.

The plant is a native of our Southern and South-western States, being seldom if ever found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The root is the part recognised as officinal in the United States Pharmacopœia. The drug was formerly collected in Georgia and the neighbouring States by the Creek and Cherokee Indians, who disposed of it to the white traders. The whole plant was gathered and dried, and came to us in bales or casks. After the emigration of the Indians, the supply of spigelia from this source very much diminished, and has now nearly if not entirely failed. The consequence was for a time a great scarcity and increase in the price of the drug; but a new source of supply was opened from the Western and South-western States, and it is now again plentiful. As we receive spigelia at present, it is chiefly if not exclusively in the root, without the stem and leaves. We have been informed that most of it comes in casks or bales from St. Louis, by the way of New Orleans. That contained in casks is to be preferred, as less liable to be damp and mouldy.

Properties. Pink-root consists of numerous slender, branching, crooked, wrinkled fibres; from three to six inches long, attached to a knotty head or caudex, which exhibits traces of the stems of former years. It is of a brownish or yellowish-brown colour externally, of a faint smell, and a sweetish, slightly bitter, not very disagreeable taste. Its virtues are extracted by boiling water. The root, analyzed by M. Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassa and lime, &c., and woody fibre. The principle upon which the virtues of the root are thought to depend, is brown, of a bitter nauseous taste, like that of the purgative matter of the leguminous plants, and when taken internally produces vertigo and a kind of intoxication.

The stalks of the dried plant are oval below the first pair of leaves, and then become obscurely four-sided. The leaves, when good, have a fresh greenish colour, and an odour somewhat like that of tea. In taste they resemble the root, and afforded to M. Feneulle nearly the same principles. The quantity, however, of the bitter substance was less, corresponding with their inferior efficacy. This circumstance should cause their rejection from the shops, as the inequality in power of the two portions of the plant would lead to uncertainty in the result, when they are both employed. The root alone is wisely directed by the Pharmacopœias.

The roots are sometimes mixed with those of other plants, particularly of a small vine which twines round the stem of the *Spigelia*. These are long, slender, crooked, yellowish, thickly set with short capillary fibres, and much smaller and lighter coloured than the pink-root. They should be separated before the latter is used. The activity of spigelia is somewhat diminished by time.

Medical Properties and Uses. Pink-root is generally considered among the most powerful anthelmintics. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it excites the

circulation, and determines to the brain, giving rise to vertigo, dimness of vision, dilated pupils, spasms of the facial muscles, and sometimes even to general convulsions. Spasmodic movements of the eyelids have been observed among the most common attendants of its narcotic action. The death of two children who expired in convulsions was attributed by Dr. Chalmers to the influence of spigelia. The narcotic effects are said to be less apt to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great, as it is in very general use in the United States, both in regular and domestic practice; and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia were first learned from the Cherokee Indians. They were made known to the medical profession by Drs. Lining, Garden, and Chalmers of South Carolina. The remedy stands at present in this country at the head of the anthelmintics. It has also been recommended in infantile remittents and other febrile diseases; but is entitled to little confidence in these complaints.

It may be given in substance or infusion. The dose of the powdered root for a child three or four years old, is from ten to twenty grains, for an adult from one to two drachms, to be repeated morning and evening for several days successively, and then followed by a brisk cathartic. The practice of preceding its use by an emetic has been generally abandoned. It is frequently given in combination with calomel. The infusion, however, is the most common form of administration. (See *Infusum Spigeliæ*.) It is usually combined with senna or some other cathartic, to ensure its action on the bowels. A preparation generally kept in the shops and much prescribed by physicians, under the name of *worm tea*, consists of pink-root, senna, manna, and savine, mixed together, in various proportions, to suit the views of different individuals.

SPIRÆA. U. S. Secondary.

Hardhack.

“The root of *Spiræa tomentosa*.” U. S.

SPIRÆA. *Sex. Syst.* Icosandria Pentagynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. *Calyx* spreading, five-cleft, inferior. *Petals* five, equal, roundish. *Stamens* numerous, exserted. *Capsules* three to twelve, internally bivalve; each one to three-seeded. *Nuttall*.

Spiræa tomentosa. Willd. *Sp. Plant.* ii. 1056; Rafinesque, *Med. Flor.* vol. ii. This is an indigenous shrub, two or three feet high, with numerous simple, erect, round, downy, and purplish stems, furnished with alternate leaves closely set upon very short footstalks. The leaves are ovate lanceolate, unequally serrate, somewhat pointed at both ends, dark green on their upper surface, whitish and tomentose beneath. The flowers are of a beautiful red or purple colour, and disposed in terminal, compound, crowded spikes or racemes.

The hardhack flourishes in low grounds, from New England to Carolina, but is most abundant in the Northern States. It flowers in July and August. All parts of it are medicinal. The root, though designated in the Pharmacopœia, is, according to Dr. A. W. Ives, the least valuable portion. The taste of the plant is bitter and powerfully astringent. Among its constitu-

ents are tannin, gallic acid, and bitter extractive. Water extracts its sensible properties and medicinal virtues.

Medical Properties and Uses. Spiræa is tonic and astringent, and may be used in diarrhœa, cholera infantum, and other complaints in which astringents are indicated. In consequence of its tonic powers it is peculiarly adapted to cases of debility; and, from the same cause, should not be given during the existence of inflammatory action, or febrile excitement. It is said to have been employed by the aborigines of our country; but was first brought to the notice of the medical profession by Dr. Cogswell of Hartford, in Connecticut. It is said to be less apt to disagree with the stomach than most other astringents.

The form in which it is best administered is that of an extract, prepared by evaporating the decoction of the leaves, stems, or root. The dose is from five to fifteen grains, repeated several times a day. A decoction prepared by boiling an ounce of the plant in a pint of water, may be given in the dose of one or two fluidounces.

SPONGIA. U.S., Ed.

Sponge.

“*Spongia officinalis.*” U.S., Ed.

Off. Syn. SPONGIA OFFICINALIS. *Dub.*

Eponge, *Fr.*; Badeschwamm, *Germ.*; Spugna, *Ital.*; Esponja, *Span., Portug.*; Isfung, *Arab.*

The sponge is now generally admitted to be an animal. It is characterized as “a flexile, fixed, torpid, polymorphous animal, composed either of reticulate fibres, or masses of small spires interwoven together, and clothed with a gelatinous flesh full of small mouths on its surface, by which it absorbs and ejects water.” More than two hundred and fifty species have been described by naturalists, of which several are probably employed, though the *Spongia officinalis* is the only one designated in the Pharmacopœias. They inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies; and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, and in those of the East and West Indies. In the Grecian Archipelago many persons derive their support altogether from diving for sponges. When first collected they are enveloped in a gelatinous coating, which forms part of the animal, and is separated by washing with water. Large quantities of the coarser kinds are imported from the Bahamas; but the finest and most esteemed are brought from the Mediterranean.

Sponge, as found in commerce, is in yellowish-brown masses of various shape and size, light, porous, elastic, and composed of fine, flexible, tenacious fibres, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by muriatic acid diluted with thirty parts of water. By this process, it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming *burnt sponge*, the coarser will answer equally well.

According to Mr. Hatchett, the chemical constituents of sponge are gelatin, coagulated albumen, common salt, and carbonate of lime. The presence of magnesia, silica, iron, and phosphorus has also been detected; and iodine and bromine combined with sodium and potassium are among the ingredients.

Medical Properties and Uses. Sponge, in its unaltered state, is not employed as a medicine; but in consequence of its softness, porosity, and property of imbibing liquids, it is very useful in surgical operations. From the same qualities it may be advantageously applied over certain ulcers, the irritating sanies from which it removes by absorption. Compressed upon a bleeding vessel, it is sometimes useful for promoting the coagulation of the blood, especially in hemorrhage from the nostrils. In the shape of sponge tent it is also useful for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge expanding by the imbibition of moisture, gradually dilates the wound or ulcer in which it may be placed. Reduced to the state of charcoal by heat, sponge has long been used as a remedy in goitre. (See *Spongia Usta*.) Its efficacy in this complaint, which was formerly considered very doubtful by many physicians, has been generally admitted since the discovery of iodine.

STANNUM. U.S., Lond., Ed., Dub.

Tin.

Etain, Fr.; Zinn, Germ.; Stagno, Ital.; Estanno, Span.

Tin is one of those metals which have been known from the earliest ages. It exists in the earth generally as an oxide (*tin stone* and *wood tin*), rarely as a sulphuret (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe; in the island of Banca and the peninsula of Malacca in Asia; and in Chili and Mexico. A valuable tin ore has been lately discovered in the United States, at Jackson, New Hampshire. The Cornwall mines are the most celebrated and productive, but those of Asia furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its purest state, under the form of detached roundish grains, called *stream tin*, the reduction is effected simply by heating with charcoal. When the oxide is extracted from mines, called *mine tin*, it requires to be freed, by pounding and washing, from the adhering gangue; after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is not pure, and requires to be subjected to a gentle heat, whereby the pure tin enters first into fusion, and is thus separated from the impurities, which consist of tin united with copper, arsenic, iron, and antimony. The pure metal thus obtained, is the *grain-tin* of the English; while the impure residue, after being fused, constitutes *block-tin*.

Properties. Tin is a malleable, rather soft metal, of a silver-white colour, and possessing considerable brilliancy. It occurs in the shops, beaten out into thin leaves, called *tin foil*. It undergoes but a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar smell. Its ductility and tenacity are small, and when bent to and fro, it emits a crackling noise, which is characteristic of this metal. Its sp. gr. is 7.29, melting point 442°.

equiv. number 58·9, and symbol Sn. It forms three oxides, a protoxide, sesquioxide, and deutoxide. The *protoxide* is of a grayish-black colour, and consists of one eq. of tin 58·9, and one of oxygen 8=66·9. The *sesquioxide* is gray, and is composed of two eqs. of tin 117·8, and three of oxygen 24=141·8. The *deutoxide* is of a white colour, and constitutes the native oxide. It consists of one eq. of tin 58·9, and two of oxygen 16=74·9.

The tin of commerce is often impure, being contaminated with other metals, introduced by fraud, or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its colour has a bluish or grayish cast, the presence of copper, lead, iron, or antimony may be suspected. Arsenic renders it whiter, but at the same time harder than natural; and lead, copper, and iron cause it to become brittle. Pure tin is converted by nitric acid into a white powder (*deutoxide*), without being dissolved. Boiled with muriatic acid, it forms a solution which gives a white precipitate with ferrocyanuret of potassium. A blue precipitate with this test indicates iron; a brown one, copper; and a violet-blue one, both iron and copper. If lead be present, a precipitate will be produced by sulphate of magnesia. The Malacca and Banca tin, and the English grain-tin are the purest kinds found in commerce. Block tin and the metal obtained from Germany are always of inferior quality. The common tin of the shops has a density of about 7·56.

Uses. Tin enters into the composition of bronze, bell-metal, pewter, and plumbers' solder. It is used also in making tin-plate, in silvering looking-glasses, and in forming the solution of bichloride of tin, a combination essential to the perfection of the scarlet dye. It is employed in fabricating various vessels and instruments, useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. For its medical properties, see *Pulvis Stanni*.

STAPHISAGRIA. *Lond.*, *Ed.*

Stavesacre.

"Delphinium Staphisagria. *Semina.*" *Lond.* "Seeds of Delphinium Staphisagria." *Ed.*

Off. Syn. DELPHINIUM STAPHISAGRIA. *Semina.* *Dub.*

Staphisaigre, *Fr.*; Stephanskraut, Läusekraut, *Germ.*; Stafisagria, *Ital.*; Abarraz, *Span.*

DELPHINIUM. See DELPHINIUM.

Delphinium Staphisagria. Willd. *Sp. Plant.* ii. 1231; Woodv. *Med. Bot.* p. 471. t. 168. Stavesacre is a handsome annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five or seven-lobed leaves supported on hairy footstalks. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The nectary is four-leaved and shorter than the petals, which are five in number, the uppermost projected backward so as to form a spur which encloses two spurs of the upper leaflets of the nectary. The seeds are contained in straight, oblong capsules. The plant is a native of the South of Europe.

Properties. Stavesacre seeds are large, irregularly triangular, wrinkled, externally brown, internally whitish and oily. They have a slight but disagreeable odour, and an extremely acrid, bitter, hot, nauseous taste. Their

virtues are extracted by water and alcohol. Analyzed by MM. Lassaigne and Feneulle, they yielded a brown and a yellow bitter principle, a volatile oil, a fixed oil, albumen, an azotized substance, a mucilaginous saccharine matter, mineral salts, and a peculiar vegetable alkali called *delphine* or *delphinia*, which exists in the seeds combined with an excess of malic acid. It is white, pulverulent, inodorous, of a bitter acrid taste, fusible by heat and becoming hard and brittle upon cooling, slightly soluble in cold water, very soluble in alcohol and ether, and capable of forming salts with the acids. It is obtained by boiling a decoction of the seeds with magnesia, collecting the precipitate, and treating it with alcohol, which dissolves the *delphinia* and yields it upon evaporation. According to M. Couerbe, this substance consists of three distinct principles—one of a resinous nature separated from its solution in diluted sulphuric acid by the addition of nitric acid, another distinguished by its insolubility in ether, and named by M. Couerbe *staphisain*, and the third soluble both in alcohol and ether, and deserving to be considered as pure *delphinia*. (*Journ. de Pharm.* xix. 519.)

Medical Properties and Uses. The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of the violence of their action. Powdered and mixed with lard they are employed in some cutaneous diseases, and to destroy lice in the hair. An infusion in vinegar has been applied to the same purpose. Dr. Turnbull states that he has employed a strong tincture with advantage as an embrocation in rheumatic affections. In some countries the seeds are used to intoxicate fish in the same manner as the *Cocculus Indicus*. *Delphinia* is highly poisonous in small doses, exerting its effects chiefly on the nervous system. This, at least, was the statement made in relation to it before the appearance of Dr. Turnbull's work, *On the Medical Properties of the Ranunculacæ*. According to this author, pure *delphinia* may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting, and without producing much intestinal irritation, though it sometimes purges. In most instances it proves diuretic, and gives rise to sensations of heat and tingling in various parts of the body. Externally employed, it acts like *veratria*, and is applicable to the same complaints; but, according to Dr. Turnbull, produces more redness and burning, and less tingling than that substance. He has employed it in neuralgia, rheumatism, and paralysis, and in the last complaint considers it preferable to *veratria*. It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkali to an ounce of the vehicle; and the friction should be continued till a pungent sensation is produced.

W.

STATICE. U. S. Secondary.

Marsh Rosemary.

“The root of *Statice Caroliniana*.” U. S.

STATICE. *Sex. Syst.* Pentandria Pentagynia.—*Nat. Ord.* Plumbaginaceæ.

Gen. Ch. *Calyx* one-leaved, entire, plaited, scariose. *Petals* five. *Seed* one, superior. *Nuttall*.

Statice Caroliniana. Walter, *Flor. Car.* 118; Bigelow, *Am. Med. Bot.* ii. 51. This is considered by Nuttall, Torrey, and some other botanists, as a mere variety of the *Statice Limonium* of Europe. Pursh, Bigelow, and others follow Walter in considering it as a distinct species. It is an indi-

genous maritime plant, with a perennial root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse, mucronate, smooth, and supported on long footstalks. They differ from the leaves of the *S. Limonium* in being perfectly flat on the margin, while the latter are undulated. The flower-stem is round, smooth, from a few inches to a foot or more in height, sending off near its summit numerous alternate subdividing branches, which terminate in spikes, and form altogether a loose panicle. The flowers are small, bluish-purple, erect, upon one side only of the common peduncle, with a mucronate scaly bracte at the base of each, a five-angled, five-toothed calyx, and spatulate, obtuse petals.

The marsh rosemary grows in the salt marshes along the seacoast, from New England to Florida, and flowers in August and September. The root, which is the officinal portion, is large, spindle-shaped or branched, fleshy, compact, rough, and of a purplish-brown colour. It is bitter and extremely astringent to the taste, but is without odour. Mr. Edward Parrish, of Philadelphia, found it to contain tannic acid, gum, extractive, albumen, volatile oil, resin, caoutchouc, colouring matter, lignin, and various salts, among which were common salt and the sulphates of soda and magnesia. The proportion of tannic acid was 12.4 per cent. (*Am. Journ. of Pharm.* xiv. 116.)

Medical Properties and Uses. Statice is powerfully astringent, and in some parts of the United States, particularly in New England, is much employed. It may be used for all the purposes for which kino and catechu are given; but its chief popular application is to aphthous and ulcerative affections of the mouth and fauces. Dr. Baylies of Massachusetts found it highly useful in cynanche maligna, both as an internal and local remedy. It is employed in the form of infusion or decoction. W.

STILLINGIA. U.S. Secondary.

Queen's-root.

"The root of *Stillingia sylvatica*." U.S.

STILLINGIA. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiacæ.

Gen. Ch. MALE. *Involucre* hemispherical, many-flowered, or wanting. *Calyx* tubular, eroded. *Stamens* two and three, exserted. FEMALE. *Calyx* one-flowered, inferior. *Style* trifid. *Capsule* three-grained. *Nuttall.*

Stillingia sylvatica. Willd. *Sp. Plant.* iv. 588. This is an indigenous perennial plant, with herbaceous stems, and alternate, sessile, oblong or lanceolate oblong, obtuse, serrulate leaves, tapering at the base, and accompanied with stipules. The male and female flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The male florets are scarcely longer than the bracteal scales.

The plant grows in pine barrens, from Virginia to Florida, flowering in May and June. When wounded, it emits a milky juice. The root, which is the part used, is large, thick, and woody. We are not acquainted with its precise properties; but understand that it is much employed in the Southern States. It is said to be purgative and alterative; and probably possesses more or less of the acrid quality common to the Euphorbiacæ. It is used in lues venerea, obstinate cutaneous affections, and other complaints which are usually treated with sarsaparilla. W.

DATURA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-shaped, plaited. Calyx tubular, angular, deciduous. Capsule four-valved. *Willd.*

Datura Stramonium. Willd. *Sp. Plant.* i. 1008; Bigelow, *Am. Med. Bot.* i. 17; Woodv. *Med. Bot.* p. 197. t. 74. The thornapple is an annual plant, of rank and vigorous growth, usually about three feet high, but in a very rich soil sometimes rising six feet or more. The root is large, whitish, and furnished with numerous fibres. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves, which stand on short round footstalks in the forks of the stem, are five or six inches long, of an ovate triangular form, irregularly sinuated and toothed at the edges, unequal at the base, of a dark-green colour on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled; having a tubular, pentangular, five-toothed calyx, and a funnel-shaped corolla with a long tube, and a waved plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflexed, and remains attached to the fruit. This is a large, fleshy, roundish ovate, four-valved, four-celled capsule, thickly covered with sharp spines, and containing numerous seeds attached to a longitudinal receptacle in the centre of each cell. It opens at the summit.

Dr. Bigelow describes two varieties of this species of *Stramonium*, one with green stems and white flowers; the other with a dark reddish stem, minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter variety, however, is considered by most botanists as a distinct species, being the *D. Tatula* of Linn. The properties of both are the same.

It is doubtful to what country this plant originally belonged. Many European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South Ame-

rica or Asia; and it is probable that its native country is to be found in some portion of the East. Its seeds, being retentive of life, and easily germinating, are taken in the earth put on shipboard for ballast from one country to another, not unfrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connexion. In the United States it is found everywhere in the vicinity of cultivation, frequenting dung-heaps, the road-sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odour which it diffuses to some distance around. All parts of it possess medicinal properties. The herbaceous portion is directed by the Edinburgh College; the herb and seeds by that of Dublin; the leaves and seeds by the London College; and the leaves, root, and seeds by the Pharmacopœia of the United States. The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In the common language of this country, the plant is most known by the name of *Jamestown weed*, derived probably from its having been first observed in the neighbourhood of that old settlement in Virginia. In Great Britain it is called *thornapple*.

1. The *fresh leaves* when bruised emit a fetid narcotic odour, which they lose upon drying. Their taste is bitter and nauseous. These properties, together with their medical virtues, are imparted to water and alcohol. Water distilled from them, though possessed of their odour in a slight degree, is destitute of their active properties. They contain, according to Promnitz, 0.58 per cent. of gum, 0.6 of extractive, 0.64 of green starch, 0.15 of albumen, 0.12 of resin, 0.23 of saline matters, 5.15 of lignin, and 91.25 of water. The leaves, if carefully dried, though they lose their odour, retain their bitter taste.

2. The *seeds* are small, kidney-shaped, flattened on the sides, of a dark brown almost black colour, inodorous, and of the bitter nauseous taste of the leaves, with some degree of acrimony. They were minutely analyzed by Brandes, who found, besides a peculiar alkaline principle called *daturia*, a glutinous matter, albumen, gum, a butyraceous substance, green wax, resin insoluble in ether, fixed oil, bassorin, sugar, gummy extractive, orange-coloured extractive, and various saline and earthy substances. According to Brandes, *daturia* exists in the seeds combined with an excess of malic acid. Chemists, however, have failed in obtaining such a principle by the process given by Brandes; and Berzelius states that the *daturia* of Brandes has been ascertained, even by that chemist himself, to be nothing more than phosphate of magnesia. (*Traité de Chimie*, vi. 319.) But Geiger and Hesse succeeded in isolating an alkaline principle, to which the same name has been given, and which Trommsdorff has repeatedly procured by their process.

As described by Geiger and Hesse, *daturia* crystallizes in colourless, inodorous, shining prisms, which, when first applied to the tongue, are bitterish, but ultimately have a flavour like that of tobacco. It is dissolved by 280 parts of cold, and 72 of boiling water, is very soluble in alcohol, and less so in ether. It has been shown to have a poisonous action upon animals, and strongly dilates the pupil. It was procured from the seeds in the same manner as *hyoscyamia* from those of *Hyoscyamus Niger*. (See *Hyoscyamus*.) The product is exceedingly small. In the most favourable case, Trommsdorff got only $\frac{1}{50}$ of one per cent. (*Annal. der Pharm.* xxxii. 275.) Mr. Morries obtained a poisonous empyreumatic oil by the destructive distillation of stramonium.

Medical Properties and Uses. Stramonium is a powerful narcotic. When taken in quantities sufficient to affect the system moderately, it usually produces more or less cerebral disturbance, indicated by vertigo, headache, dimness or perversion of vision, and confusion of thought, sometimes amounting to slight delirium or a species of intoxication. At the same time peculiar deranged sensations are experienced about the fauces, œsophagus, and trachea, increased occasionally to a feeling of suffocation, and often attended with nausea. A disposition to sleep is sometimes, but not uniformly produced. The pulse is not materially affected. The bowels are rather relaxed than confined, and the secretions from the skin and kidneys not unfrequently augmented. These effects pass off in five or six hours, or in a shorter period, and no inconvenience is subsequently experienced. (*Marcet, Greding, &c.*) Taken in poisonous doses, this narcotic produces cardialgia, excessive thirst, nausea and vomiting, a sense of strangulation, anxiety and faintness, partial or complete blindness with dilatation of the pupil, vertigo, delirium sometimes of a furious sometimes of a whimsical character, tremors of the limbs, palsy, and ultimately stupor and convulsions. From all these symptoms the patient may recover; but in numerous instances they have terminated in death. To evacuate the stomach by emetics or the stomach pump is the most effectual means of affording relief.

Though long known as a poisonous and intoxicating herb, stramonium was first introduced into regular practice by Baron Störck of Vienna, who found some advantage from its use in mania and epilepsy. Subsequent observation has confirmed his estimate of the remedy; and numerous cases are on record in which benefit has accrued from it in these complaints. It can be of use, however, only in those cases which depend solely on irregular nervous action. Other diseases in which it has been found beneficial are neuralgic and rheumatic affections, dysmenorrhœa, syphilitic pains, cancerous sores, and spasmodic asthma. In the last complaint it has acquired considerable reputation. It is employed only during the paroxysm, which it very often greatly alleviates or altogether subverts. The practice was introduced into Great Britain from the East Indies, where the natives are in the habit of smoking the dried root and lower part of the stem of the *Datura ferox*, in the paroxysms of this distressing complaint. The same parts of the *D. Stramonium* were substituted and found equally effectual. To prepare the roots for use, they are quickly dried, cut into pieces, and beat so as to loosen the texture. The dried leaves answer the same purpose. They are smoked by means of a common tobacco-pipe. These and other narcotic leaves have also been used in the shape of cigars. The smoke produces a sense of heat in the lungs, followed by copious expectoration, and attended frequently with temporary vertigo or drowsiness, and sometimes with nausea. The remedy should never be used in plethoric cases, unless preceded by ample depletion, and in no case where there is a determination to the head. Dangerous and even fatal consequences are said to have resulted from its incautious or improper use; and General Gent, who was instrumental in introducing the practice into England, is said at last to have fallen a victim to it. (*Pereira's Mat. Med.*) Stramonium has sometimes been given by the stomach in the same complaint. It is used by Dr. H. D. W. Pawling in the treatment of delirium tremens, and, as represented in the inaugural dissertation of his pupil Dr. G. W. Holstein, with great success. Dr. Pawling employs a decoction of the leaves.

Externally the medicine is used advantageously as an ointment or cataplasm in irritable ulcers, inflamed tumours, swelling of the mammæ, and painful hemorrhoidal affections. By American surgeons it is very frequently applied to the eye, in order to produce dilatation of the pupil, previously to

the operation for cataract; and is found equally efficacious with belladonna. For this purpose the extract, mixed with lard, is generally rubbed over the eyelid, or a solution of it dropped into the eye.

Of the parts of the plant employed, the seeds are the most powerful. They may be given in the dose of a grain twice a day; and an extract made by evaporating the decoction, in one quarter or half of the quantity. The dose of the powdered leaves is two or three grains. The inspissated juice of the fresh leaves, which is the official extract, is more commonly prescribed than any other preparation, and may be administered in the quantity of one grain. (See *Extractum Stramonii.*) There is also an official tincture to which the reader is referred. Whatever preparation is used, the dose should be gradually increased till the narcotic operation becomes evident, or relief from the symptoms of the disease is obtained. The quantity of fifteen or twenty grains of the powdered leaves, and a proportionate amount of the other preparations, have often been given daily without unpleasant effects.

Storax, Fr., Germ; Storace, Ital; Estoraque, Span.

STYRAX. See BENZOINUM.

Styrax officinale. Willd. *Sp. Plant.* ii. 623; Woodv. *Med. Bot.* p. 291. t. 101. This species of *Styrax* is a tree which rises from fifteen to twenty-five feet in height, sends off many branches, and is covered with a rough gray bark. The leaves are alternate, petiolate, entire, oval, pointed, bright-green on their upper surface, white with a cotton-like down upon the under, about two inches in length, and an inch and a half in breadth. The flowers are united in clusters of three or four at the extremities of the branches. They are white, and bear considerable resemblance to those of the orange.

This tree is a native of Syria and other parts of the Levant, and has become naturalized in Italy, Spain, and the South of France, where, however, it does not yield balsam. This circumstance has induced some naturalists to doubt whether the *Styrax officinale* is the real source of storax; and, as the *Liquidambar styraciflua* of this country affords a balsam closely analogous to that under consideration, Bernard de Jussieu conjectured that the latter might be derived from another species of the same genus, the *L. orientale* of Lamarck, which is more abundant in Syria than *Styrax*.

Storax is obtained in Asiatic Turkey by making incisions into the trunk of the tree. Several kinds are mentioned in the books. The purest is the storax in grains, which is in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety, formerly called storax calamita, from the circumstance, as is supposed, that it was brought wrapped in the leaves of a kind of reed, consists of dry and brittle masses, formed of yellowish

agglutinated tears, in the interstices of which is a brown or reddish matter. The French writers call it *storax amygdaloïde*. Both this and the preceding variety have a very pleasant odour like that of vanilla. Neither of them, however, is brought to our markets.

A third variety, which is sometimes sold as the *storax calamita*, is in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. Upon exposure, it becomes covered upon the surface with a white efflorescence of benzoic acid. It evidently consists of saw-dust, united either with a portion of the balsam, or with other analogous substances. As found in the shops of this country, it is usually in the state of a coarse, soft, dark-coloured powder, mingled with occasional light friable lumps of various magnitude, and containing very little of the balsam. When good, it should yield, upon pressure between hot plates, a brown, resinous fluid, having the odour of storax.

Another variety, found in our market, is a semi-fluid adhesive matter, called *liquid storax*, which is brown or almost black upon the surface exposed to the air, but of a slightly greenish gray colour within, and of an odour somewhat like that of the Peruvian balsam, though less agreeable. It is kept in jars, and is the most employed. What is the source of liquid storax is not certainly known. Some suppose it to be derived by decoction from the young branches of the *Liquidambar styraciflua*; but some of the genuine juice of this plant, brought from New Orleans, which we have had an opportunity of inspecting, has an odour entirely distinct from that of the substance under consideration. According to Landerer, who resides in Greece, liquid storax is obtained in the islands of Cos and Rhodes, from the bark and young twigs of the *Styrax officinale*, by subjecting them to pressure. The plant, according to the same authority, grows also on the mainland of Greece, but in that situation does not yield balsam.

General Properties. Storax has a fragrant odour and aromatic taste. It melts with a moderate heat, and when the temperature is raised takes fire and burns with a white flame, leaving a light spongy carbonaceous residue. It imparts its odour to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Newmann obtained from 480 grains of storax 120 of watery extract; and from an equal quantity 360 grains of alcoholic extract. Containing volatile oil and resin, and yielding benzoic acid by distillation, it is entitled to be ranked as a balsam. Besides these ingredients, Reinsch found in storax calamita, gum, extractive, lignin, a matter extracted by potassa, water, and traces of ammonia. Simon found, in liquid storax, cinnamic acid and a resinous substance which he considered identical with the *styracine* of Bonastre.

Medical Properties and Uses. This balsam is a stimulant expectorant, and was formerly recommended in phthisis, chronic catarrh, asthma, and amenorrhœa; but it is very seldom used at present, except as a constituent of the compound tincture of benzoin. Liquid storax has been recommended in gonorrhœa and leucorrhœa as equally effectual with copaiba, and less disagreeable. From ten to twenty grains may be given twice a day, and the dose gradually increased.

SUCCINUM. *U.S., Lond., Dub.**Amber.*

Succin, Ambre jaune, Karabé, *Fr.*; Bernstein, *Germ.*; Ambra gialla, Succino, *Ital.*; Succino, *Span.*

Amber is a kind of fossil resin, derived, probably, from extinct coniferæ, occurring generally in small detached masses, in alluvial deposits, in different parts of the world. It is found chiefly in Prussia, either on the seashore, where it is thrown up by the Baltic, or underneath the surface, in the alluvial formations along the coast. It occurs, also, in considerable quantities near Catania, in Sicily. It is most frequently associated with lignite, and sometimes encloses insects and parts of vegetables. In the United States, it was found in Maryland, at Cape Sable, near Magothy river, by Dr. Troost. In this locality it is associated with iron pyrites and lignite. It has also been discovered in New Jersey. The amber consumed in this country, however, is brought from the ports of the Baltic.

Properties. Amber is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. It becomes negatively electric by friction. Its colour is generally yellow, either light or deep; but occasionally it is reddish-brown, or even deep brown. It has no taste, and is inodorous unless when heated, when it exhales a peculiar, aromatic, not unpleasant smell. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is about 1.07. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts at 548°, swells, and at last inflames, leaving, after combustion, a small portion of ashes. Subjected to distillation in a retort furnished with a tubulated receiver, it yields, first, a sour yellow liquid; and afterwards a thin yellowish oil, with a yellow crystalline sublimate, which is deposited in the neck of the retort and the upper part of the receiver. In the mean time a considerable quantity of combustible gas is given off, which must be allowed to escape from the tubulure of the receiver. By continuing the heat the oil gradually deepens in colour, until, towards the end of the distillation, it becomes black and of the consistence of pitch. The oil obtained is called *oil of amber*; the crystalline sublimate is of an acid nature, and is denominated *succinic acid*. As thus obtained it is impure, being contaminated with the oil.

Resinous substances, particularly copal, are sometimes fraudulently mixed with amber. They may be detected by the difference in their colour and fracture, and by their not emitting the peculiar odour of amber when thrown upon hot iron.

Composition. According to Berzelius, amber consists of 1. a volatile oil of an agreeable odour in small quantity; 2. a yellow resin, intimately united with a volatile oil, very soluble in alcohol, ether, and the alkalies, easily fusible, and resembling ordinary resins; 3. another resin, also combined with volatile oil, soluble in ether and the alkalies, sparingly soluble in cold, but more soluble in boiling alcohol; 4. succinic acid; 5. a bituminous principle, insoluble in alcohol, ether, and the alkalies, having some analogy to the lac resin of John, and constituting more than four-fifths of the amber. It also contains a strongly odorous, bright yellow substance, which hardens by time, but preserves in part its odour. The ultimate constituents of amber are hydrogen 7.31, carbon 80.59, oxygen 6.73, ashes (silica, lime, and alumina,) 3.27=97.90. (*Drassier*, quoted in *Pereira's Elem. of Mat. Med.*)

Pharmaceutical Uses, &c. Amber was held in high estimation by the ancients as a medicine; but at present is employed only in pharmacy and the arts. In pharmacy it is used to prepare succinic acid and oil of amber. (See *Acidum Succinicum* and *Oleum Succini*.) In the arts, it is made into ornaments, and employed in preparing varnishes. When put to the latter use it requires to be first subjected to roasting, whereby it is rendered soluble in a mixture of linseed oil and oil of turpentine. This solution forms *amber varnish*.

Washed Sulphur.

“Sublimed sulphur, thoroughly washed with water.” *U. S.*
Off. Syn. SULPHUR SUBLIMATUM. *Ed.*

Brimstone; Soufre, *Fr.*; Schwefel, *Germ.*; Zolfo, *Ital.*; Azufre, *Span.*

The officinal forms of sulphur are the *sublimed*, the *washed*, and the *precipitated*. The sublimed sulphur is designated in the United States and London Pharmacopœias by the single word *Sulphur*; the washed sulphur, in the United States and Dublin nomenclature, as *Sulphur Lotum*. The London College has dismissed washed sulphur as an officinal preparation, and the Edinburgh College, adopting a faulty and confused nomenclature, recognises only the washed sulphur, calling it “Sulphur Sublimatum,” under the Preparations, and “Sulphur” in the *Materia Medica* list. Sublimed and washed sulphur will be noticed in this place; the precipitated sulphur, in Part II, under the “Preparations.”

Natural States. Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and vegetable matter. Among vegetables, it is particularly abundant in the cruciform plants, as, for example, in mustard. It occurs in the earth, either native or in combination. When native it is found in masses, translucent or opaque, or in the powdery form, mixed with various earthy impurities. In combination, it is usually united with certain metals, such as iron, lead, mercury, antimony, copper, and zinc, forming compounds called sulphurets. Native sulphur is most abundant in volcanic countries, and is hence called *volcanic sulphur*. The most celebrated mines of it are found at Solfaterra in the kingdom of Naples, in Sicily, and in the Roman States. It occurs also, in small quantities, in different localities in the United States.

Extraction, &c. Sulphur is obtained either from sulphur earths, or from the native sulphurets of iron and copper, called iron and copper pyrites. The sulphur earths are placed in earthen pots, set in oblong furnaces of brick-work. From the upper and lateral part of each pot proceeds a tube, which communicates with the upper part of another pot, placed outside the furnace, and perforated near its bottom to allow the melted sulphur to flow out into the vessel containing water, placed beneath. Fire being applied, the sulphur rises in vapour, leaving the impurities behind, and being condensed again, flows from the perforated pot into the vessel containing the

water. Sulphur, as thus obtained, is called *crude sulphur*, and contains about one-twelfth of its weight of earthy matter. For purification, it is generally melted in a cast iron vessel. When the fusion is complete, the impurities subside, and the purer sulphur is dipped out and poured into cylindrical wooden moulds, which give it the form of solid cylinders, about an inch in diameter, called in commerce *roll sulphur* or *cane brimstone*. The dregs of this process constitute a very impure kind of sulphur, known by the name of *sulphur vivum* in the shops.

The above process purifies the sulphur but imperfectly. At the same time it causes a considerable loss; as the dregs, just alluded to, contain a large proportion of sulphur. A more eligible mode of purification consists in distilling the crude sulphur from a large cast iron still, set in brick-work over a furnace, and furnished with an iron head. The head has two lateral communications, one with a chamber of brick-work, the other with an iron receiver, immersed in water, which is constantly renewed to keep it of the proper temperature. When the tube between the still and receiver is shut, and that communicating with the chamber is open, the sulphur condenses on its walls in the form of an impalpable powder, and constitutes *sublimed sulphur* or *flowers of sulphur*. If, on the other hand, the communication with the chamber be closed and that with the receiver opened, the sulphur condenses in the latter in the liquid form, and, when cast in cylindrical wooden moulds, forms the *roll sulphur* of commerce.

The extraction of sulphur from the sulphuret of iron is performed by distilling it in stone-ware cylinders. Half the sulphur contained in the sulphuret is volatilized by the heat, and conducted, by means of an adopter, into vessels containing water, where it condenses. The residue of the mineral is employed for making sulphate of iron, or green vitriol, by exposure to air and moisture. In the Island of Anglesea, large quantities of sulphur are obtained from copper pyrites in the process for extracting that metal. The furnaces in which the ore is roasted are connected by horizontal flues with chambers, in which the volatilized sulphur is condensed. Each chamber is furnished with a door, through which the sulphur is withdrawn once in six weeks.

According to Berzelius, a very economical method of extracting sulphur from iron pyrites is practised in Sweden, which saves the expenditure of fuel. The pyrites is introduced into furnaces with long horizontal chimneys, of which the part next to the furnace is of brick-work, while the rest is formed of wood. The pyrites is kindled below, and continues to burn of itself; and the heat generated causes the stratum immediately above the part kindled to give off half its sulphur, which becomes condensed in flowers in the wooden chimney. As the fire advances, the iron and the other half of the sulphur enter into combustion, and, by the increase of heat thus generated, cause the volatilization of a fresh portion of sulphur. In this manner, the process continues until the whole of the pyrites is consumed. The sulphur thus obtained is pulverulent and very impure, and requires to be purified by distillation from iron vessels.

Crude sulphur is employed by the manufacturers of sulphuric acid, and, as it is very variable in quality, it becomes important to ascertain its exact value. This may be done by drying a given weight of it, and submitting it to combustion. The weight of the incombustible residue, added to that lost by desiccation, gives the amount of impurity.

Crude sulphur comes to this country principally from Trieste, Messina in Sicily, and the ports of Italy, being imported for the use of the sulphuric acid manufacturers. Roll sulphur and the flowers are usually brought from Marseilles.

Properties. Sulphur is an elementary non-metallic brittle solid, of a pale yellow colour, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible smell when rubbed. When pure, its sp. gr. is about 2; but occasionally, from impurity, it is as high as 2.35. Its equiv. number is 16.1, and symbol S. It is a bad conductor of heat, and becomes negatively electric by friction. It is insoluble in water, but soluble in alkaline solutions, petroleum, the fixed and volatile oils, and, provided it be in a finely divided state, in alcohol and ether. Upon being heated, it begins to volatilize at about 180° , when its peculiar odour is perceived; it melts at 225° , and at 600° , in close vessels, boils, and rises in the form of a yellow vapour, which may be condensed again, either in the liquid or pulverulent state, according as the temperature of the recipient is above or below the melting point of the sulphur. If heated in open vessels, sulphur takes fire at about the temperature of 300° , and burns with a blue flame, combining with the oxygen of the air, and giving rise to a peculiar gaseous acid, called sulphurous acid. The combinations of sulphur are numerous, and among the most powerful agents of chemistry. With oxygen it forms four acids, the *hyposulphurous*, *sulphurous*, *hyposulphuric*, and *sulphuric*, with hydrogen, *sulphohydric acid* (*hydrosulphuric acid* or *sulphuretted hydrogen*), and with the metals, various *sulphurets*. Many of its combinations are analogous to acids and bases, and are susceptible of combining with each other, forming compounds analogous to salts, and hence called by Berzelius *sulpho-salts*.

Sulphur, when obtained by roasting the native sulphurets, sometimes contains arsenic, and is thereby rendered poisonous. Volcanic sulphur is not subject to this impurity. The common English roll sulphur is sometimes made from iron pyrites, and is then apt to contain orpiment (*sesquisulphuret of arsenic*). This impurity may be detected by heating the suspected sulphur with nitric acid. The arsenic, if present, will be converted into arsenic acid; and the nitric solution, diluted with water, neutralized with carbonate of soda, and acidulated with muriatic acid, will give a yellow precipitate of persulphuret of arsenic with a stream of sulphuretted hydrogen. Sulphur, when perfectly pure, is wholly volatilized by heat, and soluble, without residue, in oil of turpentine.

The above remarks apply to sulphur generally; but in its pharmaceutical states of sublimed and washed sulphur, it presents modifications which require to be noticed.

Sublimed sulphur, usually called *flowers of sulphur* (*flores sulphuris*), is in the form of a crystalline powder of a fine yellow colour. It is always contaminated with a little sulphuric acid which is formed during its sublimation, at the expense of the oxygen of the air contained in the subliming chambers. It is on this account that this form of sulphur always reddens litmus; and if the acid be present in considerable quantity, it sometimes cakes. It may be freed from all acidity by careful ablution with hot water, when it becomes washed sulphur.

Washed sulphur is placed in the list of the *Materia Medica* in the U. S. Pharmacopœia, with an explanatory note, that it is sublimed sulphur thoroughly washed with water. The Dublin and Edinburgh Colleges include it among the Preparations. The process of the Dublin College is to pour warm water on sublimed sulphur, and to continue the washing as long as the water, when poured off, continues to be impregnated with acid, which may be known by the test of litmus. The sulphur is then dried on bibulous paper. The Edinburgh College directs the sublimation of "sulphur," and the washing of the powder obtained with boiling water, until it is freed from acid taste. The sulphur here meant is evidently not the "sulphur" of the

Materia Medica list of the Edinburgh Pharmacopœia; as this is defined to be a pure sulphur, free from acidity. Washed sulphur has the general appearance of sublimed sulphur. If properly prepared it does not affect litmus, and undergoes no change by exposure to the atmosphere.

Medical Properties and Uses. Sulphur is laxative, diaphoretic, and resolvent. It evidently passes off by the pores of the skin; as is shown by the fact that silver worn in the pockets of patients under a course of it, becomes blackened with a coating of sulphuret. The stools which it occasions are usually solid, and it is gentle in its operation, unless it contain a good deal of acid, when it causes griping; and the liability of the sublimed sulphur to contain acid, renders it less eligible for exhibition than the washed sulphur, from which all acidity is removed. The diseases in which sulphur is principally used are hemorrhoidal affections, chronic rheumatism and catarrh, atonic gout, asthma, and other affections of the respiratory organs unattended with acute inflammation. It is also much employed, both internally and externally, in cutaneous affections, especially in scabies, for the cure of which it is considered a specific. In these affections, as well as in chronic rheumatism, it is sometimes applied as an air bath, in the form of sulphurous acid gas, the head being guarded from its effects. The dose of sulphur is from one to three drachms, mixed with syrup or molasses, or taken in milk. It is often combined with bitartrate of potassa, and with magnesia.

Sulphur is consumed in the arts, principally in the manufacture of gunpowder and sulphuric acid.

TABACUM. *U. S., Lond., Ed.*

Tobacco.

“The leaves of *Nicotiana Tabacum.*” *U. S., Ed.* “*Nicotiana Tabacum. Folia exsiccata.*” *Lond.*

Off. Syn. NICOTIANA TABACUM. Folia. *Dub.*

Tabac, *Fr.*; Tabak, *Germ.*; Tobacco, *Ital.*; Tabaco, *Span.*

NICOTIANA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-shaped, with the border plaited. *Stamens* inclined. *Capsules* two-valved, two-celled. *Willd.*

Nicotiana Tabacum. Willd. *Sp. Plant.* i. 1014; Bigelow, *Am. Med. Bot.* ii. 171; Woodv. *Med. Bot.* p. 208. t. 77. The tobacco is an annual plant, with a large fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile and somewhat decurrent, very large, ovate lanceolate, pointed, entire, slightly viscid, and of a pale green colour. The lowest are often two feet long, and four inches broad. The flowers are disposed in loose terminal panicles, and are furnished with long, linear, pointed bractes at the divisions of the peduncle. The calyx is bell-shaped, hairy, somewhat viscid, and divided at its summit into five pointed segments. The

tube of the corolla is twice as long as the calyx, of a greenish hue, swelling at top into an oblong cup, and ultimately expanding into a five-lobed, plaited, rose-coloured border. The whole corolla is very viscid. The filaments incline to one side, and support oblong anthers. The pistil consists of an oval germ, a slender style longer than the stamens, and a cleft stigma. The fruit is an ovate, two-valved, two-celled capsule, containing numerous reniform seeds, and opening at the summit.

Although the original locality of this plant is not settled to the satisfaction of all botanists, there is good reason to believe that it is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. We seldom, however, see it north of Maryland. Virginia is, perhaps, the region of the world most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth, the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant, and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles, and packed in hogsheads.

Two varieties of this species are mentioned by authors, one with narrow, the other with broad leaves; but they do not differ materially in properties. Great diversity in the quality of tobacco is produced by difference of soil and mode of cultivation; and several varieties are recognised in commerce. Other species of *Nicotiana* are also cultivated, especially the *N. rustica* and *N. paniculata*, the former of which is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia rivers; and the *N. fruticosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus.

Properties. Tobacco, as it occurs in commerce, is of a yellowish-brown colour, a strong narcotic penetrating odour which is less obvious in the fresh leaves, and a bitter nauseous and acrid taste. These properties are imparted to water and alcohol. They are destroyed by long boiling; and the extract is therefore feeble or inert. An elaborate analysis of tobacco was made by Vauquelin, who discovered in it, among other ingredients, an acrid, volatile, colourless principle, slightly soluble in water, very soluble in alcohol, and supposed to be the active principle of the leaves. It was separated by a complicated process, of which, however, the most important step was the distillation of tobacco juice with potassa. In the results of this distillation Vauquelin recognised alkaline properties, which he ascribed to the presence of ammonia, but which were in part at least dependent upon the acrid principle alluded to. To this principle, which was supposed to be the active constituent of tobacco, the name of *nicotin* was given; but its alkalinity was not ascertained till a subsequent period. Another substance was obtained by Hermstadt by simply distilling water from tobacco, and allowing the liquid to stand for several days. A white crystalline matter rose to the surface, which, upon being removed, was found to have the odour of tobacco, and to resemble it in effects. It was fusible, volatilizable, similar to the nicotin of Vauquelin in solubility, and without alkaline or acid properties.

It was called *nicotianin* by Hermstadt, and appears to partake of the nature of volatile oils. Two German chemists, Posselt and Reimann, subsequently analyzed tobacco, and ascertained the alkaline nature of its active principle, which, however, neither they nor Vauquelin obtained in a state of purity. According to these chemists, 10,000 parts of the fresh leaves contain 6 parts of an alkaline principle, which they call *nicotin*, 1 of the *nicotianin* of Hermstadt, 287 of slightly bitter extractive, 174 of gum mixed with a little malate of lime, 26.7 of green resin, 26 of albumen, 104.8 of a substance analogous to gluten, 51 of malic acid, 12 of malate of ammonia, 4.8 of sulphate of potassa, 6.3 of chloride of potassium, 9.5 of potassa, which was combined in the leaves with malic and nitric acids, 16.6 of phosphate of lime, 24.2 of lime which had been combined with malic acid, 8.8 of silica, 496.9 of lignin, traces of starch, and 8828 parts of water. (*Berzelius, Traité de Chimie.*) The *nicotin* obtained by Vauquelin and by Posselt and Reimann was a colourless, volatile liquid; and, as subsequently ascertained by MM. Henry and Boutron, was in fact an aqueous solution of the alkaline principle in connexion with ammonia. It was reserved for these chemists to obtain *nicotin*, or *nicotia*, as it should now be called, in a state of purity. It exists in tobacco combined with an acid in excess, and in this state is not volatile. The following is the process employed by the last mentioned chemists. Five hundred parts of smoking tobacco were exposed to distillation in connexion with about 6000 parts of water and 200 parts of caustic soda, the heat applied being at first very moderate, and afterwards increased to the boiling point. The product of the distillation was received in a vessel containing about 30 or 40 parts of sulphuric acid, diluted with three times its weight of water; and the process was continued till nearly one-half of the liquid had come over. The product, in which care was taken to preserve a slight excess of acid, was evaporated to about 100 parts, and was then allowed to cool. A slight deposit which had formed was separated by filtration, an excess of caustic soda was added, and the liquid again distilled. A colourless very volatile acrid liquor now came over, which, being concentrated under the receiver of an air-pump, lost the ammonia which accompanied it, and assumed a syrupy consistence and more or less of the colour of amber. In this liquid, after a few days, minute crystalline plates formed; but, in consequence of their great affinity for moisture, it was difficult to isolate the crystals. This product was pure *nicotia*.

Nicotia. (*Nicotina. Nicotin.*) As usually obtained, this is a colourless or nearly colourless liquid; heavier than water; remaining liquid at 22° F.; of little smell when cold; of an exceedingly acrid burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapour, very irritant to the nostrils, with an odour recalling that of tobacco; inflammable; soluble in water, alcohol, ether, and oil of turpentine; strongly alkaline in its reaction; and capable of forming crystallizable salts with the acids. These salts are deliquescent, have a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. *Nicotia* contains a much larger proportion of nitrogen than the other organic alkalies. In its action on the animal system, it is one of the most virulent poisons known. A drop of it in the state of concentrated solution was sufficient to destroy a dog; and small birds perished at the approach of a tube containing it. Tannin forms with it a compound of but slight solubility, and might be employed as a counterpoison. It exists in tobacco in small proportion. Henry and Boutron found different varieties of tobacco to give products varying from 3.8 to 11.28 parts in 1000. It has been found in the seeds, and in very small proportion in the root. (See *Journ. de Pharm.* xxii. 689.) There can be little doubt that tobacco owes its activity to this alkali.

Nicotianin is probably the odorous principle of tobacco. Posselt and Reimann prepared it by distilling six pounds of the fresh leaves with twelve pounds of water, till one half of the liquid passed over, then adding six pounds more of water, and again distilling, and repeating this process three times. The nicotianin was obtained to the amount of eleven grains, floating on the surface of the water. It was a fatty substance, having the smell of tobacco-smoke, and an aromatic somewhat bitter taste. It was volatilizable by heat, insoluble in water, soluble in alcohol and ether, and not affected by the dilute acids, but dissolved by the solution of potassa. This was not obtained by MM. Henry and Boutron. According to Landerer, it does not exist in the fresh leaves, but is generated in the drying process. It produces sneezing when applied to the nostrils, and a grain of it swallowed by Hermstadt, occasioned giddiness and nausea.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Mr. Brodie has proved to be a most virulent poison. A single drop injected into the rectum of a cat occasioned death in about five minutes, and double the quantity administered in the same manner to a dog was followed by the same result. This oil is of a dark brown colour, of an acrid taste, and has a very peculiar smell, exactly resembling that of tobacco pipes which have been much used.

Medical Properties and Uses. Tobacco unites with the powers of a sedative narcotic, those of an emetic and diuretic; and produces these effects to a greater or less extent to whatever surface it may be applied. In addition, when snuffed up the nostrils, it excites violent sneezing and a copious secretion of mucus; when chewed, it irritates the mucous membrane of the mouth, and increases the flow of saliva; and, when injected into the rectum, it sometimes operates as a cathartic. Moderately taken, it quiets restlessness, calms mental and corporeal inquietude, and produces a state of general languor or repose, which has great charms for those habituated to the impression. In larger quantities, it gives rise to confusion of the head, vertigo, stupor, faintness, nausea, vomiting, and general debility of the nervous and circulatory functions, which, if increased, eventuates in alarming and even fatal prostration. The symptoms of its excessive action are severe retching, with the most distressing and continued nausea, great feebleness of pulse, coldness of the skin, fainting, and sometimes convulsions. It probably operates both through the medium of the nervous system, and by entering the circulation. As its local action is stimulant, we can thus account for the fact, that it excites the functions of the kidneys, at the same time that it reduces the nervous and secondarily the arterial power. The experiments of Brodie lead to the inference that the function of the heart is affected by tobacco, through the medium of the nervous system; for in a decapitated animal in which the circulation was sustained by artificial respiration, the infusion injected into the rectum did not diminish the action of the heart; while on the contrary this organ almost immediately ceased to contract when an equal dose of the poison was administered to a healthy animal. Mr. Brodie observed a remarkable difference between the operation of the infusion and that of the empyreumatic oil. After death from the former the heart was found completely quiescent, while it continued to act with regularity for a considerable time after apparent death from the latter. We may infer from this fact, either that there are two poisonous principles in tobacco, or that a new narcotic product is formed during its destructive distillation. In cases of poisoning from tobacco, the indications are, after the evacuation of the poison, to support the system by external and internal stimulants, and to allay irritation of stomach by the moderate use of opiates.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560, it was introduced into France by the ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now extensively consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature, to have thus surmounted the first repugnance to its odour and taste, and to have become the passion of so many millions. When employed in excess, it enfeebles the digestive powers, produces emaciation and general debility, and lays the foundation of serious disorders of the nervous system. Dr. Chapman informs us that he has met with several instances of mental disorder closely resembling delirium tremens, which resulted from its abuse, and which subsided in a few days after it had been abandoned.

Its remedial employment is less extensive than might be inferred from the variety of its powers. The excessive and distressing nausea which it is apt to occasion, interferes with its internal use; and it is very seldom administered by the stomach. As a narcotic it is employed chiefly to produce relaxation in spasmodic affections. For this purpose, the infusion or smoke of tobacco, or the leaf in substance in the shape of a suppository, is introduced into the rectum in cases of strangulated hernia, obstinate constipation from spasm of the bowels, and retention of urine from a spasmodic stricture of the urethra. For a similar purpose, the powdered tobacco, or common snuff, mixed with simple cerate, as recommended by the late Dr. Godman, is sometimes applied to the throat and breast in cases of croup; and Dr. Chapman has directed the smoking of a cigar in the same complaint, with decided benefit. One of the worst cases of spasm of the rima glottidis which we have seen, and which resisted powerful depletion by the lancet, yielded to the application of a tobacco cataplasm to the throat. A similar application to the abdomen is highly recommended in painters' colic. Tetanus is said to have been cured by baths made with the decoction of the fresh leaves. The relaxation produced by smoking, in a person unaccustomed to it, was very happily resorted to by Dr. Physick, in a case of obstinate and long continued dislocation of the jaw; and the same remedy has frequently been found useful in the paroxysm of spasmodic asthma. Tobacco has been highly recommended, in the form of cataplasm, in articular gout and rheumatism; and has been employed in the same way, as well as by injection, in cases of obstinate verminose affections. As an emetic, it is seldom or never employed, unless in the shape of a cataplasm to the epigastrium, to assist the action of internal medicines, in cases of great insensibility of stomach. As a diuretic it was used by Fowler in dropsy and dysury, but the practice is not often imitated. There is no better errhine than tobacco, for the ordinary purposes for which this class of medicines is employed. As a sialagogue, it is beneficial in rheumatism of the jaws, and often relieves toothache by its anodyne action. It is also used externally in the shape of cataplasm, infusion, or ointment, in cases of tinea capitis, psora, and some other cutaneous affections. The empyreumatic oil mixed with simple ointment, in the proportion of twenty drops to the ounce, has been applied with advantage, by American practitioners, to indolent tumours and ulcers; but in consequence of its liability to be absorbed, and to produce unpleasant effects on the system, it should be used with great caution. This remark is applicable to all the modes of employing tobacco; particularly to the injection of the infusion into the rectum,

which has in several instances caused the death of the patient. It is even more dangerous than a proportionate quantity introduced into the stomach; as, in the latter case, the poison is more apt to be rejected. Even the external application of the leaves or powder is not without danger, especially when the cuticle is removed. A case of death is on record occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head for the cure of tinea capitis.

Five or six grains of powdered tobacco will generally act as an emetic; but the remedy is not given in this shape. The infusion used in dropsy by Fowler, was made in the proportion of an ounce to a pint of boiling water, and given in the dose of sixty or eighty drops. The officinal infusion, which is employed for injection, is much weaker. (See *Infusum Tabaci*.) A wine and an ointment of tobacco are directed by the United States Pharmacopœia.

TAMARINDUS. *Sex. Syst.* Monadelphia Triandria.—*Nat. Ord.* Fabaceæ or Leguminosæ.

Gen. Ch. Calyx four-parted. Petals three. Nectary with two short bristles under the filaments. Legume filled with pulp. *Willd.*

Tamarindus Indica. Willd. *Sp. Plant.* iii. 577; *Woodv. Med. Bot.* p. 448. t. 161. The tamarind tree is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-coloured bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long, a sixth of an inch broad, and of a yellowish-green colour. The flowers, which are in small lateral racemes, have a yellowish calyx, and petals which are also yellow, but beautifully variegated with red veins. The fruit is a broad, compressed, reddish ash-coloured pod, very much curved, from two to six inches long, and with numerous brown, flat, quadrangular seeds, contained in cells formed by a tough membrane. Exterior to this membrane is a light-coloured acid pulpy matter, between which and the shell are several tough ligneous strings, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are very fragile, and easily separated.

The *Tamarindus Indica* appears to be a native of the East and West Indies, of Egypt, and Arabia, though believed by some authors to have been imported into America. De Candolle is doubtful whether the East and West India trees are of the same species. The pods of the former are much larger than those of the latter, and contain a greater number of seeds. At least such is the statement made by authors, who inform us that East India tamarinds contain six or seven seeds, those from the West Indies

rarely more than three or four. We have found, however, in a parcel of the latter which we have examined, numerous pods with from eight to ten seeds, and the number generally exceeded four. The fruit is the officinal portion.

Tamarinds are brought to us chiefly, if not exclusively, from the West Indies, where they are prepared by placing the pods, previously deprived of their shell, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers.

Properties. Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable sour taste, without any mixture of sweetness. As we usually find them, in the preserved state, they form a dark-coloured adhesive mass, consisting of syrup mixed with the pulp, membrane, strings, and seeds of the pod, of a sweet acidulous taste. The seeds should be hard, clean, and not swollen, the strings tough and entire, and the smell without mustiness. From the analysis of Vauquelin it appears, that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9.40 parts of citric acid, 1.55 of tartaric acid, 0.45 of malic acid, 3.25 of bitartrate of potassa, 4.70 of gum, 6.25 of jelly, 34.35 of parenchymatous matter, and 27.55 of water; so that the acidity is chiefly owing to the presence of citric acid. It is said that copper may sometimes be detected in preserved tamarinds, derived from the boilers in which they are occasionally prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a knife immersed in the tamarinds.

Medical Properties and Uses. Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful by preserving the bowels in a loose condition. It is sometimes prescribed in connexion with other mild cathartics, and is one of the ingredients of the confection of senna. Though frequently prescribed with the infusion of senna to cover the taste of that medicine, it is said to weaken its purgative power; and the same observation has been made of its influence upon the resinous cathartics in general. From a drachm to an ounce or more may be taken at a dose.

TANACETUM. U.S. Secondary.

Tansy.

“The herb of Tanacetum vulgare.” U. S.

Off. Syn. TANACETUM VULGARE. Folia. Dub.

Tanaïsie, Fr.; Gemeiner Rheinfarn, Wurmkraut, Germ.; Tanaceto, Ital., Span.

TANACETUM. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ-Senecionideæ, De Candolle; Asteraceæ, Lindley.

Gen. Ch. Receptacle naked. Pappus somewhat marginate. Calyx imbricate, hemispherical. Corolla rays obsolete, trifid. Willd.

Tanacetum vulgare. Willd. *Sp. Plant.* iii. 1814; Woodv. *Med. Bot.* p. 66. t. 27. This is a perennial herbaceous plant, rising two or three feet in height. The stems are strong, erect, obscurely hexagonal, striated, often

reddish, branched towards the summit, and furnished with alternate, doubly pinnatifid leaves, the divisions of which are notched or deeply serrate. The flowers are yellow, and in dense terminal corymbs. Each flower is composed of numerous florets, of which those constituting the disk are perfect and five-cleft, those of the ray very few, pistillate, and trifid. The calyx consists of small, imbricated, lanceolate leaflets, having a dry scaly margin. The seeds are small, oblong, with five or six ribs, and crowned by a membranous pappus.

Tansy is cultivated in our gardens, and grows wild in the roads and in old fields; but was introduced from Europe, where it is indigenous. It is in flower from July to September. The leaves are ordered by the Dublin College; but the flowers and seeds are not less effectual, and all are included in the directions of the United States Pharmacopœia.

There is a variety of the plant with curled leaves, which is said to be more grateful to the stomach than that above described, but has less of the peculiar sensible properties of the herb, and is probably less active as a medicine.

The odour of tansy is strong, peculiar, and fragrant, but much diminished by drying; the taste is warm, bitter, somewhat acrid, and aromatic. These properties are imparted to water and alcohol. According to Peschier, the leaves contain volatile oil, fixed oil, wax or stearin, chlorophylle, yellow resin, yellow colouring matter, tannin and gallic acid, bitter extractive, gum, lignin, and a peculiar acid which he calls *tanacetic*, and which precipitates lime, baryta, oxide of lead, and oxide of copper. The medical virtues of the plant depend on the bitter extractive and volatile oil. The latter, when separated by distillation, has a greenish-yellow colour, with the flavour of the plant, is lighter than water, and deposits camphor upon standing. The seeds contain the largest proportion of the bitter principle, and the least of volatile oil.

Medical Properties and Uses. Tansy has the medical properties common to the aromatic bitters. It has been recommended in intermittents, hysteria, amenorrhœa, and as a preventive of arthritic paroxysms; but at present, it is chiefly used as an anthelmintic, and in this country is scarcely employed, for any purpose, in regular practice. The seeds are said to be most effectual as a vermifuge. The dose of the powder is from thirty grains to a drachm two or three times a day; but the infusion is more frequently administered. A fatal case of poisoning with half an ounce of oil of tansy is recorded in the Medical Magazine for November, 1834. Frequent and violent clonic spasms were experienced, with much disturbance of respiration; and the action of the heart gradually became weaker till death took place from its entire suspension. No inflammation of the stomach or bowels was discovered upon dissection. (*Am. Journ. of the Med. Sci.* xvi. 256.) W.

TAPIOCA. U.S., Ed.

Tapioca.

"The fecula of the root of *Jatropha Manihot*." U. S. "Fecula of the root of *Janipha Manihot*." Ed.

JATROPHA. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. MALE. *Calyx* none, or five-leaved. *Corolla* monopetalous, funnel-shaped. *Stamens* ten, alternately shorter. FEMALE. *Calyx* none.

Corolla five-petaled, spreading. *Styles* three, bifid. *Capsule* three-celled, *Seed* one. *Willd.*

Most if not all of the species of *Jatropha* are impregnated, like other plants of the natural family of Euphorbiaceæ, with an acrid, purging, poisonous principle. The seeds of the *J. Curcas*, which are known in Europe by the name of *purging nuts*, or *Barbadoes nuts*, have properties closely similar to those of the *Croton Tiglium* and *Ricinus communis*. They are blackish, oval, about eight lines long, flat on one side, convex on the other; and the two sides present a slight longitudinal prominence. Four or five of these seeds slightly roasted, and deprived of their envelope, are sufficient to purge actively; and in a large dose they are capable of producing fatal consequences. Their active principle is said to reside exclusively in the embryo. Upon pressure they yield an oil which has all the properties of the croton oil. We are not aware that they are employed in this country. The only species of *Jatropha* acknowledged as officinal in our Pharmacopœia is the *J. Manihot*, which yields the *tapioca* of the shops. A number of botanists, following Kunth, place this plant in a new genus separated from *Jatropha*, and named *Janipha*, from the Indian designation of another species of the genus. The following is the generic character of *Janipha* given by Lindley, from A. de Jussieu. "*Flowers* monœcious. *Calyx* campanulate, five-parted. *Petals* none. *MALE*. *Stamens* ten; filaments unequal, distinct, arranged around a disk. *FEMALE*. *Style* one. *Stigmas* three, consolidated into a rugose mass. *Capsule* three-coccus."

Jatropha Manihot. Willd. *Sp. Plant.* iv. 562. *Janipha Manihot*. Curtis's *Bot. Mag.* 3071. This is the *cassava* plant of the West Indies, the *mandioca* or *tapioca* of Brazil. It is a shrub about six or eight feet in height, with a very large, white, fleshy, tuberous root, which often weighs thirty pounds. The stem is round, jointed, and furnished at its upper part with alternate petiolate leaves, deeply divided into three, five, or seven oval lanceolate, very acute lobes, which are somewhat wavy upon their borders, of a deep green colour on their upper surface, glaucous and whitish beneath. The flowers are in axillary racemes.

The *Jatropha Manihot* is a native of South America, and is cultivated extensively in the West Indies, Brazil, and other parts of Tropical America, for the sake of its root, which is much employed as an article of food. The plant is of quick growth, and the root arrives at perfection in about eight months. There are two varieties, distinguished by the names of *sweet* and *bitter*. The root of the former may be eaten with impunity; that of the latter, which is most extensively cultivated, abounds in an acrid milky juice, which renders it highly poisonous if eaten in the recent state. By MM. Henry and Boutron-Charlard, it has been ascertained that the bitter cassava owes its poisonous properties to the presence of hydrocyanic acid. (*Journ. de Pharm.* xxii. 119.) Both varieties contain a large proportion of starch. The root is prepared for use by washing, scraping, and grating or grinding it into a pulp, which, in the case of the bitter variety, is submitted to pressure so as to separate the deleterious juice. It is now in the state of meal or powder, which is made into bread, cakes, or puddings. As the poisonous principle is volatile, the portion which may have remained in the meal is entirely dissipated by the heat employed in cooking. The preparation denominated *tapioca* among us is obtained from the expressed juice. This, upon standing, deposits a powder, which, after repeated washings with cold water, is nearly pure starch. It is dried by exposure to heat, which renders it partly soluble in cold water, and enables it to assume the consistence by

which it is characterized. When dried without heat, it is pulverulent, and closely resembles the fecula of arrow-root.

Tapioca is in the form of irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue colour when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch-granules by heat. Examined under the microscope, the granules appear partly broken, partly entire. The latter are mullar-shaped, about the two-thousandth of an inch in diameter, more uniform in size than the granules of most other varieties of fecula, with a distinct hilum which is surrounded by rings, and cracks in a stellate manner. The tapioca meal, called sometimes Brazilian arrow-root, and by the French *moussache*, is the fecula dried without heat. Its granules are identical with those already described. Being nutritious, and at the same time easy of digestion, and destitute of all irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon juice and sugar will usually be found grateful additions; and in low states of disease or cases of debility, it may be advantageously impregnated with wine and nutmeg or other aromatic.

A factitious tapioca is found in the shops, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca*. W.

LEONTODON. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ-Cichoraceæ, *De Candolle*; Cichoraceæ, *Lindley*.

Gen. Ch. Receptacle naked. *Calyx* double. *Seed-down* stipitate, hairy. *Willd.*

Leontodon Taraxacum. Willd. *Sp. Plant.* iii. 1544; Woodv. *Med. Bot.* p. 39. t. 16. *Taraxacum Dens-leonis*. De Cand. *Prodrom.* vii. 145. The dandelion is an herbaceous plant, with a perennial, fusiform root. The leaves, which spring immediately from the root, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine green colour. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-coloured flower, which closes in the evening, and expands with the returning light of the sun. The calyx is smooth and double, with the outer scales bent downwards. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is convex and punctured. The seed-down is stipitate, and at the period of maturity, is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the seeds attached.

This species of *Leontodon* grows spontaneously in most parts of the globe. It is abundant in this country, adorning our grass-plats and pasture grounds with its bright yellow flowers, which, in moist places, show them-

selves with the first opening of spring, and continue to appear till near the close of summer. All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young, and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and on the continent of Europe are sometimes used as a salad. When older and of their natural colour, they are medicinal, and have been adopted as officinal by the Dublin College. The other authorities recognise only the root, which is by far the most efficacious part. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness by drying; and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter. The juice of the root is thin and watery in the spring; milky, bitter, and spontaneously coagulable in the latter part of summer and autumn; and sweet and less bitter in the winter, when affected by the frost. The months of July, August, and September are, therefore, the proper period for collecting it.

The fresh full-grown root of the dandelion is several inches in length, as thick as the little finger, or thicker, round and tapering, somewhat branched, of a light brown colour externally, whitish within, having a yellowish ligneous cord running through its centre, and abounding in a milky juice. In the dried state it is much shrunk, wrinkled longitudinally, brittle, and when broken presents a shining somewhat resinous fracture. It is without smell, but has a sweetish, mucilaginous, bitterish, herbaceous taste. Its active properties are yielded to water by boiling, and do not appear to be injured in the process. The milky juice, examined by John, was found to contain bitter extractive, gum, caoutchouc, saline matters, a trace of resin, and a free acid. Besides these ingredients, starch, or inulin, and saccharine matter exist in the root. A crystallizable principle has been extracted from the juice of the root by M. Pollex, who has named it *taraxacin*. It is bitter and somewhat acrid, fusible but not volatile, sparingly soluble in cold water, but very soluble in boiling water, alcohol, and ether. It is obtained by boiling the milky juice in distilled water, filtering the concentrated liquor, and allowing it to evaporate spontaneously in a warm place. The taraxacin crystallizes, and may be purified by repeated solution and crystallization in alcohol or water. (*Pharm. Journ. and Transact.* i. 425.)

Medical Properties and Uses. Taraxacum is slightly tonic, diuretic, and aperient; and is thought to have a specific action upon the liver, exciting it when languid to secretion, and resolving its chronic engorgements. It has been much employed in Germany, and is a popular remedy with many practitioners in this country. The diseases to which it appears to be especially applicable, are those connected with derangement of the hepatic system, and of the digestive organs generally. In congestion and chronic inflammation of the liver and spleen, in cases of suspended or deficient biliary secretion, and in dropsical affections dependent on obstruction of the abdominal viscera, it is capable of doing much good, if employed with a due regard to the degree of excitement. Our own experience is decidedly in its favour. An irritable condition of the stomach and bowels, and the existence of acute inflammation, contra-indicate its employment. It is usually given in the form of extract or decoction. (See *Decoctum Taraxaci* and *Extractum Taraxaci*.) Bitartrate of potassa is sometimes added to the decoction when an aperient effect is desired; and aromatics will occasionally be found useful in correcting a tendency to griping or flatulence.

The term *turpentine* is now generally applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar essential oil, called *oil of turpentine*. They are generally procured from different species of pine, fir, or larch, though other trees afford products which are known by the same general title, as for instance the *Pistacia Terebinthus*, which yields the Chian turpentine. Some of the French writers extend the name of turpentine to other juices consisting of resin and essential oil, without benzoic or cinnamic acid, as copaiba, balm of Gilead, &c. We shall describe particularly, in this place, only the officinal turpentines. A brief botanical view of the plants from which they are respectively derived, will be in accordance with the plan of the work. It is proper first to observe that the original genus *Pinus* of Linnæus has been divided into the three genera, *Pinus*, *Abies*, and *Larix*, which are now very generally recognised, though Lindley unites the two latter in his *Flora Medica*.

PINUS. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Pinaceæ or Coniferæ.

Gen. Ch. Flowers monœcious. MALES. *Catkins* racemose, compact, and terminal; squamose; the scales staminiferous at the apex. *Stamens* two; the *anthers* one-celled. (*Pereira's Mat. Med.* from *Bot. Gall.*)

1. *Pinus palustris*. Willd. *Sp. Plant.* iv. 499.—*P. Australis*. Michaux, *N. Am. Sylv.* iii. 133. "Leaves in threes, very long; stipules pinnatifid, ramentaceous, persistent; strobiles subcylindrical, armed with sharp prickles."

This is a very large indigenous tree, growing in dry sandy soils, from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of this height. The leaves are about a foot in length, of a brilliant green colour, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States, are *long-leaved pine*, *yellow pine*, and *pitch pine*; but the first is most appropriate, as the last two are applied also to other species. This tree furnishes by far the greater proportion of turpentine, tar, &c., consumed in the United States, or sent from this to other countries. (See *Pix Liquida*.)

2. *Pinus Tæda*. Willd. *Sp. Plant.* iv. 498; Michaux, *N. Am. Sylv.* iii. 156. "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

This is the *loblolly*, or *old field pine* of the Southern States. It is abundant in Virginia, where it occupies the lands which have been exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide-spreading top. The leaves are about six inches long, and of a light green colour. It yields turpentine in abundance, but less fluid than that which flows from the preceding species.

3. *Pinus sylvestris*. Willd. *Sp. Plant.* iv. 494; Woodv. *Med. Bot.* p. 1. t. 1; Michaux, *N. Am. Sylv.* iii. p. 125. "Leaves in pairs, rigid; strobiles ovate-conical, of the length of the leaves; scales echinate."

This species of pine, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits the northern and mountainous parts of Europe. In Great Britain it is called the *wild pine*, or *Scotch fir*; the latter name having been applied to it from its abundance in the mountains of Scotland. It yields a considerable proportion of the common European turpentine.

Besides the pines above described, various others yield medicinal products. The *Pinus maritima* (*Pinus Pinaster* of Aiton and Lambert), growing in the southern and maritime parts of Europe, yields much of the turpentine, pitch, and tar consumed in France, and is admitted among the officinal plants in the French Codex. From the branches of the *Pinus Pumilio*, which inhabits the mountains of Eastern and South-eastern Europe, a terebinthinate juice exudes spontaneously, called *Hungarian balsam*. The *Pinus Cembra*, or *Siberian stone-pine* of the Alps and Carpathian mountains, is said to afford the product called *Carpathian balsam*; and the seeds both of that species, and the *Pinus Pineæ*, or *stone-pine* of the South of Europe and North of Africa, are used in Europe in desserts, under the name of *pine nuts*. The *Pinus rigida* or *pitch pine* of this

country, and probably others besides those mentioned are sometimes employed in the preparation of tar.

ABIES. See PIX ABIETIS.

Abies balsamea. Lindley, *Flor. Med.* p. 554.—*A. balsamifera*, Michaux, *N. Am. Sylv.* iii. 191.—*Pinus balsamea*. Willd. *Sp. Plant.* iv. 504. "Leaves solitary, flat, emarginate or entire, glaucous beneath, somewhat pectinate, sub-erect above, recurved spreading; cones cylindrical, erect; bractes abbreviate, obovate, conspicuously mucronate, sub-serrulate."

This is the *American silver fir*, or *balm of Gilead tree* inhabiting Canada, Nova Scotia, Maine, and the mountainous regions further to the south. It is an elegant tree, seldom rising more than forty feet in height, with a tapering trunk, and numerous branches which diminish in length in proportion to their height, and form an almost perfect pyramid. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish colour, and covered with a resinous exudation which gives them a glossy, rich, and beautiful appearance. It is from this tree that the *Canada balsam* is obtained.

Several other species of *Abies* are officinal. The *A. excelsa* of Europe, and *A. Canadensis* of the United States, have already been described as the sources respectively of Burgundy and Canada pitch. (See *Pix Abietis*, and *Pix Canadensis*.) The *A. Picea* (*Abies pectinata* of De Candolle, *A. taxifolia* of the French Codex, *Pinus Picea* of Linnæus), or *European silver fir*, growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the *Strasburg turpentine*, which is much used in some parts of Europe. The *Abies nigra* (*Pinus nigra*), or *black spruce* of this country yields a product, which, though not recognised by the Pharmacopœia, is considerably employed. The substance alluded to is the *essence of spruce*, prepared from the young branches, by boiling them in water, and evaporating the decoction. It is a thick liquid, having the colour and consistence of molasses, with a bitterish, acidulous, astringent taste. It is much used in the preparation of the beverage commonly known by the name of *spruce beer*, which is a pleasant and wholesome drink in summer, and useful in long sea-voyages as a preventive of scurvy.*

Larix. *Sex. Syst.* Monœcia Monadelphica.—*Nat. Ord.* Pinacæ or Coniferæ.

Gen. Ch. As in *Abies*, except that the *Cotyledons* are simple, and never lobed; the *Cones* lateral; the *Leaves*, when first expanding, in tufted fascicles, becoming somewhat solitary by the elongation of the new branch. (*Pereira's Mat. Med.* from *Bot. Gall.*)

Larix europæa. De Cand. *Flor. Fr.* 2064.—*Abies Larix*. Lamb. *Illustr.* t. 785. f. 2.—*Pinus Larix*. Willd. *Sp. Plant.* iv. 503; *Woodv. Med. Bot.* p. 7. t. 4. "Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bractes panduriform."

The *European larch* is a large tree inhabiting the mountains of Siberia, Switzerland, Germany, and the East of France. It yields the *Venice turpentine* of commerce, and a peculiar sweetish substance, called in France *Briançon manna*, which exudes spontaneously, and concretes upon its bark. When the larch forests of Russia take fire, a juice exudes from the

* The following is the formula usually followed. Take of essence of spruce half a pint; pimento bruised, ginger bruised, hops, each four ounces; water three gallons. Boil for five or ten minutes; then strain, and add of warm water eleven gallons; yeast a pint; molasses six pints. Mix and allow the mixture to ferment for twenty-four hours.

trunk during their combustion, which concretes, and is called *Orenburgh gum*. It is wholly soluble in water. (*Lindley, Flor. Med.*)

PISTACIA. See MASTICHE.

Pistacia Terebinthus. Willd. *Sp. Plant.* iv. 752; Woodv. *Med. Bot.* p. 29. t. 12. This is a small tree with numerous spreading branches, bearing alternate, pinnate leaves, which consist of three or four pairs of ovate lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are diœcious, small, and in branching racemes. This is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the turpentine obtained from the tree.

We shall treat of the several varieties of turpentine under distinct heads.

1. WHITE TURPENTINE.

Térébenthine de Boston, *Fr.*

The common *American* or *white turpentine* (*Terebinthina*, U.S.) is procured chiefly from the *Pinus palustris*, partly also from the *Pinus Tæda*, and perhaps some other species inhabiting the Southern States. In former times, large quantities were collected in New England; but the turpentine trees of that section of the Union are said to be nearly exhausted; and our commerce is almost exclusively supplied from North Carolina, and the south-eastern parts of Virginia. The following is the process for obtaining the turpentine as described by Michaux. During the winter months, excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground. Into these the juice begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumnal months. The liquid is removed from these excavations as they fill, and transferred into casks, where it gradually thickens, and ultimately acquires a soft solid consistence. Very large quantities are thus annually procured, sufficient not only to supply the whole consumption of this country, but also to furnish a valuable export.

White turpentine, as found in our shops, is yellowish-white, of a peculiar somewhat aromatic odour, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence which varies with the temperature. In the middle of summer it is almost semi-fluid and very adhesive, though brittle; in the winter it is often so firm and hard, as to be incapable of being made into pills without heat. Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about seventeen per cent. of essential oil. It is apt to contain small pieces of bark, wood, or other impurity.

2. COMMON EUROPEAN TURPENTINE.

Térébenthine de Bordeaux, Térébenthine commune, *Fr.*; Gemeiner Terpentin, *Germ.*; Trementina comune, *Ital.*; Trementina comun, *Span.*

This is the *Terebinthina Vulgaris* of the London Pharmacopœia. It is furnished by several species of pine; but chiefly by the *Pinus sylvestris* and *Pinus maritima* (*P. Pinaster* of Aiton). From the latter tree, it is obtained largely in the maritime districts of the Southwest of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce *Bordeaux turpentine*. The process for procuring it consists simply in making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out in small troughs, or in holes dug at the foot of the tree. It is purified by heating, and filtering it

through straw, or by exposing it to the sun in a barrel, through holes in the bottom of which the melted turpentine escapes. Thus prepared, it is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like those of thickened honey. As found in European commerce it often consists wholly of this latter portion. It speedily hardens upon exposure to the air in thin layers. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two of the turpentine. (Guibourt, *Journ. de Pharm.* xxv. 499.) It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and resin. We do not import it into this country. The substance which the French call *galipot* or *barras*, is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. (Thenard.) This, when purified by melting with water and straining, takes the name of *yellow* or *white pitch*, or *Burgundy pitch*. When turpentine has been deprived of its oil by distillation, the resin which remains is called *rosin*, and sometimes *colophony*, from the Ionian city of that name, where it was formerly prepared. It is the yellow resin (*resina flava*) of the former London Pharmacopœia. White resin (*resina alba*) is prepared by incorporating this, while in fusion, with a certain proportion of water. Tar (*Pix Liquida*) is the turpentine extracted from the wood by a slow combustion, and chemically altered by the heat. Common pitch (*Pix Nigra* or *Resina Nigra*) is the solid residue left after the evaporation by boiling of the liquid parts of tar. (See these titles respectively.)

3. CANADIAN TURPENTINE.

Canada balsam, Balsam of fir; Baume de Canada, *Fr.*; Canadischer Balsam, Canadischer Terpentint, *Germ.*; Trementina del Canada, *Ital.*

This is the product of the *Abies balsamea*, and is collected in Canada and the State of Maine. It is procured, according to Michaux, by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. When fresh, it is colourless or slightly yellowish, transparent, of the consistence of thin honey, very tenacious, of a strong agreeable odour, and a bitterish, somewhat acrid taste. By time and exposure it becomes more yellow and thicker, and at last assumes a solid consistence. It is usually brought into market in bottles, and is kept in the shops under the name of *Canada balsam* or *balsam of fir*. In Europe, it is sometimes called *balm of Gilead*, from its supposed resemblance to that celebrated medicine. The term *balsam*, as at present understood, is improperly applied to it; as it contains no benzoic acid, and is in fact a true turpentine, consisting chiefly of resin and essential oil. Bonastre obtained from 100 parts of Canada turpentine, 18.6 parts of volatile oil, 40.0 of resin easily dissolved by alcohol, 33.4 of sub-resin of difficult solubility in that fluid, 4.0 of caoutchouc similar to sub-resin, and 4.9 of bitter extractive and salts, besides traces of acetic acid. There is reason to believe that *Strasburg turpentine* is sometimes sold for it in the shops.

4. VENICE TURPENTINE.

Térébenthine de mélèze, Térébenthine de Venise, *Fr.*; Venetianischer Terpentint, *Germ.*; Trementina di Venezia, *Ital.*; Trementina de Venecia, *Span.*

This turpentine received its name from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and the French province of Dauphiny, from the *Larix Europæa* or larch, which grows abundantly upon the Alps and the Jura mountains. The

peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs, placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice Turpentine is a viscid liquid, of the consistence of honey, flowing with difficulty, cloudy or imperfectly transparent, of a yellowish or slightly greenish colour, a strong not disagreeable odour, and a warm bitterish and very acrid taste. It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. (Guibourt, *Journ. de Pharm.* xxv. 500.) What is sold under the name of Venice turpentine, in our shops, is usually quite brown, and is said to be a factitious substance, prepared by dissolving rosin in oil of turpentine. Dr. A. T. Thomson states that much of the Venice turpentine of the shops of London is obtained from America. It is probably the same preparation as that which passes under the name in this country.

5. CHIAN TURPENTINE.

Térébenthine de Chio, *Fr.*; Cyprischer Terpentin, *Germ.*; Trementina Cipria, *Ital.*

This variety of turpentine is collected chiefly in the island of Chio or Scio, by incisions made during the summer in the bark of the *Pistacia Terebinthus*. The juice, flowing from the wounds, falls upon smooth stones placed at the foot of the tree, from which it is scraped with small sticks, and allowed to drop into bottles. The annual product of each tree is very small; and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious liquid, of a greenish-yellow colour, a peculiar penetrating odour more agreeable than that of the other substances of the same class, and a mild taste without bitterness or acrimony. It leaves a glutinous residue when treated with strong alcohol. (Guibourt.) On exposure to the air it speedily thickens, and ultimately becomes concrete and hard, in consequence of the loss of its volatile oil.

Besides the turpentines mentioned, various others are noticed in books on materia medica, though not found in the shops of this country. There is the *Strasburg turpentine*, much used in France, and obtained from the *Abies Picea* (*Abies pectinata* of De Candolle), or European silver fir, which grows on the mountains of Switzerland and Germany, and bears a close resemblance, as well in its appearance as its product, to the *Pinus balsamea* of Canada; the *Damarra turpentine*, which speedily concretes into a very hard resin, and is derived from the *Pinus Damarra* of Lambert, the *Agathis Damarra* of Richard, growing in the East India islands; and the *Dombeya turpentine*, a glutinous, milky-looking fluid of a strong odour and taste, derived from the *Dombeya excelsa*, the *Araucaria Dombeyi* of Richard, which inhabits Chili, and is said to be identical with the Norfolk Island pine. These, with one or two other turpentines scarcely known or having a doubtful claim to the title, are all that belong properly to this class of vegetable products.

General Properties. The turpentines resemble each other in odour and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation

a volatile oil, well known as the *oil of turpentine*, and leave a residue consisting exclusively of resin. (See *Öleum Terebinthinæ* and *Resina*.) A minute proportion of succinic acid passes over with the oil. From the experiments of M. Faure, of Bordeaux, it appears, that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia (*Journ. de Chim. Med.* 1830, p. 94.); and, according to M. Thierry, the same result is obtained by the addition of one part of hydrate of lime to thirty-two parts of the common European turpentine. (*Journ. de Pharm. 3ème Série*, i. 315.)

Medical Properties and Uses. The effects of the turpentines upon the system are dependent entirely on their essential oil. They are stimulant, diuretic, anthelmintic, and in large doses laxative. When taken internally, or applied to the skin, they communicate a violet odour to the urine, and if continued for some time produce an irritation of the mucous membrane of the urinary passages, amounting frequently to strangury. The last effect is less apt to be experienced when they operate upon the bowels. Externally applied they act as rubefacients. Their medical virtues were known to the ancients. At present they are less used than formerly, having been superseded by their volatile oil. They are, however, occasionally prescribed in leucorrhœa, gleet, and other chronic diseases of the urinary passages; in piles and chronic inflammations or ulcerations of the bowels; in chronic catarrhal affections; and in various forms of rheumatism, especially sciatica and lumbago. The white turpentine is usually employed in this country.

They may be given in the shape of pill made with powdered liquorice root; or in emulsion with gum Arabic or yolk of egg, loaf sugar, and water; or in electuary formed with sugar or honey. Their dose is from a scruple to a drachm. In the quantity of half an ounce or an ounce, triturated with the yolk of an egg, and mixed with half a pint of mucilaginous liquid, they form an excellent injection in cases of ascarides, and of constipation attended with flatulence.

TESTA. U.S.

Oyster-shell.

“The shells of *Ostrea edulis*.”

Off. Syn. TESTÆ. *Lond.*

Ecailles des huitres, *Fr.*; Austerschalen, *Germ.*; Gusci della ostriche, *Ital.*; Cascaras, *Span.*

The common oyster is the *Ostrea edulis* of naturalists, an animal belonging to the class *Vermes*, order *Testacea*. It is found in many parts of the world, and is particularly abundant on our own coast, and in the bays of our large rivers. It consists of a soft pulpy portion, comprising the vital organs of the animal, enclosed in a hard bivalve shell, of the nature of mother-of-pearl. The flesh of the oyster forms a very digestible and nutritious article of food, particularly suited to convalescents; but the shell only is officinal.

Properties. Oyster-shells are too familiarly known to require description. They are made up, like other mother-of-pearl shells, of alternate layers of earthy matter, and animal matter of the nature of coagulated albumen. According to the analysis of Bucholz and Brandes, their exact constituents are

carbonate of lime 98·6, phosphate of lime 1·2, animal matter 0·5, alumina (accidental) 0·2=100·5. Thus it appears that the animal matter is present in but small amount. When calcined or burnt, the animal matter and carbonic acid are dissipated, and the shells are converted into a species of lime, called oyster-shell lime.

Crab stones (*crabs' eyes*) and crabs' claws are both forms of carbonate of lime, resembling oyster-shell in containing a small proportion of animal matter. They were formerly officinal in the Edinburgh Pharmacopœia, but were very properly omitted upon the recent revision of that work. They will be noticed in the Appendix.

Pharmaceutical Uses. Oyster-shells require to be reduced to an impalpable powder, before they are fit for medicinal employment; and their preparation in this way constitutes their sole pharmaceutical use. When thus prepared, they form the *Testa Præparata*, under which head their medicinal properties will be noticed.

TOLUTANUM. U. S.

Balsam of Tolu.

“The juice of *Myroxylon Toluiferum*. *Richard.*” *U. S.*

Off. Syn. BALSAMUM TOLUTANUM. *Myroxylon peruiferum*. *Balsamum concretum*. *Lond.*; BALSAMUM TOLUTANUM. Concrete balsamic exudation of *Myrospermum toluiferum*.” *Ed.*; TOLUIFERA BALSAMUM. *Resina. Dub.*

Balsam of Tolu; Baume de Tolu, *Fr.*; Tolubalsam, *Germ.*; Balsamo del Tolu, *Ital.*; Balsamo de Tolu, *Span.*

MYROXYLON. See MYROXYLON.

Till recently, the tree from which this balsam is derived, retained the name of *Toluifera Balsamum*, given to it by Linnæus; but it is now admitted that the genus *Toluifera* was formed upon insufficient grounds; and botanists agree in referring the Tolu balsam tree to the *Myroxylon*, or *Myrospermum* of De Candolle. Ruiz, one of the authors of the *Flora Peruviana*, considers it identical with the *Myroxylon Peruiferum*; and his opinion has been adopted by some other writers. M. Achille Richard, however, thinks it a distinct species, and has appropriately denominated it *Myroxylon Toluiferum*, a title which is recognised in the Pharmacopœia of the United States. Sprengel and Humboldt also consider it a distinct species of *Myroxylon*. According to Richard, who had an opportunity of examining specimens brought from South America by Humboldt, the leaflets of the *M. Peruiferum* are thick, coriaceous, acute, and blunt at the apex, and all equal in size; while in the *M. Toluiferum* the leaflets are thin, membranous, obovate, with a lengthened and acuminate apex, and the terminal one is longest. The *M. Peruiferum* is found in Peru and the southern parts of New Granada; the *M. Toluiferum* grows in Carthagera, and abounds especially in the neighbourhood of Tolu. The wood of the latter species, according to Humboldt, is of a deep red colour, has a delightful balsamic odour, and is much used for building. It is not improbable, that the two balsams known in the shops by the respective names of Peru and Tolu, differ more in the mode by which they are procured, than in the character of the trees which afford them.

The balsam of Tolu is procured by making incisions into the trunk of the tree. The juice as it exudes is received in vessels of various kinds, in

which it is allowed to concrete. It is brought from Carthageria in calabashes or baked earthen jars of a peculiar shape, and sometimes in glass vessels.

Properties. As first imported, it has a soft, tenacious consistence, which varies considerably with the temperature. By age it becomes hard and brittle like resin. It is shining, translucent, of a reddish or yellowish-brown colour, a highly fragrant odour, and a warm, somewhat sweetish and pungent, but not disagreeable taste. Exposed to heat, it melts, inflames, and diffuses an agreeable odour while burning. It is entirely dissolved by alcohol and the essential oils. Boiling water extracts its benzoic acid. Distilled with water it affords a small proportion of volatile oil; and if the heat be continued, benzoic acid sublimes. Mr. Hatchett states, that when dissolved in the smallest quantity of solution of potassa, it loses its own characteristic odour, and acquires that of the clove-pink. Its ingredients are resin, benzoic and cinnamic acids, and volatile oil, the proportions of which vary in different specimens. Frémy discovered in it cinnamic acid, but was wrong in supposing that it contained no benzoic acid, as has been proved by M. Deville. (*Journ. de Pharm.* xxvii. 638.) Guibourt observed that it contains more benzoic acid, and is less odorous in the solid form; and thinks that the acid is increased at the expense of the oil. Trommsdorff obtained 88 per cent. of resin, 12 of acid, and only 0.2 of volatile oil.

Medical Properties and Uses. Balsam of Tolu is a stimulant tonic, with a peculiar tendency to the pulmonary organs. It is given with some advantage in chronic catarrh and other pectoral complaints, in which a gently stimulating expectorant is demanded; but should not be prescribed until after the reduction of inflammatory action. Independently of its medical virtues, its pleasant flavour renders it a popular ingredient in expectorant mixtures. Old and obstinate coughs are said to be sometimes greatly relieved by the inhalation of the vapour proceeding from an ethereal solution of this balsam.

From ten to thirty grains may be given at a dose, and frequently repeated. The best form of administration is that of emulsion, made by triturating the balsam with mucilage of gum Arabic and loaf sugar, and afterwards with water.

POTENTILLA. Sex. Syst. Icosandria Polygynia.—Nat. Ord. Rosaceæ.

Gen. Ch. *Calyx* with a concave tube, a four or five-cleft limb, and four or five bractlets. *Petals* four or five. *Stamens* numerous. *Carpels* numerous, with a lateral style, on a procumbent, persistent, capitate, juiceless receptacle. *Seed* appended. Herbs or undershrubs, with compound leaves, stipules adnate to the petiole, and white, yellow, rarely red flowers. (*De Candolle.*)

Potentilla Tormentilla. Sibthorp. *Fl. Ox.* 162; Lindley, *Flor. Med.*

225.—*Tormentilla erecta*. Willd. *Sp. Plant.* ii. 1112; Woodv. *Med. Bot.* p. 503. t. 181.—*T. Officinalis*. Smith, *Flor. Brit.* The tormentil, or sept-foil, is a small perennial plant, very common throughout Europe. The stems, which rise about six or eight inches in height, from a woody root, are slender, more or less erect, branching towards the top, and furnished with sessile leaves, which on the stalk usually consist of seven, on the branches of five, digitate, elliptical, villous, deeply serrated leaflets, three of which are larger than the others. The flowers are small, yellow, and solitary upon axillary peduncles. All parts of the plant are astringent, especially the root, which is the part employed. It is gathered in spring.

Properties. The root of tormentil is cylindrical or roundish, rather larger above than at the lower extremity, an inch or two in length, about as thick as the finger, knotty, sometimes contorted, brown or blackish externally, and reddish within. It has a slight aromatic odour, and a very astringent taste. Tannin is an abundant constituent. There is also a red colouring principle, soluble in alcohol, but insoluble in water. Besides these ingredients, Meissner found resin, cerin, myricin, gummy extractive, gum, extractive, lignin, water, and a trace of volatile oil. The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. It yields all its medical virtues to boiling water.

Medical Properties and Uses. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. We seldom, however, employ it in this country, having indigenous plants of equal virtue. It may be given in substance, decoction, or extract. The dose of the powder is from thirty grains to a drachm.

Off. Syn. RHUS TOXICODENDRON. *Folia*. Dub.

Sumac venéneux, *Fr.*; Gift-Sumach, *Germ.*; Albero del veleno, *Ital.*

RHUS. See RHUS GLABRUM.

Admitting, as appears generally to be done at present, that the *Rhus Toxicodendron* and *Rhus radicans* of Linnæus, are mere varieties of the same plant, there are three indigenous species of *Rhus* which possess poisonous properties—the one above mentioned, the *R. Vernix*, commonly known by the name of *swamp sumach* or *poison sumach*, and the *R. pumilum* of the Southern States. Though the first only is designated in the Pharmacopœia, we shall briefly describe the three species, as their medical effects are probably similar, and their operation upon the system such that the plants should be known to every practitioner.

1. *Rhus radicans*. Willd. *Sp. Plant.* i. 1481; Bigelow, *Am. Med. Bot.* iii. 17.—*R. Toxicodendron*. Pursh, *Fl. Am. Sept.* p. 205. Though Elliott and Nuttall consider the *R. radicans* and *R. Toxicodendron* as distinct species, the weight of botanical authority is on the other side, and Bigelow declares that he has “frequently observed individual shoots from the same stock, having the characters of both varieties.” The difference, however, in their appearance, is sufficiently striking to have led to the adoption of

different common names, the *R. radicans* being usually called *poison vine*, and the *R. Toxicodendron*, *poison oak*. The former has a climbing stem, rising to a great height upon trees, rocks, and other objects, to which it adheres by strong rooting fibres, which it throws out from its sides. The leaves, which stand upon long footstalks, are ternate, with broad ovate or rhomboidal, acute leaflets, smooth and shining on both sides, sometimes slightly hairy on the veins beneath, entire, or irregularly lobed and toothed. The flowers are small, greenish-white, diœcious, and grow in lateral, usually axillary panicles, or compound racemes. The male flowers have five stamens, and the rudiments of a style; the female, which are of only half the size and on a different plant, have abortive stamens, and a short erect style, standing on a roundish germ, and terminating in three stigmas. The fruit consists of roundish, pale-green or whitish berries.

The *R. Toxicodendron*, or poison-oak, has the form of a shrub from one to three feet high, with leaflets angularly indented, and pubescent beneath. But this character of the foliage is probably not constant; and the stunted growth may be owing to peculiarities of situation. Dr. Bigelow states that the young plants of the *R. radicans* do not put forth rooting fibres until they are several years old, and that they are influenced in this respect by the contiguity of supporting objects.

This species of *Rhus* grows in woods, fields, and along fences from Canada to Georgia. It flowers in June and July. When wounded, it emits a milky juice, which becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it.

The juice applied to the skin frequently produces inflammation and vesication; and the same poisonous property is possessed by a volatile principle which escapes from the plant itself, and produces in persons who come into its vicinity an exceedingly troublesome erysipelatous affection, particularly of the face. Itching, redness, a sense of burning, tumefaction, vesication, and ultimate desquamation, are some of the attendants of this poisonous action. The swelling of the face is sometimes so great as almost entirely to obliterate the features. The effects are experienced soon after exposure, and usually begin to decline within a week. A light cooling regimen, with saline purgatives, and the local use of cold lead water, are the best remedies. All persons are not equally liable to the affection, and the great majority are wholly insusceptible of it from any ordinary exposure.

2. *Rhus Vernix*. Willd. *Sp. Plant.* i. 1479; Bigelow, *Am. Med. Bot.* i. 96. The *swamp sumach* is a beautiful shrub or small tree, usually ten or fifteen feet high, but sometimes rising thirty feet. The bark of the trunk is dark gray, of the branches lighter, of the extreme twigs and petioles beautifully red. The leaves are pinnate, with four or five pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuated, acuminate, smooth, and except the one at the end, nearly sessile. The flowers, as in the preceding species, are diœcious. They are very small, greenish, and arranged in loose axillary panicles. The berries are small, roundish, and greenish-white.

The tree grows in swamps and low grounds, from Canada to Carolina, and flowers in June and July. It is thought to be identical with a species of *Rhus* which grows in Japan, and furnishes a fine black varnish, much used in that country. Dr. Bigelow found that the opaque whitish juice which exudes from our native plant when wounded, and which becomes permanently black on exposure, may be made to afford a brilliant, glossy, durable varnish, by boiling it sufficiently before applying it.

The *Rhus Vernix* produces much more powerfully than the *R. radicans*, the poisonous effects already described. Persons coming within its influence are much more apt to be affected with the poison, and generally suffer more severely. The whole body is sometimes enormously swollen, and the patient for many days scarcely able to move; but the complaint almost always spontaneously subsides without destroying life. As in the former instance, the susceptibility to the influence of the poison is exceedingly various, and some persons may handle the plant with perfect impunity.

3. *Rhus pumilum*. Michaux, *Flor. Americ.* i. 182. This is a southern species, growing in upper Carolina, and not more than a foot in height. It is characterized by its pubescent branches and petioles; its pinnate leaves, with many pairs of oval, nearly acuminate, incised dentate leaflets, downy beneath; and by its silky fruit. According to Pursh it is the most poisonous of the genus.

It is probable that all parts of the *Rhus radicans* (*R. Toxicodendron*) are possessed of active properties; but the leaves only are directed in the Pharmacopœia, under the title of *Toxicodendron*. These are inodorous, have a mawkish acrid taste, and yield their virtues to water. The presence of tannin and gallic acid has been detected in them; but they have not been accurately analyzed.

Medical Properties and Uses. These leaves appear to be stimulant and narcotic, producing when swallowed more or less irritation of the stomach and bowels, and promoting the secretory function of the skin and kidneys. Orfila found them to act in the manner of the acrid poisons, and to produce a stupifying effect upon the nervous system. They were successfully used by Du Fresnoy, in France, in the cure of obstinate cutaneous diseases. Dr. Anderson of Hull in England, effected cures with the medicine in several cases of palsy. A sense of heat and pricking, with irregular twitchings, were excited by it in the affected parts. Dr. Horsfield, and other physicians of this country, have used it in consumption and dropsy, but not with any very encouraging success.

The dose of the leaves recommended by Dr. Anderson, was half a grain or a grain three times a day; but this is much too small. Dr. Duncan gave it in larger doses, with little other than a laxative effect. Dr. Horsfield administered a teacupful of the strong infusion without disadvantage. In France the extract is recommended in doses of fifteen or twenty grains, repeated two or three times a day, and gradually increased to one or two drachms. Some of Du Fresnoy's patients took an ounce without effect. The probability is, that the active principle is volatile, and that the extract is less efficient than the leaves themselves. The risk of experiencing the poisonous effects of the plant upon the system, will probably prevent its extensive employment as a remedy, unless it should prove much more useful than the trials hitherto made give us reason to expect.

ASTRAGALUS. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Fabaceæ or Leguminosæ.

Gen. Ch. Legume two-celled, more or less gibbous, with the lower suture turned inwards. *Carina* blunt. *Loudon's Encyc. of Plants.*

Numerous species belonging to this genus yield a gummy matter having the properties of tragacanth. The drug known in commerce by that name was at first erroneously supposed to be obtained from the *A. Tragacantha* of Linnæus (*A. massiliensis* of Lamarek), which grows in the South of Europe and North of Africa, and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (*A. Creticus* of Lamarek) which grows in Crete and Ionia; and on that of Olivier to the *A. verus*, which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer*, which he found growing on Mount Libanus in Syria, and from which tragacanth exudes, though not that of commerce. Siéber denies that any one of these species yields the officinal tragacanth, which he ascribes to the *A. aristatus* growing in Anatolia, especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the *A. aristatus* of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (*Merat and De Lens.*) Professor Lindley has lately received two specimens of plants, said to be those which furnish tragacanth in Turkistan, one of which proves to be the *A. gummifer* of Labillardière, which was said to yield a white variety, and the other a new species which he calls *A. strobiliferus*, and which was said to yield a red and inferior product. The fact seems to be, that the commercial drug is collected from various sources; and it is affirmed that all the species of *Astragalus* with thorny petioles are capable of producing it. These form a natural group, and so closely resemble each other, that botanists have found some difficulty in distinguishing them. As the *A. verus* is designated in the Pharmacopœia of the United States, and that of the London College, we shall briefly describe it.

Astragalus verus. Olivier, *Voy. dans l'Empire Ottoman*, v. 342. pl. 44. This is a small shrub, not more than two or three feet high, with a stem an inch in thickness, and numerous very closely crowded branches, covered with imbricated scales, and spines which are the remains of former petioles. The leaves, which are little more than half an inch long, consist of several pairs of opposite, villous, stiff, pointed leaflets, with a midrib terminating in a sharp yellowish point. The flowers are papilionaceous, small, yellow, axillary, aggregate, and furnished with cottony bractes. This species yields the gum collected in Persia, and thence transmitted southward to India through Bagdad and Bassora, northward to Russia, and westward to Aleppo.

Tragacanth exudes spontaneously during the summer from the stems and branches, hardening as it exudes, and assuming various forms according to the greater or less abundance of the juice.

Properties. It is in tortuous, vermicular filaments, rounded or flattened, rolled up or extended, of a whitish or yellowish-white colour, somewhat translucent, resembling horn in appearance. Sometimes the pieces are irregularly oblong or roundish, and of a slightly reddish colour. It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar. The powder is very fine and white. Tragacanth has no smell, and very little taste. Its sp. gr. is 1.384. Introduced into water it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this

paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum Arabic, the other capable of swelling in water, but not dissolving. The former is said to differ from gum Arabic in affording no precipitate with silicate of potassa or sesquichloride of iron. (*Pereira's Mat. Med.*) The latter, which, according to Bucholz, constitutes 43 per cent. of tragacanth, is ranked by some among the peculiar proximate principles with the title of *tragacanthin*. It is probably identical with *bassorin*. It has the property of becoming blue with iodine, which is not the case with *bassorin*; but this property is ascribed to the presence of a small quantity of insoluble starch. According to M. Guerin, 100 parts of tragacanth contain 53·3 parts of arabin or pure gum, 33·1 of *bassorin* and insoluble starch, and 11·1 of water, and yield when burned 2·5 parts of ashes. To separate the soluble entirely from the insoluble part, requires agitation with separate portions of water, which are to be decanted and filtered; and the process is to be continued till water ceases to dissolve any thing. Berzelius considers tragacanth as a variety of mucilage. (See *Linum*.)

Medical Properties and Uses. Tragacanth is demulcent, but on account of its difficult solubility, is not often given internally. The great viscosity which it imparts to water, renders it useful for the suspension of heavy insoluble powders; and it is also employed in pharmacy to impart consistence to troches, for which it answers better than gum Arabic.

TRIOSTEUM. U. S. Secondary.

Fever-root.

“The root of *Triosteum perfoliatum*.” U. S.

TRIOSTEUM. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. Calyx five-cleft, persistent, nearly the length of the corolla; segments linear, acute. Corolla tubular, five-lobed, sub-equal, base, nectariferous, gibbous. Stigma somewhat five-lobed, capitate. Berry three-celled, three-seeded, crowned with the calyx. *Nuttall.*

Triosteum perfoliatum. Willd. *Sp. Plant.* i. 990; Bigelow, *Am. Med. Bot.* i. 90; Barton, *Med. Bot.* i. 59. This plant is indigenous and perennial. Several stems usually rise from the same root. They are simple, erect, round, hairy, fistulous, herbaceous, and from one to four feet high. The leaves are opposite, large, mostly connate, oval, acuminate, entire, abruptly narrowed at the base, and pubescent on their under surface. The flowers are of a dull purple colour, axillary, sessile, rarely solitary, sometimes in pairs, generally in triplets or five together in the form of whorls. The germ is inferior, and the style projects beyond the corolla, into the tube of which the stamens are inserted. The berry is oval and of a deep orange colour, and contains three hard, bony seeds.

The *fever-wort*, *fever-root*, or *wild ipecac*, as this plant is variously called, though not very abundant, is found in most parts of the United States, preferring a limestone soil and shady situations. Its flowers appear in June. The whole plant has a bitter taste; but the root is most active, and is the only official part.

It is horizontal, long, about three quarters of an inch in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish colour externally, whitish within, and furnished with fibres which may be considered as branches of the main root. When dry it is brittle and easily pulverized. It has a sickening odour and a bitter nauseous taste. Both water and alcohol take up its active properties, which are retained in the extract.

Medical Properties and Uses. Fever-root is cathartic, and in large doses emetic. The late Professor Barton observed it also to produce a diuretic effect. The bark of the root is the part which has been usually employed. In the quantity of twenty or thirty grains it ordinarily acts upon the bowels; and may be given alone or in combination with calomel at the commencement of fevers. The extract may be given in half the dose. W.

TRITICUM HYBERNUM. *Seminum farina. Dub.*

Wheat Flour.

Off. Syn. FARINA. *Triticum hybernum. Seminum Farina. Lond.; FARINA.* Flour of the seeds of *Triticum vulgare. Ed.*

Farine de froment, *Fr.*; Waizenmehl, *Germ.*; Farina di frumento, *Ital.*; Flor del trigo, *Acemite, Span.*

TRITICUM. Sex. Syst. Triandria Digynia.—*Nat. Ord.* Graminaceæ.

Gen. Ch. Calyx two-valved, solitary, transverse, many-flowered, on a flexuose, toothed receptacle. *Rees's Cyclopædia.*

Triticum hybernum. Willd. *Sp. Plant.* i. 477.—*T. vulgare*, var. β . *hybernum.* Kunth, *Gramin.*, 438. The common winter wheat has a fibrous root, and one or more erect, round, smooth, jointed stems, which rise from three to five feet in height, and are furnished with linear, pointed, entire, flat, many-ribbed, rough, somewhat glaucous leaves, and jagged bearded stipules. The flowers are in a solitary, terminal, dense, smooth spike, two or three inches long. The calyx is four-flowered, tumid, even, imbricated, abrupt, with a short compressed point. In the upper part of the spike it is more elongated; and in this situation the corolla is more or less awned. The grain is imbricated in four rows.

The native country of wheat is unknown; but its cultivation is supposed to have spread from Sicily over Europe. It is now an object of culture in almost all countries which enjoy a temperate climate. Sown in the autumn, it stands the winter, and ripens its seeds in the following summer. Numerous varieties have been produced by cultivation, some of which are usually described as distinct species. Among these may perhaps be ranked the *T. æstivum*, or spring wheat, distinguished by its long beards, and the *T. compositum*, or Egyptian wheat, by its compound spikes. It is asserted that the latter changes, in Great Britain, into the common single-spiked wheat. (*Loudon's Encyc.*) The seeds are too well known to need description. They are prepared for use by grinding and sifting, by which the interior farinaceous part is separated from the husk. The former is divided according to its fineness into different portions, but so far as regards its medical relations may be considered under one head, that of *farina* or *flour*. The latter is called *bran*, and constitutes from 25 to 33 per cent. according to the variety of wheat.

Flour is white, inodorous, and nearly insipid. Its chief constituents are starch, gluten, albumen, saccharine matter, and gum, the proportions of which are by no means constant. Vauquelin obtained, as an average pro-

duct, from eight varieties of flour which he examined, 10·25 per cent. of water, 10·80 of gluten (including coagulated albumen), 68·08 of starch, 5·61 of sugar, and 4·11 of gum. The ashes of wheat, which amount only to about 0·15 per cent., contain, according to Henry, superphosphates of soda, lime, and magnesia. The gummy substance found in wheat flour is not precisely identical with ordinary gum; as it contains nitrogen, and does not yield mucic acid by the action of nitric acid. The starch, which is by far the most abundant ingredient, is much employed in a separate state. (See *Amylum*.) The gluten, however, is not less important; as it is to the large proportion of this principle which wheat flour contains, that it owes its superiority over that of other grains for the preparation of bread. The *gluten* here alluded to is the substance first noticed as a distinct principle by Beccaria. It is the soft viscid fibrous mass which remains, when wheat flour, enclosed in a linen bag, is exposed to the action of a stream of water, and at the same time pressed with the fingers till the liquor comes away colourless. But this has been ascertained to consist, in fact, of two different substances. An Italian chemist, of the name of Taddei, found that by boiling it in alcohol a portion was dissolved, while another portion remained unaffected. Considering these as distinct principles, he gave the name of *gliadine* to the soluble, and *zymome* to the insoluble portion. But he had been anticipated in his experiments by the German chemist Einhof, who appears to have established the fact, that the part of the glutinous mass left behind by alcohol is identical with *vegetable albumen*, while the dissolved portion only is strictly entitled to the appellation of *gluten*, which had been previously conferred on the whole mass. As these two principles are contained in numerous vegetable products, and as they are frequently referred to in this work, it is proper that they should be briefly noticed. They both contain nitrogen, and both, when left to themselves in a moist state, undergo putrefaction. From these circumstances, and from their close resemblance to certain proximate animal principles in chemical habitudes and relations, they are sometimes called, in works on chemistry, *vegeto-animal substances*. They are separated from each other, as they exist in the mass originally denominated gluten, by boiling this mass with successive portions of alcohol, till the liquid, filtered while yet hot, ceases to become turbid on cooling. The gluten dissolves, and may be obtained by adding water to the solution, and distilling off the alcohol. Large cohering flakes float in the liquor, which, when removed, form a viscid elastic mass, consisting of the substance in question with some slight impurity. The part left behind by the alcohol is the albumen in a coagulated state.

Pure *gluten*, sometimes called *vegetable fibrin*, is a pale yellow, adhesive, elastic substance, which by drying becomes of a deeper yellow colour and translucent. It is almost insoluble in water, and quite insoluble in ether and in the oils both fixed and volatile. Hot alcohol dissolves it much more readily than cold; and from its solution in ordinary alcohol at the boiling temperature, it is precipitated unchanged when the liquor cools. It is soluble in the dilute acids, and in caustic alkaline solutions, in consequence of forming soluble compounds with the acids and alkalies. With the earths and metallic oxides it forms nearly insoluble compounds, which are precipitated when the earthy or metallic salts are added to the solution of gluten in liquid potassa. Corrosive sublimate precipitates it from its acid as well as alkaline solutions, and added in solution to moist gluten, forms with it a compound, which, when dry, is hard, opaque, and incorruptible. Gluten is also precipitated by infusion of galls. It bears a close resemblance to animal fibrin. Its name originated in its adhesive property. Gluten exists in most of the farinaceous grains, and in the seeds of some leguminous plants.

Vegetable albumen is destitute of adhesiveness, and when dried, is opaque, and of a white, gray, or brown colour. Before coagulation, it is soluble in water, but insoluble in alcohol. By heat it coagulates and becomes insoluble in water. It is dissolved by the solutions of the caustic alkalies. Most of the acids, if added to its solutions in excess, precipitate compounds of the acids respectively with the albumen, which, though soluble in pure water, are insoluble in that liquid when acidulated. It is not, however, precipitated by an excess of the phosphoric or acetic acid. Its relations with the earthy and metallic salts are similar to those of gluten. Corrosive sublimate precipitates it from its solutions, except from those in phosphoric and acetic acids, and when added in a state of solution to moist albumen, forms with it a hard, opaque compound. It is also precipitated by infusion of galls. This principle derived its name from its very close resemblance to animal albumen. It is associated with gluten in most of the farinaceous grains, is a constituent of all the seeds which form a milky emulsion with water, and exists in all the vegetable juices which coagulate by heat.

The mixture of gluten and albumen which constitutes the gluten of *Beccaria*, exercises an important influence over starch, which, with the presence of water and the aid of a moderate heat, it converts partly into gum and partly into sugar. The production of saccharine matter in the germination of seeds, and in the formation of malt, which is an example of germination, is thus accounted for. The gluten itself becomes acid in the process, and loses the property of reacting on starch.

It is now thought by many chemists that *vegetable albumen* is identical in all respects with *animal albumen*, and the *gluten* of vegetables with animal *fibrin*; and that both these principles, as well as another named *casein*, found also both in the animal and vegetable kingdoms, consist of a principle named *protein*, combined with a very small proportion of mineral substances, such as sulphur, phosphorus, &c. *Protein* consists of carbon, hydrogen, nitrogen, and oxygen; and its formula, according to Liebig, is $C_{43}H_{36}N_6O_{14}$. It is procured by dissolving any one of the substances above named in a strong solution of potassa, heating for some time to 120° , and precipitating with acetic acid. (*Turner's Chemistry*, 7th Lond. Ed.)

It is scarcely necessary to state, that bread is formed by making flour into a paste with water, with the addition of yeast, setting it aside to ferment, and then exposing it to the heat of an oven. The fermentation excited by the yeast is accompanied with the extrication of carbonic acid gas, which, being retained by the tenacity of the gluten, forms innumerable little cells through the mass, and thus renders the bread light. It is important to recollect that common salt is always added; as this ingredient is incompatible with some of the substances which are occasionally directed to be made into pills with the crumb of bread.

Medical Properties and Uses. Wheat flour in its unaltered state is seldom used in medicine. It is sometimes sprinkled on the skin in erysipelatous inflammation, and various itching or burning eruptions, particularly the nettle-rash; though rye flour is generally preferred for this purpose.

In the state of bread it is much more employed. An infusion of toasted bread in water is a pleasant, somewhat nutritive drink, very well adapted to febrile complaints. Within our experience, no drink has been found more grateful in such cases than this infusion, sweetened with a little molasses, and flavoured by lemon-juice. Boiled with milk, bread constitutes the common suppurative poultice, which may be improved by the addition of a small proportion of perfectly fresh lard. Slices of it steeped in lead-water, or the crumb mixed with the fluid and confined within a piece of gauze,

afford a convenient mode of applying this preparation to local inflammations. The crumb—*mica panis*—is, moreover, frequently used to give bulk to minute doses of very active medicines administered in the form of pill. It should be recollected, however, that it contains common salt, which is incompatible with certain substances, as, for example, the nitrate of silver.

Bran is sometimes used in decoction, as a demulcent in catarrhal affections and complaints of the bowels. It has, when taken in substance, laxative properties, and is used by some persons habitually and with great advantage to prevent costiveness. Bran bread, made from the unsifted flour, forms an excellent laxative article of diet in some dyspeptic cases. The action of the bran is probably altogether mechanical, consisting in the irritation produced upon the mucous membrane of the stomach and bowels by its coarse particles.

Gen. Ch. Receptacle naked. *Pappus* simple. *Calyx* scales equal, as long as the disk, submembranaceous. *Florets of the ray* ligulate or toothless. *Willd.*

Tussilago Farfara. *Willd. Sp. Plant.* iii. 1967; *Woodv. Med. Bot.* p. 45. t. 18. *Coltsfoot* is a perennial herb, with a creeping root, which early in the spring sends up several leafless, erect, simple, unifloral scapes or flower-stems, five or six inches high, and furnished with appressed scale-like bractes of a brownish-pink colour. The flower, which stands singly at the end of the scape, is large, yellow, compound, with hermaphrodite florets in the disk, and female florets in the ray. The latter are numerous, linear, and twice the length of the former. The leaves do not make their appearance until after the flowers have blown. They are radical, petiolate, large, cordate, angular and toothed at the margin, bright green upon their upper surface, white and downy beneath.

The plant grows spontaneously both in Europe and North America. In this country it is found upon the banks of streams in the Middle and Northern States, and flowers in April. The whole of it is directed by the London College, the leaves and flowers only by that of Dublin. The leaves are most frequently employed. They should be gathered after their full expansion, but before they have attained their greatest magnitude. (*London Dispensatory.*)

The flowers have an agreeable odour, which they retain after desiccation. The dried root and leaves are inodorous, but have a rough bitterish mucilaginous taste. Boiling water extracts all their virtues.

Medical Properties and Uses. *Coltsfoot* exercises little sensible influence upon the human system. It is, however, demulcent, and is sometimes used in chronic coughs, consumption, and other affections of the lungs. The expectorant properties which it was formerly thought to possess are not ob-

vious. The leaves were smoked by the ancients in pulmonary complaints; and in some parts of Germany they are at the present time said to be substituted for tobacco. Cullen states that he found the expressed juice of the fresh leaves, taken to the extent of some ounces every day, beneficial in several cases of scrofulous sores; and a decoction of the dried leaves, as recommended by Fuller, answered a similar purpose, though it often failed to effect a cure.

The usual form of administration is that of decoction. An ounce or two of the plant may be boiled in two pints of water to a pint, of which a tea-cupful may be given several times a day. W.

ULMUS. *Lond.*

Elm Bark.

“*Ulmus campestris. Cortex.*” *Lond.*

Off. Syn. ULMUS CAMPESTRIS. Cortex interior. *Dub.*

ULMUS. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Ulmaceæ.

Gen. Ch. Calyx five-cleft. Corolla none. Capsule (samara) compressed, membranaceous. *Willd.*

Ulmus campestris. Willd. *Sp. Plant.* i. 1324; Woodv. *Med. Bot.* p. 710. t. 242. This species of elm is characterized by its doubly serrate leaves, unequal at their base, by its nearly sessile, clustered, pentandrous flowers, and its smooth fruit. It is a large tree, with strong spreading branches, and a rough, cracked bark. It is a native of Europe, where the wood is highly esteemed for certain purposes in the arts.

The inner bark of its young branches, which is the officinal portion, is thin, tough, of a brownish-yellow colour, inodorous, and of a mucilaginous, bitterish, and very slightly astringent taste. It imparts to water its taste and mucilaginous properties. The tincture of iodine indicates the presence of starch, and Davy found somewhat more than two per cent. of tannin. A peculiar vegetable principle called *ulmin* or *ulmic acid*, now believed to be a constituent of most barks, was first discovered in the matter which spontaneously exudes from the bark of the European elm. It is a dark-brown almost black substance, without smell or taste, insoluble in cold water, sparingly soluble in boiling water which it colours yellowish-brown, soluble in alcohol, and readily dissolved by alkaline solutions.

Medical Properties and Uses. The bark of the European elm is demulcent, and very feebly tonic and astringent, and is said also to be diuretic. It has been recommended in cutaneous affections of the leprous and herpetic character; but is not at present very highly esteemed. It is usually given in the form of decoction, and must be long continued to produce beneficial results.

ULMUS. *U. S.*

Slippery Elm Bark.

“The inner bark of *Ulmus fulva.*” *U. S.*

ULMUS. See ULMUS. *Lond.*

Ulmus fulva. Michaux, *Flor. Americ.* i. 172.—*Ulmus rubra.* F. Andrew Michaux, *N. Am. Sylv.* iii. 89. The *slippery elm*, called also *red*

elm, is a lofty tree, rising fifty or sixty feet in height, with a stem fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are oblong ovate, acuminate, nearly equal at the base, unequally serrate, pubescent and very rough on both sides, four or five inches in length by two or three in breadth, and supported on short footstalks. The buds, a fortnight before their development, are covered with a dense russet down. The flowers which appear before the leaves, are sessile, and in clusters at the extremity of the young shoots. The bunches of flowers are surrounded by scales, which are downy like the buds. The calyx also is downy. There is no corolla. The stamens are five in number, short, and of a pale rose colour. The fruit is a membranaceous capsule or samara, enclosing in the middle one round seed, destitute of fringe.

This species of elm is indigenous, growing in all parts of the United States north of Carolina, but most abundantly west of the Alleghany mountains. It flourishes in open, elevated situations, and requires a firm, dry soil. From the white elm, *U. Americana*, it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark is the part used in medicine, and is brought to the shops separated from the epidermis.

It is in long, nearly flat pieces, from one to two lines in thickness, of a fibrous texture, a tawny colour which is reddish on the inner surface, a peculiar sweetish not unpleasant odour, and a highly mucilaginous taste when chewed. By grinding, it is reduced to a light, grayish-fawn coloured powder. It abounds in mucilaginous matter, which it readily imparts to water.

Medical Properties and Uses. Slippery elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in dysentery, diarrhoea, and diseases of the urinary passages. Like the bark of the common European elm, it has been employed in leprous and herpetic eruptions; but neither in these, nor in any other complaints, does it probably exert any greater powers than such as belong to the demulcents generally. Its mucilage is highly nutritious; and we are told that it has proved sufficient for the support of life in the absence of other food. The instance of a soldier is mentioned, who lived for ten days in the woods on this bark and sassafras; and the Indians are said to resort to it for nutriment in extreme emergencies.

It is usually employed as a drink in the form of infusion. (See *Infusum Ulmi*.) The powder may be used, stirred in hot water, with which it forms a mucilage, more or less thick according to the proportion added. The bark also serves as an emollient application, in cases of external inflammation. For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. Dr. McDowell, of Virginia, has recommended the use of slippery elm bark for the dilatation of fistulas and stricture. (*Med. Examiner*, i. 244, from the *West. Jour. of Med. and Phys. Sci.*)

VITIS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Vitaceæ.

Gen. Ch. Petals cohering at the apex, withering. Berry five-seeded, superior. Willd.

Vitis vinifera. Willd. *Sp. Plant.* i. 1180; Woodv. *Med. Bot.* p. 144. t. 57. The vine is too well known to require description. This particular species is distinguished by the character of its leaf, which is lobed, sinuated, and naked or downy. The leaves and tendrils are somewhat astringent, and were formerly used in diarrhœa, hemorrhages, and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the prejudice still lingers among the vulgar in some countries. The unripe fruit has a harsh sour taste, and yields by expression a very acid liquor, called *verjuice*, which was much esteemed by the ancients as a refreshing drink, when diluted with water. It contains malic and tartaric acids, and another called by some chemists *racemic acid*, by Berzelius *paratartaric acid*, from its resemblance to the tartaric, with which it agrees in composition, though differing from it in properties. The grape, when quite ripe, is among the most pleasant and grateful fruits brought upon the table, and is admirably adapted, by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter.

The plant is supposed to have been derived originally from Asia; but it has been cultivated in Europe and Northern Africa from the remotest antiquity, and is now spread over all the temperate civilized regions of the globe. The fruit is exceedingly influenced by soil and climate, and the varieties which have resulted from culture or situation are innumerable. Those which yield the raisins of commerce are confined to the basin of the Mediterranean.

Raisins are prepared either by partially cutting the stalks of the bunches before the grapes are perfectly ripe, and allowing them to dry upon the vine; or by picking them in their mature state, and steeping them for a short time previously to desiccation in an alkaline ley. Those cured by the first method are most highly esteemed.

Several varieties of raisins are known in commerce. The best of those brought to this country are the *Malaga* raisins, imported from Spain. They are large and fleshy, of a purplish-brown colour, and sweet agreeable taste. Those produced in Calabria are similar. The *Smyrna* raisins are also large, but of a yellowish-brown colour, slightly musky odour, and less agreeable flavour. They are originally brought from the coast of Syria. The *Corinthian raisins*, or *currants* as they are commonly called in this country, are small, bluish-black, of a fatty appearance, with a vinous odour, and a sweet slightly tartish taste. Their name was derived from the city in the vicinity of which they were formerly cultivated; at present they are

procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores*.

Raisins contain a larger proportion of sugar than recent grapes. This principle, indeed, is often so abundant that it effloresces on the surface, or concretes in separate masses within the substance of the raisin. The *sugar of grapes* differs slightly from that of the cane, and is said to be identical with that produced by the action of sulphuric acid upon starch. It is less sweet than common sugar, less soluble in cold water, much less soluble in alcohol, and forms a syrup of less consistence.

Medical Properties and Uses. The chief medical use of raisins is to flavour demulcent beverages. Taken in substance they are gently laxative; but are also flatulent and difficult of digestion, and when largely eaten sometimes produce unpleasant effects, especially in children.

ARBUTUS. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Ericaceæ.

Gen. Ch. *Calyx* five-parted. *Corolla* ovate, with a mouth, pellucid at the base. *Berry* five-celled. *Willd.*

Arbutus Uva Ursi. Willd. *Sp. Plant.* ii. 618; Bigelow, *Am. Med. Bot.* i. 66.—*Arctostaphylos Uva Ursi.* Sprengel, *Syst.* ii. 287.—The *uva ursi*, or *bearberry*, is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upwards for a few inches. The leaves are scattered, upon short petioles, obovate, acute at the base, entire, with a rounded margin, thick, coriaceous, smooth, shining, and of a deep green colour on their upper surface, paler and covered with a network of veins beneath. The flowers, which stand on short reflexed peduncles, are collected in small clusters at the ends of the branches. The calyx is small, five-parted, of a reddish colour, and persistent. The corolla is ovate or urceolate, reddish-white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the germ round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy, red berry, containing an insipid mealy pulp, and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes of Europe, Asia, and America. It is also found in the lofty mountains of Southern Europe, such as the Pyrennees and the Alps; and, on the American continent, extends from Hudson's Bay as far southward as New Jersey, in some parts of which it grows in great abundance. It prefers a barren soil, flourishing on gravelly hills, and elevated sandy plains. The leaves are the only

part used in medicine. They are imported from Europe; but are also collected within our own limits; and the market of Philadelphia is supplied to a considerable extent from New Jersey. They should be gathered in autumn, and the green leaves only selected.

In Europe the uva ursi is often adulterated with the leaves of the *Vaccinium Vitis Idæa*, which are wholly destitute of its peculiar properties, and may be distinguished by their rounder shape, their revolute edges which are sometimes slightly toothed, and the appearance of their under surface, which is dotted, instead of being reticulated as in the genuine leaves. Leaves of the *Chimaphila umbellata* may sometimes be found among the uva ursi as it exists in our markets. They may be readily detected by their greater length, their cuneiform lanceolate shape, and their serrate edges.

The leaves of the uva ursi are inodorous when fresh, but acquire a smell not unlike that of hay when dried and powdered. Their taste is bitterish, strongly astringent, and ultimately sweetish. They afford a light brown, greenish-yellow powder. Water extracts their active principles, which are also soluble in officinal alcohol. Among their ingredients are tannin, bitter extractive, resin, gum, and gallic acid; and the tannin is so abundant that they are used for tanning in some parts of Russia. Neither this principle nor gallic acid exists in the leaves of the *Vaccinium Vitis Idæa*.

Medical Properties and Uses. Uva ursi is astringent and tonic, and is thought by some to have a specific direction to the urinary organs, for the complaints of which it is chiefly used. Others deny that it possesses any peculiar tendency of this kind, and ascribe all its effects to its astringent and tonic action. It alters the colour of the urine, and its astringent principle has been detected in that secretion. It probably, therefore, exerts a direct influence on the kidneys and urinary passages. Though known to the ancients, it had passed into almost entire neglect, till its use was revived by De Haen about the middle of the last century. It has acquired some reputation as an antilithic, and has undoubtedly been serviceable in gravel, partly, perhaps, by a direct action on the kidneys, partly by giving tone to the digestive organs, and preventing the accumulation of principles calculated to produce a secretion or precipitation of calculous matter. In chronic nephritis it is also a popular remedy, and is particularly recommended when there is reason to conjecture the existence of ulceration in the kidneys, bladder, or urinary passages. Diabetes, catarrh of the bladder, incontinence of urine, gleet, leucorrhœa, and menorrhagia, are also among the diseases in which it has occasionally proved serviceable; and testimony is not wanting to its beneficial effects in phthisis pulmonalis. The dose of the powder is from a scruple to a drachm, to be repeated three or four times a day; but the form of decoction is usually preferred. (See *Decoctum Uvæ Ursi*.)

VALERIANA. *Sex. Syst.* Triandria Monogynia.—*Nat. Ord.* Valerianaceæ.

Gen. Ch. Calyx very small, finally enlarged into a feathery pappus. Corolla monopetalous, five-lobed, regular, gibbous at the base. Capsule one-celled. (*Loudon's Encyc. of Plants.*) Stamens exserted, one, two, three, and four. (*Nuttall.*)

Valeriana officinalis. Willd. *Sp. Plant.* i. 177; Woodv. *Med. Bot.* p. 77. t. 32. The *officinal*, or *great wild valerian* is a large handsome herbaceous plant, with a perennial root, and an erect, round, channelled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stem are attached by short broad sheaths, the radical leaves are larger and stand on long foot-stalks. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-coloured, odorous, and disposed in terminal corymbs, interspersed with spear-shaped pointed bractes. The number of stamens in this species is three. The fruit is a capsule containing one oblong ovate, compressed seed.

The plant is a native of Europe, where it grows either in damp woods and meadows, or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (*sylvestris*, L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves. It is superior to the others in medicinal virtue.

The root, which is the officinal portion, is collected in spring before the stem begins to shoot, or in the autumn when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous, long, slender, cylindrical fibres, issuing from a tuberculated head or rhizoma. As brought to this country it frequently has portions of the stem attached. The best comes from England.

Properties. The colour of the root is externally yellowish or brown, internally white. The powder is yellowish-gray. The odour, which in the fresh root is slight, in the dried is strong and highly characteristic, and though rather pleasant to many persons, is very disagreeable to others. Cats are said to be strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic. Valerian yields its active properties to water and alcohol. Trommsdorff found it to consist of 1·2 parts of volatile oil; 12·5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions; 18·75 of gum; 6·25 of a soft odorous resin; and 63 of lignin. Of these constituents the most important is the essential oil, in which the virtues of the root chiefly reside. It is of a pale greenish colour, of the sp. gr. 0·934, with a pungent odour of valerian, and an aromatic taste. It becomes yellow and viscid by exposure. Trommsdorff has ascertained that it contains a peculiar volatile acid, upon which the name of *valerianic acid* has been conferred. This, when separated from the oil, is a colourless liquid, of an oleaginous consistence, having an odour analogous to that of valerian, and a very strong, sour, disagreeable taste. It is soluble in thirty parts of water, and in all proportions in ether and alcohol. It combines with salifiable bases, forming soluble salts, which retain, in a diminished degree, the odour of the acid. (*Journ. de Pharm.* xx. 316.) Valerianic acid is obtained by distilling the impure oil from carbonate of magnesia, decomposing by sulphuric acid the valerianate of magnesia which remains, and again distilling.

The roots of the *Valeriana Phu* and *V. dioica* are said to be sometimes mingled with those of the officinal plant; but the adulteration is attended with no serious consequences; as, though much weaker than the genuine valerian, they possess similar properties. The same cannot be said of the roots of several of the *Ranunculaceæ*, which, according to Ebermayer, are sometimes fraudulently substituted in Germany. They may be readily detected by their want of the peculiar odour of the officinal root.

Medical Properties and Uses. Valerian is gently stimulant, with an especial direction to the nervous system, but without narcotic effect. In large doses it produces a sense of heaviness and dull pain in the head, with various other effects indicating nervous disturbance. It is useful in cases of irregular nervous action, when not connected with inflammation or an excited condition of the system. Among the complaints in which it has been particularly recommended, are hysteria, hypochondriasis, epilepsy, hemiplegia, and low forms of fever attended with restlessness, morbid vigilance, or other nervous disorder. It has also been used in intermittents combined with Peruvian bark. At best, however, it is an uncertain remedy. It may be given in powder or infusion. In the latter form, it is said by Professor Joerg of Leipsic, who has experimented with it, to be less apt to irritate the alimentary canal than when administered in substance. The dose of the powder is from thirty to ninety grains, repeated three or four times a day. The tincture is also officinal. As the virtues of valerian reside chiefly in the volatile oil, the medicine should not be given in decoction or extract. The distilled water is used on the continent of Europe; and the volatile oil is occasionally substituted with advantage for the root. The dose of the oil is four or five drops.

VERATRUM. Sex. Syst. Polygamia Monœcia.—*Nat. Ord.* Melanthaceæ.

Gen. Ch. HERMAPHRODITE. *Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* three. *Capsules* three, many-seeded. *MALE. Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* a rudiment. *Willd.*

Botanists who reject the class *Polygamia* of Linnæus, place this genus in the class and order *Hexandria Trigynia*, with the following character. “Polygamous. *Corolla* six-parted, spreading, segments sessile and without glands. *Stamens* inserted upon the receptacle. *Capsules* three, united, many-seeded.” *Nuttall.*

Veratrum album. Willd. Sp. Plant. iv. 895; *Woodv. Med. Bot.* p. 754. t. 257. This is an herbaceous plant, with a perennial, fleshy, fusiform root or rhizoma, yellowish-white externally, pale yellowish-gray within, and beset with long cylindrical fibres of a grayish colour, which constitute the true root. The stem is three or four feet high, thick, round, erect, and fur-

nished with alternate leaves, which are oval, acute, entire, plaited longitudinally, about ten inches long by five in breadth, of a yellowish-green colour, and embrace the stem at their base. The flowers are greenish, and arranged in a terminal panicle.

The white hellebore is a native of the mountainous regions of continental Europe, and abounds in the Alps and Pyrennees. All parts of the plant are said to be acrid and poisonous; but the root (rhizoma) only is officinal. This is brought to us from Germany in the dried state, in pieces from one to three inches long by an inch or less in mean diameter, cylindrical or in the shape of a truncated cone, internally whitish, externally blackish, wrinkled, and rough with the remains of the fibres which have been cut off near their origin. Sometimes the fibres continue attached to the root. They are numerous, yellowish, and of the size of a crow's quill. White hellebore deteriorates by keeping.

Properties. The fresh root has a disagreeable odour, which is lost by drying. The taste is at first sweetish, afterwards bitterish, acrid, burning, and durable. The powdered root is grayish. Analyzed by Pelletier and Caventou, white hellebore was found to contain an oily matter consisting of olein, stearin, and a volatile acid; supergallate of *veratria*, a yellow colouring matter, starch, gum, lignin, silica, and various salts of lime and potassa. The medicinal properties of the root reside in the *veratria*, which was first discovered in the seeds of the *Veratrum Sabadilla*, and probably exist in other plants belonging to the same family. For an account of *Veratria*, see *Sabadilla*, p. 610, and the article *Veratria*, among the Preparations. Simon believes that he has found two new vegetable alkalies in white hellebore, one of which is called *barytina*, from being precipitated, like baryta, from its solution in acetic or phosphoric acid by sulphuric acid or the sulphates; the other *jervina*, from the Spanish name for a poison obtained from the root of white hellebore. (*Pereira's Mat. Med.*, from *Pharm. Cent. Blatt.* 1837, s. 191.)

Medical Properties and Uses. White hellebore is a violent emetic and cathartic, capable of producing dangerous and fatal effects when incautiously administered. Even in small doses it has sometimes occasioned severe vomiting, hypercatharsis with bloody stools, and alarming symptoms of general prostration. Like many other acrid substances, it appears, in small doses, to be a general stimulant to the secretions. Applied externally upon a portion of the surface denuded of the cuticle, as upon ulcers for example, it gives rise to griping pain in the bowels, and sometimes violent purging. When snuffed up the nostrils, it occasions great irritation with violent sneezing, and its use in this way is not free from danger. It was employed by the ancients in dropsy, mania, epilepsy, leprosy, elephantiasis, and other obstinate disorders, not without occasional advantage; but the severity of its operation has led to its general abandonment as an internal remedy. It is sometimes used as an errhine, diluted with some mild powder, in cases of gutta serena and lethargic affections; and in the shape of decoction, or of ointment prepared by mixing the pulverized root with lard, has been found beneficial as an external application in the itch, and in other cutaneous eruptions. From the resemblance of its operation to that of the *eau medicinale d'Husson*, so celebrated for the cure of gout, it has been conjectured to be the chief constituent of that remedy—a reputation which has also been enjoyed by colchicum. A mixture of the wine of white hellebore and the wine of opium, in the proportion of three parts of the former to one of the latter, was introduced into use by Mr. Moor, of London, as a substitute for

the *eau medicinale*, and has been considerably employed in gouty and rheumatic affections.

In whatever way white hellebore is used, it requires cautious management. It has been given in doses varying from one grain to a scruple. Not more than two grains should be administered at first. When employed as an errhine it should be mixed with five or six parts of pulverized liquorice root or other inactive powder. Ten or twelve grains of the mixture may be snuffed up the nostrils at one time. *Veratria* acts in a similar manner with the white hellebore, but is much more powerful. From one-twelfth to one-sixth of a grain may be given in the form of pill or alcoholic solution, and repeated three or four times in the twenty-four hours, till it nauseates or purges. For an account of its practical applications, the reader is referred to *Veratria*, among the Preparations in the second part of this work.

VERATRUM VIRIDE. U.S.

American Hellebore.

“The rhizoma of *Veratrum viride*.” *U. S.*

VERATRUM. See VERATRUM ALBUM.

Veratrum viride. Willd. *Sp. Plant.* iv. 896; Bigelow, *Am. Med. Bot.* ii. 121. The American hellebore, known also by the names of *Indian poke*, *poke root*, and *swamp hellebore*, has a perennial, thick, fleshy root or rhizoma, the upper portion of which is tunicated, the lower solid and beset with numerous whitish fibres or radicles. The stem is annual, round, striated, pubescent, and solid, from three to six feet in height, furnished with green bright leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent; and embrace the stem at their base, thus affording it a sheath for a considerable portion of its length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong lanceolate. The panicle consists of numerous flowers distributed in racemes with downy peduncles. Each flower is accompanied with a downy pointed bracte much longer than its pedicel. There is no calyx, and the corolla is divided into six oval acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments, and roundish two-lobed anthers. The germs are three, with recurved styles as long as the stamens. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those on the lower portion fruitful. The fruit consists of three cohering capsules, separating at top, opening on the inner side, and containing flat imbricated seeds.

This indigenous species of *Veratrum* is found from Canada to Carolina, inhabiting swamps, wet meadows, and the banks of mountain streamlets. Early in the spring, before the stem rises, it bears a slight resemblance to the *Symplocarpus foetidus*, with which it is very frequently associated, but the latter sends forth no stem. From May to July is the season for flowering. The root should be collected in autumn, and should not be kept longer than one year, as it deteriorates by time.

The root of the American hellebore has a bitter acrid taste, leaving a permanent impression in the mouth and fauces. In sensible properties it bears

a close resemblance to white hellebore; and from this circumstance, as well as from the strong botanical affinity of the two plants, it is highly probable that it contains veratria. The experiments of Mr. Mitchell and Mr. Worthington, of Philadelphia, go to strengthen this probability. (See *Amer. Journ. of Pharm.* ix. 181. and x. 89.)

Medical Properties and Uses. American hellebore resembles its European congener in its effects upon the system, though asserted by Dr. Osgood to be wholly destitute of cathartic properties. In addition to its emetic action, which is often violent and long continued, it is said to increase most of the secretions, and, when freely taken, to exercise a powerful influence over the nervous system, indicated by faintness, somnolency, vertigo, headache, dimness of vision, and dilated pupils. According to Dr. Osgood, it reduces the frequency and force of the pulse, sometimes, when taken in full doses, as low as thirty-five strokes in the minute. It may be safely substituted for the European root in most cases in which the latter is employed; and is highly recommended as a substitute for colchicum by Dr. Tully of New Haven. Gouty, rheumatic, and neuralgic affections are those to which it appears best adapted. For an account of what may be said upon the medical properties and applications of the American hellebore, the reader is referred to a paper by Dr. Charles Osgood, of Providence, in the *American Journal of the Medical Sciences*, vol. xvi. p. 296. It may be used in substance, tincture, or extract. Dr. Osgood states the dose in which it will generally prove emetic at from four to six grains of the powder, one or two fluidrachms of a tincture made in the proportion of six ounces of the fresh root to a pint of alcohol, and one or two grains of an extract made by inspissating the juice of the root. The medicine, however, should, in most cases, be given in doses insufficient to vomit.

W.

VERBASCUM THAPSUS. Folia. *Dub.*

Mullein Leaves.

VERBASCUM. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Scrophulariaceæ.

Gen. Ch. Calyx five-parted. Corolla rotate, five-lobed, unequal. Stamens declined, bearded. Stigma simple. Capsule two-celled, valves inflexed, many-seeded. *Nuttall.*

Verbascum Thapsus. Willd. *Sp. Plant.* i. 1001; Woodv. *Med. Bot.* p. 202. t. 75. This is a biennial plant, with an erect, round, rigid, hairy stem, which rises from three to six feet in height, and is irregularly beset with large sessile, oblong or oval, somewhat pointed leaves, indented at the margin, woolly on both sides, and decurrent at the base. The flowers are yellow, and disposed in a long, close, cylindrical, terminal spike.

The mullein is common throughout the United States, growing along the road-sides and in neglected fields, and springing up abundantly in newly cleared places, at the most remote distance from cultivation. It is nevertheless considered by many botanists as a naturalized plant, introduced originally from Europe, where it is also abundant. It flowers from June to August. The leaves and flowers have been employed; but the former only are directed by the Dublin College. Both have a slight, somewhat narcotic smell, which in the dried flowers becomes agreeable. Their taste is mucilaginous, herbaceous, and bitterish, but very feeble. They impart their virtues to water by infusion.

Medical Properties and Uses. Mullein leaves are demulcent and emollient,

and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the Continent of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild catarrhs. Dr. Home found a decoction of the leaves useful in diarrhœa. The infusion or decoction may be prepared in the proportion of an ounce of the leaves to a pint of water, and given in the quantity of four fluidounces. The leaves are also employed externally, steeped in hot water, as a feebly anodyne emollient. An ointment is prepared from them in the recent state, and used for the same purposes. It may be made in the same manner as ointment of stramonium, by boiling the leaves in lard. It will be found advantageous to moisten them with water previously to the boiling. W.

VINUM. U. S.

Wine.

“Sherry wine.” U. S.

Off. Syn. VINUM XERICUM. *Lond.* VINUM ALBUM. *Sherry.* *Ed.*; VINUM ALBUM HISPANUM. *Dub.*

Vin, Fr.; Wein, Germ.; Vino, Ital., Span.

Wine is the fermented juice of the grape, the fruit of the *Vitis vinifera* of botanists, an important plant, the description of which will be found under another head. (See *Uva Passa*.) The juice of sweet grapes consists of a considerable quantity of grape sugar, a peculiar matter of the nature of ferment or yeast, and a small portion of extractive, tannic acid, bitartrate of potassa, tartrate of lime, common salt, and sulphate of potassa; the whole dissolved or suspended in a large quantity of water. Sour grapes contain, in addition, a peculiar acid isomeric with the tartaric, called *paratartaric acid*. Grape juice, therefore, embraces all the ingredients essential to the production of the vinous fermentation, and requires only the influence of the atmosphere and a proper temperature to convert it into wine. The theory of the vinous fermentation, and the agency of sugar in the process, have been explained under *Alcohol*.

Preparation. Though the art of making wine varies in different countries, yet it is regulated by general rules which require to be observed. When the grapes are ripe, they are gathered, and trodden under foot in wooden vessels with perforated bottoms, through which the juice, called the *must*, runs into a vat placed beneath. The temperature of the air being about 60°, the fermentation gradually takes place in the must, and becomes fully established after a longer or shorter period. In the mean time, the must becomes sensibly warmer, and emits a large quantity of carbonic acid, which, creating a kind of effervescence, causes the more solid parts to be thrown to the surface in a mass of froth having a hemispherical shape called the *head*. The liquor, from being sweet, becomes vinous, and assumes a deep red colour if the product of red grapes. After a while the fermentation slackens, when it becomes necessary to accelerate it by thoroughly mixing the contents of the vat. When the liquor has acquired a strong vinous taste, and become perfectly clear, the wine is considered formed, and is racked off into casks. But even at this stage of the process, the fermentation is not completed, but continues for several months longer. During the whole of this period, a frothy matter is formed, which, for the first few days, collects round the bung, but afterwards precipitates along with colouring matter and tartar, forming a deposit which constitutes the wine-lees.

Division and Nomenclature. Wines, according to their colour, are

divided into the red and white; and, according to their taste and other qualities, are either spirituous, sweet, dry, light, sparkling, still, rough, or acidulous. *Red wines* are derived from the must of black grapes, fermented with their husks; *white wines*, from white grapes, or from the juice of black grapes fermented apart from their skins. The other qualities of wines above enumerated, depend on the relative proportions of the constituents of the must, and on the mode in which the fermentation is conducted. The essential ingredients of the must as a fermentable liquid, are water, sugar, and a ferment. If the juice be very saccharine, and contain sufficient ferment to sustain the fermentation, the conversion of the sugar into alcohol will proceed until checked by the production of a certain amount of the latter, and there will be formed a *spirituous* or *generous* wine. If, while the juice is highly saccharine, the ferment be deficient in quantity, the production of alcohol will be less and the redundancy of sugar proportionably greater, and a *sweet wine* will be formed. When the sugar and ferment are in considerable amount, and in the proper relative proportions for mutual decomposition, the wine will be strong-bodied and sound, without any sweetness or acidity, and of the kind called *dry*. A small portion of sugar can give rise only to a small portion of alcohol, and consequently the less saccharine grapes will generate a comparatively weak, or *light wine*, which will be sound and stable in its constitution, in case the ferment is not in excess, but otherwise liable to pass into the acetous fermentation and become acescent. In case the wine is bottled before the fermentation is fully completed, the process will continue slowly in the bottles, and the carbonic acid generated, not having vent, will impregnate the wine, and render it effervescing and *sparkling*. The *rough* or astringent wines owe their flavour to a portion of tannic acid derived from the husks of the grape; and the *acidulous* wines, to the presence of carbonic acid or an unusual proportion of tartar. Several of the above qualities often co-exist. Thus a wine may be spirituous and sweet, spirituous and rough, rough and sweet, light and sparkling, &c.

Wines are made in many countries, and are known in commerce by various names according to their source. Thus, *Portugal* produces port and lisbon; *Spain*, sherry, saint lucar, malaga, and tent; *France*, champagne, burgundy, hermitage, vin de Grave, sauterne, and claret; *Germany*, hock and moselle; *Hungary*, tokay; *Sicily*, marsala or Sicily madeira, and lissa; the *Cape of Good Hope*, constantia; *Madeira and the Canaries*, madeira and teneriffe. In the United States, a small portion of wine is made, for the most part of inferior quality. The best is manufactured near Vevay, a Swiss settlement on the banks of the Ohio. The consumption of this country is accordingly supplied almost entirely from abroad; and the wines most extensively imported are madeira, teneriffe, sherry and port, and the claret wines of France.

Properties. Wine, considered as the name of a class, may be characterized as a spirituous liquid, the result of the fermentation of grape-juice, and containing colouring matter, and some other substances, which are either combined or intimately blended with the spirit. All its other qualities vary with the nature of each particular wine. It will not be necessary to describe all the wines that have been enumerated; but only such as are commonly used for medicinal purposes. Under this denomination may be included the officinal wine sherry, together with madeira, teneriffe, port, and claret.

Sherry is of a deep amber colour, and when good possesses a dry aromatic flavour and fragrancy, without any acidity. It ranks among the stronger white wines, and contains between 19 and 20 per cent. by measure

of alcohol of sp. gr. 0·825. The United States and British Pharmacopœias now agree in indicating it as the officinal wine. It is prepared in the vicinity of Xeres in Spain, and hence its English name *sherry*. This wine is supposed to have been the *sack* of Shakspeare, so called from the word *sec* (dry), in allusion to its being a dry wine. Its dryness or freedom from acidity is said to arise from the use of lime in its manufacture.

Madeira is the strongest of the white wines in general use. It is a slightly acid wine, and, when of proper age and in good condition, has a nutty, rich, aromatic flavour. As it occurs in the market, however, it is of very variable quality, on account both of the less care taken in its manufacture than formerly, and of the adulterations and mixtures to which it is subjected after importation. The madeira consumed in this country is generally much better than that used in England, its adulteration being practised to a less extent with us, and our climate being more favourable to the improvement of the wine.

Teneriffe is a white wine, of a slightly acid taste, and, when of good quality, of a fine aromatic flavour. Its average strength is about the same as that of sherry. It is made from the same grape as madeira, to which it bears a close resemblance.

Port is of a deep purple colour, and, in its new state, is a rough, strong, and slightly sweet wine. When kept a certain length of time in bottles, it deposits a considerable portion of its astringent matter, loses the greater part of its sweetness, acquires more flavour, and retains its strength. If too long kept, it deposits the whole of its astringent and colouring matter, and becomes deteriorated. Considerable quantities of brandy are usually added to it, which causes its heating quality on the palate. It is the strongest of all the wines in common use.

Claret, called in France, *vin de Bordeaux*, is also a red wine, and from its moderate strength is ranked as a light wine. It has a deep purple colour, and when good a delicate taste, in which the vinous flavour is blended with slight acidity and astringency. The most esteemed kinds are the Medoc clarets, called *Château-Lafite*, *Château-Margaux*, and *Château-Latour*. Another celebrated variety is the *Château-Haut Brion* of the Pays de Grave. Claret is the only French wine extensively consumed in the United States. It is made in large quantities in the country around Bordeaux, from which port it is shipped.

Adulterations. Wines are very frequently adulterated, and counterfeit mixtures are often palmed upon the public as genuine wine. Formerly the wine dealers were in the habit of putting litharge into wines that had become acescent. The oxide of lead formed with the acetic acid acetate of lead, which, being sweet, corrected the defect of the wine, but at the same time rendered it poisonous. At the present day, however, this criminal practice is wholly abandoned. The adulteration is readily detected by sulphuretted hydrogen, which causes a black and flocculent precipitate. Mr. Brande assures us, that among the numerous samples of wine of suspected purity which he had examined, he had not found one containing any poisonous ingredient fraudulently introduced. Lead, in minute quantity, according to this writer, may often be detected in wines; but it is derived invariably from shot in the bottle, or some analogous source. Spurious mixtures, frequently containing very little of the fermented juice of the grape, which are sold for particular wines, may not be poisonous; but are notwithstanding highly pernicious in their effects upon the stomach, and always produce mischief and disappointment, when depended on as therapeutic agents. The wines most frequently imitated are port and madeira; and cider is gene-

rally the chief ingredient in the spurious mixtures. *English port* is sometimes made of a small portion of real port mixed with cider, juice of elder berries, and brandy, coloured and rendered astringent with logwood and alum. In the United States, of latter years, the cheapness of genuine wines has left little motive for manufacturing these factitious imitations.

Composition. Wines consist mainly of water and alcohol. They contain, besides, sugar, gum, extractive, colouring matter, tannic, malic, and carbonic acids, bitartrate of potassa (tartar), tartrate of lime, volatile oil, and ænanthic ether. The volatile oil has never been isolated, but is supposed to be the cause of the delicate flavour and odour of wine, called the *bouquet*. *Ænanthic ether* (ænanthate of ether, ænanthate of oxide of ethule), was discovered by Pelouze and Liebig. It is obtained towards the end of the distillation of wine on the great scale for making brandy. It forms only about one-ten thousandth part of the wine. It is a mobile, oily, colourless liquid, having the peculiar unpleasant smell which is perceived in a bottle which has contained wine. Its sp. gr. is 0.862, and boiling point 435° . Its formula is $C_{18}H_{18}O_3 = C_{14}H_{13}O_2$ (ænanthic acid) + C_4H_5O (ether). Ænanthic ether must not be confounded with the volatile oil upon which the bouquet of wine is supposed to depend. The other ingredients of wine, above enumerated, are not to be supposed present in every wine. Thus sugar is present in sweet wines, tannic acid in rough wines, and carbonic acid in those that effervesce. Malic acid exists in minute proportion in some wines, and is absent in others. The different kinds of wine derive their various qualities from the mode of fermentation, the nature of the grape, and the soil and climate in which it may have grown. The alcohol in pure wine is that which results from the vinous fermentation, and is intimately united with the other ingredients of the liquor; but with almost all the wines of commerce a portion of brandy is mixed, the state of union of which is probably different from that of the natural alcohol of the wine. By the custom-house regulations in England, ten per cent. of brandy may be added to wines after importation; but to good wines not more than four or five per cent. is added.

The intoxicating ingredient in all wines is the alcohol which they contain; and hence their relative strength depends upon the quantity of this substance entering into their composition. The alcohol, however, naturally in wine, is so blended with its other constituents, as to be in a modified state, which renders it less intoxicating and less injurious than the same quantity of alcohol separated by distillation and diluted with water. Mr. Brande published in 1811 a very interesting table, giving the percentage by measure of alcohol of sp. gr. 0.825 in different kinds of wine. Similar tables have since been published by M. Julia-Fontenelle, and Dr. Christison. An abstract of their results is given in the following table, the proof spirit of Dr. Christison's table (0.920) being reduced, for the sake of comparison, to the standard of 0.825, the density of the spirit, adopted by Mr. Brande. The results of Julia-Fontenelle are distinguished by the letter J.; those of Dr. Christison by the letter C. The rest are Mr. Brande's.

Table of the Proportion by Measure of Alcohol (sp. gr. 0.825) contained in 100 parts of different Wines.

Lissa, (mean)	-	-	25.41	Port, mean	-	-	22.96

White hermitage	-	-	17.43	Hambacher, first quality, (C.)	-	-	8.88

By the above table it is perceived that, with one or two exceptions, Dr. Christison found less alcohol in wines than Mr. Brande. Dr. Christison considers it a mistake to suppose that wines become stronger by being kept a long time in cask. His experiments appear to prove the reverse. While, however, the wine is not rendered more alcoholic by age, its flavour is improved, and its body or apparent strength is increased.

Besides the grape, a number of other fruits yield a juice susceptible of the vinous fermentation. The infusion of malt, also, is capable of undergoing this process, and becomes converted into the different kinds of porter and ale. The product in all these cases, though not commonly called a wine, is nevertheless a vinous liquor, and may be classed among the wines properly so called. The following is a list of these vinous liquors, together with the percentage of alcohol which they contain, as ascertained by Mr. Brande:—Currant wine, 20.55; gooseberry wine, 11.84; orange wine, 11.26; elder wine, 8.79; cider, from 5.21 to 9.87; perry, 7.26; mead, 7.32; Burton ale, 8.88; Edinburgh ale, 6.20; brown stout, 6.80; London porter, 4.20; small beer, 1.28.

Medical Properties and Uses. Wine is consumed in most civilized countries; but in a state of health it is at least useless, if not absolutely pernicious.

The degree of mischief which it produces, depends very much on the character of the wine. Thus the light wines of France are comparatively innocuous; while the habitual use of the stronger ones, such as port, madeira, sherry, &c., even though taken in moderation, is always injurious, as having a tendency to induce gout and apoplexy, and other diseases dependent on plethora and over-stimulation. All wines, however, when used habitually in excess, are productive of bad consequences. They weaken the stomach, produce disease of the liver, and give rise to dropsy, gout, apoplexy, tremors, and not unfrequently mania. Nevertheless, wine is an important medicine, productive of the best effects in certain diseases and states of the system. As an article of the *materia medica*, it ranks as a stimulant and antispasmodic. In the convalescence from protracted fever, and in sinking of the vital powers, it is frequently the best remedy that can be employed. In certain stages of typhoid fevers, and in extensive ulceration and gangrene, this remedy, either alone, or conjoined with bark or opium, is often our main dependence. In low febrile affections, if it increase the fulness and lessen the frequency of the pulse, mitigate delirium, and produce a tendency to sleep, its further use may be deemed proper; but, on the contrary, if it render the pulse quicker, augment the heat and thirst, produce restlessness, or increase delirium, it should be immediately laid aside as injurious. In some convulsive diseases, as for example tetanus, wine, liberally given, has been found useful.

Wine, when used medicinally, should be sound, and good of its kind; for otherwise it will disagree with the stomach, and prove rather detrimental than useful. The individual wine selected for internal exhibition must be determined by the nature of the disease, and the particular object in view. *Sherry*, when in good condition, is a fine wine, and, being free from all acid, is to be preferred whenever the stomach is delicate, or has a tendency to dyspeptic acidity. Unfortunately, however, it is of very unequal quality. Good *madeira* is the most generous of the white wines, particularly adapted to the purpose of resuscitating debilitated constitutions, and of sustaining the sinking energies of the system in old age. The slight acidity, however, of pure madeira causes it to disagree with some stomachs, and renders it an improper wine for gouty persons. *Teneriffe* is a good variety of white wine for medicinal use, being of about a medium strength, and agreeing very well with most stomachs. *Port* is generally used in cases of pure debility, especially when attended with a loose state of the bowels unaccompanied by inflammation. In such cases, it often acts as a powerful tonic as well as stimulant, giving increased activity to all the functions, especially digestion. *Claret* is much less heating, and is often useful on account of its aperient and diuretic qualities.

All the acid and acidulous wines are contra-indicated in the gouty and uric acid diathesis, as they are very apt to convert the existing predisposition into disease. They are useful, however, in what is called the phosphatic diathesis, their acidity tending to prevent the deposition of the earthy phosphates.

The quantity of wine which may be given with advantage in disease, is necessarily very variable. In low fevers, it may be administered to the extent of a bottle or more in twenty-four hours, either pure, or in the form of *wine-why*. This is made by adding from a gill to half a pint of wine to a pint of boiling milk, straining without pressure to separate the curd which is formed, and sweetening the clear whey with loaf sugar. Wine-why forms a peculiarly safe and grateful stimulus in typhoid fevers and other febrile affections, which, after depletion, may tend to a state of deficient

action and be accompanied with a dry skin. Under these circumstances, it often acts as a diaphoretic, and, if used of moderate strength, without stimulating the system in any marked degree.

Pharmaceutical Uses. Wine is employed as a menstruum to extract the virtues of several plants, and the preparations thus formed are called *vinous tinctures* or *medicated wines*. Tartar emetic is the only mineral substance prepared in a similar manner. (See *Vinum Antimonii*.) For the peculiar powers of wine as a menstruum for medicinal substances, see *Vina Medicata*. B.

VIOLA. U.S. Secondary.

Violet.

“The herb of *Viola pedata*.” U.S.

VIOLA ODORATA. Flores. Dub.

Flowers of the Sweet Violet.

Off. Syn. VIOLA. Flowers of *Viola odorata*. *Ed.*

Violette odorante, Fr.; Wohlriechendes Veilchen, Germ.; Violetta, Ital.; Violeta, Span.

VIOLA. Sex. Syst. Pentandria Monogynia.—*Nat. Ord.* Violaceæ.

Gen. Ch. *Calyx* five-leaved. *Corolla* five-petaled, irregular, horned at the back. *Anthers* cohering. *Capsule* superior, three-valved, one-celled.

This genus includes numerous species, of which, though perhaps all or nearly all are possessed of analogous properties, two only are recognised as officinal, the *V. odorata*, by the Edinburgh and Dublin Colleges, and the *V. pedata*, by our National Pharmacopœia. The *V. ovata*, an indigenous species, has been recommended as a remedy for the bite of the rattlesnake. (See a paper by Dr. Williams in the *Am. Journ. of the Med. Scien.* xiii. 310.)

Viola odorata. Willd. *Sp. Plant.* i. 1163; Woodv. *Med. Bot.* p. 251. t. 89. This is a small, pretty, creeping plant, the runners of which are furnished with fibrous roots, and send up annually tufts of leaves and flowers. The leaves are heart-shaped, crenate, and supported on long petioles. The flowers are at the summit of delicate, quadrangular, channeled, radical peduncles. The leaves of the calyx are shorter than the petals, which are obovate, obtuse, unequal, and of a bluish-purple or deep violet colour, except at the claws which are whitish. The two lateral petals are spreading and bearded towards the base, the inferior furnished with a large spur, and the two upper reflected. In the centre are the stamens with very short filaments, and anthers slightly cohering by an orange-coloured membranous expansion.

The sweet violet is a native of Europe, growing in woods, hedges, and other shady places. It is cultivated in gardens both for its beauty and for medical use; and has been introduced into this country. It is valued chiefly for its flowers, which appear in April and May.

The flowers of this species of violet, besides their beautiful colour, have a peculiar agreeable odour, and a very slightly bitter taste. These properties they yield to boiling water; and their infusion affords a very delicate test for acids and alkalies, being reddened by the former, and rendered green by the latter. Their odour is destroyed by desiccation; and the degree to which they retain their fine colour, depends upon the care used in collect-

ing and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room, or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same colour, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of the *V. odorata*, M. Boulay has discovered a peculiar alkaline principle, bearing some resemblance to *emetia*, but possessing distinct properties. He calls it *violine*; but *violia* is its proper title in accordance with the nomenclature adopted in this work. It is white, soluble in alcohol, scarcely soluble in water, and forms salts with the acids. It exists in the plant combined with malic acid, and may be obtained by treating with distilled water the alcoholic extract of the dried root, decomposing by means of magnesia the malate of *violia* contained in the solution, and extracting the alkali from the precipitated matters by alcohol, which yields it on evaporation. To obtain it entirely pure, a more complicated process is necessary. Orfila has ascertained that it is exceedingly active and even poisonous. It is probably contained in most of the other species of *Viola*.

Viola pedata. Willd. *Sp. Plant.* i. 1160. Curtis, *Bot. Mag.* 89. This is an indigenous species, without stems, glabrous, with many-parted often pedate leaves, the segments of which are linear lanceolate, obtuse, and nearly entire. The flowers are large and of a beautiful blue colour, often more or less variegated. The divisions of the calyx are linear and acute. The stigma is large, compressed at the sides, obliquely truncate and perforate at the apex. The plant grows in dry sandy hills and fields, and rocky woods, from New England to Carolina, and flowers in May and June.

Medical Properties, &c. of the Violets. The herbaceous parts of different species of violet are mucilaginous, emollient, and slightly laxative; and have been used in pectoral, nephritic, and cutaneous affections. Much was formerly thought of the *Viola tricolor* or pansy, as a remedy in the crusta lactea. A decoction in milk of a handful of the fresh, or half a drachm of the dried herb was taken morning and evening, and a poultice made with the same decoction was applied to the affected part. Cures in numerous instances are said to have been effected by this treatment persevered in for some time. Our own *Viola pedata* is considered a useful expectorant and demulcent in pectoral complaints. (*Bigelow.*)

In Europe, a syrup prepared from the fresh flowers of the *Viola odorata* is much employed as an addition to demulcent drinks, and as a laxative for infants. (See *Syrupus Violæ*.) The seeds were formerly considered useful in gravel, but are not now employed. The root, which has a bitter, nauseous, slightly acrid taste, acts in the dose of thirty grains or a drachm as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of *Ionidium*, which belong to the same natural family. The existence in small proportion of the emetic principle, upon which the powers of the root probably depend, in the leaves and flowers, accounts for the expectorant properties long attributed to these parts of the plant.

WINTERA. U.S. Secondary.

Winter's Bark.

"The bark of *Wintera aromatica*—*Drymis Wintera* (*De Candolle*)."
U. S.

Off. Syn. WINTERA AROMATICA. DRYMIS AROMATICA.
Cortex. Dub.

Ecorce de Winter, Fr.; Wintersche Rinde, Germ.; Corteccia Vinterana, Ital.; Corteza Winterana, Span.

DRYMIS. Sex. Syst. Polyandria Tetragynia.—*Nat. Ord.* Magnoliaceæ,
Juss.; Winteraceæ, Lindley.

Gen. Ch. *Calyx* with two or three deep divisions. *Corolla* with two or three petals, sometimes more numerous. *Stamens* with the filaments thickened at the summit, and anthers having two separate cells. *Ovaries* from four to eight, changing into the same number of small, many-seeded berries.
A. Richard.

Drymis Winteri. De Cand. *Prod.* ii. 78; Foster, *Gen.* p. 84. t. 42.—*Wintera aromatica.* Willd. *Sp. Plant.* ii. 1239; Woodv. *Med. Bot.* p. 647. t. 226. This is an evergreen tree, varying very much in size, sometimes rising forty or fifty feet in height, sometimes not more than six or eight feet. The bark of the trunk is gray, that of the branches green and smooth. Its leaves are alternate, petiolate, oblong, obtuse, somewhat coriaceous, entirely smooth, green on their upper surface, of a pale bluish colour beneath, with two caducous stipules at their base. The flowers are small, sometimes solitary, but more frequently in clusters of three or four, upon the summit of a common peduncle about an inch in length, simple, or divided into as many pedicels as there are flowers. The tree is a native of the southern part of South America, growing along the Straits of Magellan, and extending as far north as Chili. According to Martius it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake in his voyage round the world, and while in the Straits had learned its aromatic and medicinal properties. Since that period it has been occasionally employed in medicine.

It is in quilled pieces, usually a foot in length, and an inch or more in diameter, appearing as if scraped or rubbed on the outside, where the colour is pale yellowish or reddish-gray, with red elliptical spots. On the inside the colour is that of cinnamon, though sometimes blackish. The pieces are sometimes flat and very large. The bark is two or three lines in thickness, hard and compact, and when broken exhibits on the exterior part of the fracture a grayish colour, which insensibly passes into reddish or yellowish towards the interior. The powder resembles in colour that of Peruvian bark. The odour is aromatic, the taste spicy, pungent, and even burning.

Winter's bark was found by M. Henry to contain resin, volatile oil, colouring matter, tannic acid, several salts of potassa, malate of lime, and oxide of iron. The presence of tannic acid and oxide of iron serves to distinguish it essentially from the *canella alba*, with which it is often confounded.

Medical Properties and Uses. It is a stimulant aromatic tonic, and was employed by Winter as a remedy for scurvy. It may be used for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. The dose of the powder is about half a drachm.

XANTHORRHIZA. U.S. Secondary.*Yellow-root.*

“The root of *Xanthorrhiza apiifolia*.” *U. S.*

XANTHORRHIZA. Sex. Syst. Pentandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx none. Petals five. Nectaries five, pedicelled. Capsules five to eight, one-seeded, semibivalve. *Nuttall.*

Xanthorrhiza apiifolia. Willd. *Sp. Plant.* i. 1568; Barton, *Med. Bot.* ii. 203.—*X. tinctoria.* Woodhouse, *N. Y. Med. Repos.* vol. v. This is an indigenous shrub, two or three feet in height, with a horizontal root, which sends off numerous suckers. The stem is simple, rather thicker than a goose-quill, with a smooth bark, and bright yellow wood. The leaves, which stand thickly at the upper part of the stem, are compound, consisting of several ovate lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. The nectaries are obovate and bilobed, the styles usually about six or eight in number.

The yellow-root grows in the interior of the Southern and in the Western States. Nuttall says that it is abundant on the banks of the Ohio. It flowers in April. The root is the part directed by the Pharmacopœia; but the bark of the stem possesses the same virtues.

The root is from three inches to a foot in length, about half an inch in thickness, of a yellow colour, and of a simple but extremely bitter taste. It imparts its colour and taste to water. The infusion is not affected by a solution of the sulphate of iron. By the late Professor Barton the bark of the root was considered more bitter than its ligneous portion.

Medical Properties and Uses. *Xanthorrhiza* possesses properties closely analogous to those of columbo, quassia, and the other simple tonic bitters; and may be used for the same purposes, and in the same manner. Dr. Woodhouse employed it in the dose of two scruples, and found it to lie easily upon the stomach.

W.

XANTHOXYLUM. U.S. Secondary.*Prickly Ash.*

“The bark of *Xanthoxylum fraxineum*.” *U. S.*

XANTHOXYLUM. Sex. Syst. Diœcia Pentandria.—*Nat. Ord.* Terebin-taceæ, *Juss.*; Xanthoxylaceæ, *Lindley.*

Gen. Ch. MALE. Calyx five-parted. Corolla none. FEMALE. Calyx five-parted. Corolla none. Pistils five. Capsules five, one-seeded. *Willd.*

Xanthoxylum fraxineum. Willd. *Sp. Plant.* iv. 757; Bigelow, *Am. Med. Bot.* iii. 156. The prickly ash is a shrub from five to ten feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface. The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polyga-

mous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. Each fruitful flower is followed by as many capsules as it had germs. These capsules are stipitate, oval, punctate, of a greenish-red colour, with two valves, and one oval blackish seed.

This species of *Xanthoxylum* is indigenous, growing in woods and in moist shady places, throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odour recalling that of the oil of lemons. The bark is the officinal portion.

This, as found in the shops, is in pieces more or less quilled, from one to two lines in thickness, of a whitish colour, internally somewhat shining, with an ash-coloured epidermis, which in some specimens is partially or wholly removed, and in those derived from the small branches is armed with strong prickles. The bark is very light, brittle, of a farinaceous fracture, nearly or quite inodorous, and of a taste which is at first sweetish and slightly aromatic, then bitterish, and ultimately acrid. The acrimony is imparted to boiling water and alcohol, which extract the virtues of the bark. Its constituents, according to Dr. Staples, besides fibrous substance, are volatile oil, a greenish fixed oil, resin, gum, colouring matter, and a peculiar crystallizable principle which he calls *xanthoxylin*, but of which the properties are not designated. (*Journ. of the Phil. Col. of Pharm.* i. 165.)

Dr. Bigelow states that the *Aralia spinosa*, or angelica tree, which grows in the Southern States, is occasionally confounded with the *X. fraxineum*, in consequence, partly, of being sometimes called like the latter *prickly ash*. Its bark, however, in appearance and flavour, is entirely different from the *xanthoxylum*.

Medical Properties and Uses. *Xanthoxylum* is stimulant, producing when swallowed a sense of heat in the stomach, with more or less general arterial excitement, and a tendency to diaphoresis. It is thought to resemble mezereon and guaiac in its remedial action, and is given in the same complaints. As a remedy in chronic rheumatism, it enjoys considerable reputation in this country. The dose of the powder is from ten grains to half a drachm, to be repeated three or four times a day. A decoction prepared by boiling an ounce in three pints of water down to a quart, may be given in the quantity of a pint, in divided doses, during the twenty-four hours.

The powder has sometimes been employed as a topical irritant, and the bark is a popular remedy for toothache. W.

ZINCUM. U.S., Lond., Ed., Dub.

Zinc.

Speltre; Zinc, *Fr.*; Zink, *Germ.*; Zinco, *Ital.*, *Span.*

Zinc occurs native in two principal states; as a sulphuret, called *blende*, and as a carbonate or silicate, denominated *calamine*. It is found in various parts of the world, but most abundantly in Germany, from which country the United States are principally supplied. The metal is extracted generally from calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders placed horizontally over a furnace. When the reduction of the zinc commences, iron receivers are adapted to the

opening of the cylinder to receive the volatilized metal as it condenses. The metal is then melted and run into moulds, and forms *speltre*, or the zinc of commerce. In this state it is not pure, but contains iron, and traces of lead, cadmium, arsenic, copper, sulphur, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom and open at both ends; its upper extremity reaching a little more than half way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and passing down the tube by a descending distillation, condenses in the water below.

Properties. Zinc has a bluish-white colour, a peculiar taste and a perceptible smell when rubbed. Its texture is laminated and its fracture crystalline. Its malleability and ductility are not very great. When perfectly pure, it may be reduced to thin leaves at ordinary temperatures; but the zinc of commerce requires to be heated to a temperature between 212° and 300° to render it laminable, when it may be conveniently reduced to the form of sheets. The softness of zinc is peculiar, as is shown by the circumstance that it clogs the file when the attempt is made to reduce it to filings; and hence, if it be desired to have it in the divided form, it is necessary to submit it to fusion, and to triturate it at the moment of solidification. Its sp. gr. is about 7.1, its equivalent number 32.3, and symbol Zn. Subjected to heat, it fuses at 773° . At full redness it boils, and in close vessels may be distilled over; but in open ones it takes fire, and burns with a dazzling white flame, giving off dense white fumes. It dissolves in most of the acids with disengagement of hydrogen, and precipitates all the metals either in the metallic state or in that of oxide. It forms but one well characterized oxide (a protoxide), and but one sulphuret. A peroxide was obtained by Thenard, but its properties and composition are unknown. The protoxide is officinal, and will be described under another head. (See *Zinci Oxidum*.)

Zinc of good quality dissolves in dilute sulphuric acid, with the exception of a scanty grayish-black residuum. If absolutely pure it would be wholly dissolved. The solution is colourless, and yields white precipitates with ferrocyanuret of potassium and hydrosulphate of ammonia. Ammonia throws down from this solution a white precipitate, which is wholly dissolved when the alkali is added in excess. If copper be present the solution will be rendered blue by the ammonia; and if iron be an impurity it will be thrown down by this alkali, but not redissolved by its excess.

Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction with copper, for galvanic combinations. Combined with tin and mercury, it forms the amalgam for electrical machines. Its solution in dilute sulphuric acid furnishes the readiest method for obtaining hydrogen. With copper it forms the useful alloy called *brass*, and in the form of *sheet zinc* it is employed to cover the roofs of houses. It should never be used for culinary vessels, as it is soluble in the weakest acids.

Pharmaceutical Uses. Zinc is never used in medicine in the metallic state; but is employed in this state to form the officinal preparations, acetate, sulphate, and chloride of zinc. In combination, it forms a number of important preparations, a list of which, with the synonymes, is subjoined.

Zinc is employed medicinally,—

B.

ZINCI CARBONAS. *U. S.**Carbonate of Zinc.*“Native impure carbonate of zinc.” *U. S.**Off. Syn.* CALAMINA. *Lond.*; ZINCI CARBONAS IMPURUM. CALAMINA. *Dub.*Calamine; Lapis calaminaris, *Lat.*; Carbonate de zinc, Calamine, *Fr.*; Galmei, *Germ.*; Giallamina, Pietra calaminaria, *Ital.*; Calamina, *Span.*

The term *calamine* is applied by mineralogists indiscriminately to two minerals, scarcely distinguishable by their external characters, the *carbonate* and *silicate* of zinc. The term, however, in the pharmaceutical sense, refers to the native *carbonate* only. The silicate is sometimes called *electric calamine*.

Properties, &c. Carbonate of zinc is found in various localities, but occurs most abundantly in Germany and England. It is found also in the United States. It usually occurs in compact or earthy masses, or concretions, of a dull appearance, readily scratched by the knife, and breaking with an earthy fracture; but sometimes it is found crystallized. Its colour is very variable; being, in different specimens, grayish, grayish-yellow, reddish-yellow, and when impure, brown, or brownish-yellow. Its sp. gr. varies from 3.4 to 4.4. Before the blowpipe, it does not melt, but becomes yellow and sublimes. When of good quality, it is almost entirely soluble in the dilute mineral acids, emitting a few bubbles of carbonic acid, unless it has been previously calcined. If soluble in sulphuric acid, it can contain but little carbonate of lime, and no sulphate of baryta. Ammonia, added to the sulphuric solution, throws down the oxide, and takes it up again when added in excess. If copper be present the ammonia will strike a blue colour, and in case of the presence of iron, the alkali will throw down the sesquioxide, not soluble in an excess of the precipitant. Carbonate of zinc is distinguished from the other variety of calamine (silicate) by dissolving in warm nitric acid without gelatinizing, and by not being rendered electric by heat.

Impurities. According to Mr. Robert Brett, calamine, as sold in the English shops, frequently contains only traces of zinc. He analyzed six specimens and found them to contain from 78 to 87.5 per cent. of sulphate of baryta, the rest consisting of sesquioxide of iron, carbonate of lime, sulphate (sulphuret?) of lead, and mere traces of zinc! When acted on by muriatic acid, the spurious calamine, in powder, evolved sulphuretted hydrogen, and was only in small part dissolved, the great bulk of it remaining

behind as sulphate of baryta. (*Amer. Journ. of Pharm.* ix. 173, from the *Brit. Annals of Med.*) Even the best calamine of the shops is impure, containing iron and copper, and various earthy matters. That which has been calcined to render it more readily pulverizable, contains little or no carbonic acid, and, therefore, is not entitled to the name of carbonate. In view of these facts, it would probably be an improvement if this preparation were expunged from the Pharmacopœias, and the pure carbonate, obtained by precipitation, substituted for it.

Composition. The crystallized variety is anhydrous, and consists of one eq. of carbonic acid 22·12, and one of protoxide of zinc 40·3=62·42. The compact and earthy varieties are said to contain one eq. of water.

Pharmaceutical Uses. Calamine requires to be brought to a state of impalpable powder before it can be used in medicine, and in this state it forms the *Prepared Carbonate of Zinc*, under which head its medical properties will be noticed.

Gen. Ch. Flowers spathaceous. Inner limb of the corolla with one lip. Anther double, with a simple recurved horn at the end. Germen inferior. Style enclosed in the furrow formed by the anther. *Loudon's Encyc. of Plants.*

Zingiber officinale. Roscoe, *Trans. Linn. Soc.* viii. 348; *Amomum Zingiber.* Willd. *Sp. Plant.* i. 6; Woodv. *Med. Bot.* p. 731. t. 250. The ginger plant has a biennial or perennial, creeping, tuberous root or rhizoma, and an annual stem, which rises two or three feet in height, is solid, round, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The scape or flower stalk rises by the side of the stem from six inches to a foot high, like it is clothed with oval acuminate sheaths, but is without leaves, and terminates in an oval, obtuse, bracteal, imbricated spike. The flowers are of a dingy yellow colour, and appear two or three at a time between the bracteal scales.

The plant is a native of Hindostan, and is cultivated in all parts of India. It is also cultivated in the West Indies, whither it was transplanted from the East. The flowers have an aromatic smell, and the stems, when bruised, are slightly fragrant; but the root is the portion in which the virtues of the plant reside. This is fit to be dug up when a year old. In the West Indies, the ginger crop is gathered in January and February after the stems have withered. After having been properly cleansed, the root is scalded in boiling water, in order to prevent germination, and is then rapidly dried. Thus prepared, it constitutes the ordinary ginger of commerce, or *black ginger*, as it is sometimes called, from the darkish colour which it acquires in the pro-

cess. It is imported into this country almost exclusively from Calcutta, and is known to the druggists by the name of East India ginger. In Jamaica another variety is prepared by selecting the best roots, depriving them of their epidermis, and drying them separately and carefully in the sun. This is called in the books *white ginger*, and is most highly valued. It reaches us from England, where it is said to undergo some further preparation, by which its appearance is improved. It is usually called in our markets *Jamaica ginger*. The root is also brought immediately from the West Indies in a recent state and sold by the confectioners. A preserve is made from ginger by selecting the roots while young and tender, depriving them of their cortical covering, and boiling them in syrup. This is occasionally imported from the East and West Indies. When good it is translucent and tender.

The *recent root* is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light ash colour, and marked with circular rugæ, internally fleshy and yellowish-white. It sometimes germinates when kept in the shops.

The *common, East India, or black ginger*, is of the same general shape, but has a dark ash-coloured wrinkled epidermis, which being removed in some places, exhibits patches of an almost black colour, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish and somewhat farinaceous. The powder is of a light yellowish-brown colour. This variety is most extensively used throughout the country.

The *Jamaica or white ginger* differs in being entirely deprived of epidermis, and white, or yellowish-white on the outside. The pieces are rounder, and thinner, in consequence of the loss of substance in their preparation. They afford when pulverized a beautiful yellowish-white powder, which is brought from Liverpool in jars. This variety is firm and resinous, and has more of the sensible qualities of ginger than the black. There is reason to believe that a portion at least of the white ginger of commerce has been subjected to a bleaching process, by which not only the exterior, but also the internal parts are rendered whiter than in the unprepared root. Trommsdorff found, in a specimen which he examined, evidences of the presence of chlorides, sulphates, and lime; and concluded that the bleaching was effected by chlorine, or the chloride of lime and sulphuric acid. Having macerated some black ginger in water, deprived it of the cortical portion, treated it for twenty-four hours with sulphuric acid diluted with nine times its weight of water, and finally placed it in a mixture of chloride of lime and water in which it was allowed to remain for two days, he found it, upon being washed and dried, to present an appearance closely resembling that of the finest white ginger, both on the surface and internally. (*Annal. der Pharm.* xvii. 98.) According to Brande, ginger is often washed in whiting and water; and Pereira states that it is sometimes bleached by exposure to the fumes of burning sulphur.

General Properties. The odour of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and ultimately disappear when the root is long exposed. The virtues of ginger are extracted by water and alcohol. Its constituents, according to M. Morin, are a volatile oil of a greenish-blue colour; a resinous matter, soft, acrid, aromatic, and soluble in ether and alcohol; a sub-resin insoluble in ether; a little osmazome; gum; starch; a vegeto-animal matter; sulphur; acetic acid; acetate of potassa; and lignin. The peculiar flavour of the

root appears to depend on the essential oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of very pure white starch may be obtained from it.

Those pieces of ginger which are very fibrous, light and friable, or worm-eaten, should be rejected.

Medical Properties and Uses. Ginger is a grateful stimulant and carminative, and is often given in dyspepsia, flatulent colic, and the feeble state of the alimentary canal attendant upon atonic gout. It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. When chewed it produces much irritation of the mouth, and a copious flow of saliva; and when snuffed up the nostrils, in the state of powder, excites violent sneezing. It is sometimes used as a local remedy in relaxation of the uvula, and paralysis of the tongue and fauces. Externally applied, it acts as a rubefacient. It may be given in powder or infusion. The dose of the former is from ten grains to a scruple or more. The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluidounces.

PART II.

PREPARATIONS.

THE preparation of medicines, which constitutes the art of Pharmacy, comes within the peculiar province of the apothecary. It is for his guidance that the various formulæ of the Pharmacopœia have been arranged, and to him that their directions are especially addressed.

A few general observations, therefore, of an explanatory nature, calculated to facilitate the progress of the pharmaceutic student, will not be misplaced under the present head. The duty of the apothecary is to obtain a supply of good medicines, to preserve them with care, to prepare them properly for use, and to dispense them. Our remarks will embrace each of these points.

The substances obtained from the mineral and animal kingdoms, and those furnished by the chemical manufacturer, are of a nature to admit of no general precepts as to their proper condition, which would not be suggested by the common sense of the purchaser. He must receive them as offered, and judge of their fitness for his purposes by his knowledge of the peculiar properties of each. The same remark applies to vegetable substances from abroad; but with respect to indigenous plants, the apothecary is frequently called upon to exercise his judgment in relation to their collection and desiccation, and will derive advantage from some brief practical rules upon the subject.

Collecting and Drying of Plants. The proper mode of proceeding varies according to the nature of the part used. The different parts of plants are to be gathered at the period when the peculiar juices of the plant are most abundant in them. In the *roots* of *annual* plants this happens just before the time of flowering; in the roots of *biennials*, after the vegetation of the first year has ceased; and in those of *perennials*, in the spring before vegetation has commenced. They should be washed, and the small fibres, unless they are the part employed, should be separated from the fleshy solid part, which is to be cut in slices previously to being dried. *Bulbs* are to be gathered after the new bulb is perfected, and before it has begun to vegetate, which is at the time the leaves decay. *Barks*, whether of the root, trunk, or branches, should be gathered in the autumn or early in the spring. The dead epidermis, and the decayed parts, are to be separated. Of some trees, as the slippery elm, it is the inner bark only that is preserved. *Leaves* are to be gathered after their full development, before the fading of the flower. The leaves of biennial plants do not attain their perfect qualities until the second year. *Flowers* should in general be gathered at the time of their expansion, before or immediately after they have fully opened; and some, as the *Rosa Gallica*, while in the bud. *Aromatic herbs* are to be gathered when in flower. Leaves, flowers, and herbs are to be gathered in clear dry weather, in the morning, after the dew is exhaled. *Stalks and twigs* are collected in autumn; *seeds* at the period of their full maturity.

Vegetables should be dried as rapidly as is consistent with their perfect preservation. *Fibrous roots* may be dried in the sun or in a room in which a heat of from 65° to 80° is maintained. *Fleshy roots* may be cut in transverse slices, dried in the open air till the moisture is nearly evaporated, and then placed in a stove heat not exceeding 100°, till perfectly dry and hard. *Bulbs* must have the outer membranes peeled off, and be cut in transverse slices and dried in a heat not exceeding 100°. *Barks, woods, and twigs* readily dry in thin layers in the open air. *Leaves* which are dry and thin do not require a heat exceeding 60° or 70°; those which are succulent may be exposed, by carefully and slowly raising the heat, to a temperature of 100°. *Flowers* must be dried carefully and rapidly in the shade; those of the most delicate texture and odour requiring the greatest care.

The following table, taken from the Edinburgh Dispensatory, presents the amount yielded by 1000 parts of the vegetables respectively mentioned, after being dried.

Roots of Angelica Archangelica	263	Leaves of Digitalis purpurea	180
Aspidium Filix Mas	500	Hyoscyamus niger	135
Inula Helenium - -	187	Melissa officinalis	220
Valeriana sylvestris -	316	Salvia officinalis	220
Bark of the Oak - - -	410	Tops of Mentha piperita	215
Elder - - - -	292	Flowers of Anthemis nobilis	338
Elm - - - -	375	Borago officinalis	96
Twigs of Solanum Dulcamara	308	Lavandula vera	510
Leaves of Atropa Belladonna	140	Sambucus Ebulus	256
Conium maculatum	185	Petals of Papaver Rhœas	84
Datura Stramonium	110	Rosa rubra - - -	330

Preservation of Medicines. The proper preservation of medicines is an object of the greatest importance to the apothecary. The aromatic gums and resins, and in general all the parts of vegetables, should be kept secluded from the light and as much as possible from the air, in perfectly dry rooms. Boxes or barrels, with close covers, will serve for holding *roots* and *barks*, after they have been thoroughly dried. *Roots* and *bulbs*, such as liquorice and squill, which are to be preserved fresh, should be buried in dry sand. *Leaves* and *flowers* should be kept in tin canisters or in light boxes lined with lead, tin, or zinc. The apothecary should regulate his purchases of perishable drugs by the demand which he finds for them, so as frequently to renew them. He should frequently examine the condition of every article, and on the slightest appearance of mouldiness, or of the attack of insects, should clean them, and again dry them perfectly in a heat of from 70° to 100°. This examination and re-drying, which should be made several times a year in respect to the articles which are most subject to change, should be made early in the spring of all the roots and barks and leaves in the shop; and those of which the sensible properties have become impaired should be rejected.

Drugs frequently require to be garbled, as it is termed, before they are in a proper state for use. *Senna* is to be separated from the stalks and legumes; *lichen* from moss, leaves, and sticks; *myrrh* from bdellium, &c.; *gum Senegal* from Bassora gum and a terebinthinate resin; *flaxseed* from clover seed; *seneka* from ginseng; *spigelia* from the stems, and both it and *serpentaria* from the adhering dirt. Seroons of cinchona should be examined, and the barks assorted before they are put by for use. *Gums* and *gum-resins* should be garbled, and the clear transparent tears preserved separately.

Weights and Measures. A precise acquaintance with the recognised

measures of weight and capacity is essential to the operations of the apothecary. The weights used by him in compounding medicines, are the troy pound and its divisions; those by which he buys and sells, the pound avoirdupois and its divisions. The former contains 5760 grains, the latter 7000 grains, so that 11 troy pounds are nearly equivalent to 9 pounds avoirdupois. The troy pound contains 12 ounces of 480 grains; the avoirdupois pound 16 ounces of $437\frac{1}{2}$ grains, eleven of the former being nearly equal to twelve of the latter. The troy ounce is divided for the use of the apothecary, into 8 drachms of 60 grains each, and the drachm into 3 scruples of 20 grains each. The United States and British Pharmacopœias all recognise the troy weights, and whenever in this work any term is used expressive of weight, it is to be understood as being of this denomination.

The measures used by the apothecary, in this country, are the wine pint and the gallon. The wine pint contains 28·875 cubic inches. The weight of a pint of distilled water at 62° Fahrenheit and 30° of the barometer, is 7289·7 grains, or 1 pound 3 ounces 1 drachm 29·7 grains troy, or 1 pound 289·7 grains avoirdupois. The gallon is divided into 8 pints, the pint into 16 fluidounces, the fluidounce into 8 fluidrachms, and the fluidrachm into 60 minims. The weight of a fluidounce of water is $455\frac{1}{2}$ grains, being 18 grains more than an avoirdupois ounce. A drop is generally though incorrectly considered as equivalent to the minim. Drops vary in size according to the nature of the fluid, and the size and shape of the lip from which they fall. A drop of water nearly equals a minim. A fluidrachm of antimonial wine will make, on an average, about 72 drops, one of laudanum 120 drops, and one of alcohol 138 drops. For a table showing the relative value of minims and drops, see the *Appendix*. Measures are employed, both by the United States and British Pharmacopœias, to express the quantity of liquids in nearly all their formulæ.

Fluids are to be dispensed from graduated measures, of which those holding from a fluidounce to a pint are hollow inverted cones; and those holding a fluidrachm, and graduated to every five minims, are cylindrical. For smaller quantities than five minims, a slender tube holding a fluidrachm may be used, having the aliquot parts divided off and marked with a diamond. Care should be taken to verify these instruments. The following approximate measures are used in prescribing medicines, viz. a wineglassful containing two fluidounces, a tablespoonful containing half a fluidounce, a dessertspoonful two fluidrachms, and a teaspoonful a fluidrachm.

Specific Gravity. The specific gravity of fluids affords one of the best tests of their purity. The instrument commonly used by the apothecary for ascertaining this is Baumé's hydrometer. This is a glass bulb loaded at one end and drawn out at the other into a tube on which the scale is marked. That used for alcohol is graduated by loading it until it sinks to the foot of the stem (which is marked zero) in a solution of one part of salt in nine parts of water. It is then put into water, and the place to which it sinks marks 10° of the scale, which is constructed from these data. The hydrometer for liquids heavier than water is made by loading it, so that in distilled water it shall sink to nearly the top of the stem. The place to which it sinks in a solution of 15 parts of salt in 85 parts of water is then marked as 15°, and the scale divided off. For a table exhibiting the value of these scales in specific gravities, see the *Appendix*.

The hydrometers commonly imported are so carelessly made that scarcely any two will agree, and little dependence is to be placed on their accuracy. A more certain method consists in weighing the liquid at a uniform temperature in a bottle, the capacity of which, in grains of distilled water, has

been previously ascertained. If a bottle is selected which will hold exactly 1000 grains of water at 60°, the weight in grains of the quantity of any liquid which it will hold will be the specific gravity of that liquid. Such bottles are sold in the shops. If one is not attainable, an ordinary vial may be used, and the specific gravity obtained by dividing the weight of the liquid examined by the weight of the water.

Gay-Lussac's centesimal alcoholmeter is a very useful instrument, being graduated so as to indicate the percentage of absolute alcohol in any mixture of spirit and water.

The specific gravity of a solid is ascertained by first weighing it in air and then in water, and dividing the former weight by the difference between the two.

Mechanical Division. One of the simplest means of preparing medicines, is their reduction, by mechanical means, to a state of minute division. This includes the various operations of pulverization, levigation, grinding, filing, rasping, sifting, bruising, slicing, &c.

The principal drugs which are sold in the state of powder, are pulverized by persons who pursue that occupation for a livelihood. The apothecary, therefore, is chiefly interested in knowing the loss sustained in this process. The following statement has been abbreviated from a table prepared by MM. Henry and Guibourt. One thousand parts of the substances mentioned yielded, when pulverized—

<i>Roots.</i>				<i>Vegetable Products.</i>	
Jalap	940	Cinnamon	890	Aloes	960
Rhubarb	920	Angustura	825	Tragacanth	940
Columbo	900	<i>Leaves.</i>		Opium	930
Liquorice root	900	Hemlock	800	Gum Arabic	925
Valerian	860	Savine	800	Scammony	915
Elecampane	850	Digitalis	790	Catechu	900
Gentian	850	Belladonna	785	Liquorice (extract)	810
Florentine orris	850	Senna	720	<i>Animal Substances.</i>	
Rhatany	850	Henbane	530	Castor	900
Calamus	840	<i>Flowers.</i>		Spanish flies	850
Virginia snakeroot	800	Chamomile	850	<i>Mineral Substances.</i>	
Ipecacuanha	750	Saffron	800	Red oxide of mercury	980
Squill (bulb)	820	<i>Fruits.</i>		Red sulphuret of mer-	
<i>Barks.</i>		Mustard	950	cury	950
Cinchonia, pale	875	Black pepper	900	Arsenious acid	950
—, red	880	Nux vomica	850	Sulphuret of antimony	950
—, yellow	900	Colocynth	500	Tin	825

For the greater part of those drugs that are powdered in the shops, iron, brass, glass, or Wedgwood mortars are to be used; the two former for hard substances requiring repeated blows; the latter for those which are friable and can be reduced to powder by trituration. The interior surface of the mortar should be concave and nearly spherical, and care should be taken not to impede the operation by overloading and clogging the pestle. In powdering acrid substances, the mortar should be covered with a board perforated in the centre for the pestle, or with a large piece of pliable leather tied round the top of the mortar and the handle of the pestle, so as to allow of the free motion of the latter. The operator should guard himself against the fine particles of very acrid substances, by standing with his back to a current of air, and covering his nostrils with a wet cloth. Various means are used to facilitate the operation of powdering. All vegetable substances must be carefully and thoroughly dried. Resins, gum-resins, and gums, must be powdered in cold frosty weather. Tragacanth and nux vomica

must be dried in a stove heat, and powdered while hot. The fibrous roots, as liquorice and marshmallow, should be previously shaved into thin transverse slices. Agaric is to be powdered by beating it into a paste with water, then drying and triturating it. Cloves and the aromatic seeds may be ground in a hand mill and afterwards triturated. Squill and colocynth, the comminution of which is sometimes aided by soaking them in mucilage of tragacanth and then drying, are best powdered in a dry atmosphere, after being thoroughly dried in a stove heat. Camphor requires the addition of a few drops of alcohol. The efflorescent salts may be obtained in the state of fine powder by exsiccation, and those which are insoluble in alcohol, may be precipitated by it, in an impalpable powder, from their aqueous solutions.

Care should be taken in powdering, previously to separate the inert portions and impurities, and to mix intimately the whole of the powder which is reserved for use. The central woody fibre of ipecacuanha and other roots, the virtues of which reside in the bark, is to be rejected. The first portions of those barks to which lichens and the dead epidermis adhere, are inert; as are also the last particles of the fibrous roots and barks. The outer coat of the aromatic seeds is to be reserved, and the inner albuminous part rejected as inodorous.

In the operation of powdering, the fine particles are to be separated from time to time by sifting. Fine sieves should be made of that sort of raw silk called bolting cloth; coarser ones of wire, hair cloth, or gauze. Valuable or aromatic powders should be passed through box sieves, which are sieves provided with covers for the top and bottom, that shut up so as to prevent all waste.

Ivory, horn, nux vomica, wood, and iron, are prepared for pharmaceutic purposes by filing or rasping; guaiacum wood by turning in a lathe; roots, stalks, and leaves, by cutting with a large pair of shears, such as is used by the tinsplate workers; or with a large knife fixed in a frame at one end, and furnished with a long handle at the other. Tin and zinc are granulated by melting them, and strongly agitating whilst they are cooling; carbonate of potassa by stirring the concentrated solution with a rod as it hardens.

Earthy insoluble substances are conveniently reduced to powder by *levigation*. This is performed by moistening them with alcohol or water, and rubbing them on a hard flat stone with a muller or rubber of the same material. The powder may be rendered impalpable by agitating it with a large quantity of water, and pouring off the liquid to settle, after the coarser particles have subsided. The fineness of the powder depends on its specific gravity, and the length of time which elapses before the liquid from which it subsides is drawn off. This last operation is termed *elutriation*, and the thick pasty mass which remains, is usually dropped on an absorbent surface, and dried in the shape of small cones. Vanilla, mace, and other oily aromatic substances, may be rubbed to powder with sugar; magnesia and white lead, by friction on a wire or hair sieve.

Separation of Solids from Liquids. This is another mechanical operation which is frequently resorted to in practical pharmacy. It includes the processes of decantation, filtration, straining, expression, clarification, &c.

Solids may be separated from fluids, when there exists no chemical action between them, by being allowed to subside. The supernatant liquid may then be carefully poured off; or it may be drawn off by a syphon; or separated by filtering. Either the last operation, or expression by a stronger force, is necessary to separate the whole of the liquid.

Jars larger at bottom than at the top, and furnished with a lip for pouring, are sold in the shops, and will be found very useful for precipitations.

When the powder subsides very slowly, the precipitation may be greatly hastened by the addition of a small quantity of the solution of gelatin. Gelatinous precipitates, such as alumina, must be filtered to clear them from the adhering liquid.

The most convenient material for a filter is unsized paper. This is to be folded into a cone and placed in a glass funnel. It will serve for filtering tinctures, wines, saline solutions, watery infusions, and essential oils. In some cases it may be necessary to place a small cone of the same material outside of the large one, in order to strengthen it. When the liquid is too viscid to pass readily through paper, a cotton or woollen bag of a conical shape may be used. Acids may be filtered through a layer of fine siliceous sand, supported in the neck of a glass funnel by pieces of glass gradually decreasing in size. Castor oil, syrups, and oxymels may be readily filtered through coarse paper made entirely of woollen shreds. Melted fats, plasters, resins, and wax, may be *strained* through muslin stretched over a square frame or a hoop. Small sieves of fine bolting cloth serve for straining emulsions, decoctions, and infusions; and a temporary strainer for these purposes may be made by fastening a piece of muslin between the upper and lower parts of a common pill box, and then cutting off the ends so as to leave the rim only of the box around the muslin. The filtration of viscid substances is facilitated by heat. Filtration through bone black is practised for muddy or dark coloured liquids.

Much inconvenience is often experienced in the filtration of hot saturated saline solutions, by the cooling of the liquid and consequent crystallization of the salt in the filter and neck of the funnel. To obviate this, the tin apparatus represented in the wood cut has been contrived by Professor Hare. The vessel is filled with hot water, which is kept at a boiling heat by a spirit lamp placed under the cavity having the shape of an inverted funnel. A glass funnel with a filter is placed in the other cavity, and the liquid passes through rapidly. In filtering alcoholic solutions, it is necessary to protect the liquid from the flame of the lamp, and for this purpose the partition underneath has been added.

No apothecary will be without this useful apparatus. Frames of various sizes for holding funnels and filters will be found very useful; the wood cut represents the one commonly used. The efflorescence of saline solutions on the edge of the filtering paper may be prevented by dipping it in melted tallow or lard.

The filtration of liquids which are altered by exposure to the air, requires much caution. A very simple method of accomplishing it, is to insert a slender tube of glass into the funnel, long enough to reach below the neck, while the upper part is nearly as high as the top of the funnel.

The space between the tube and the neck must be filled with bits of glass and fine sand, so as to form a good filtering bed; the liquid is to be poured in, and the top of

the funnel covered with a plate of glass. If this be luted on, and the funnel luted into the neck of a bottle, the process will be performed with perfect accuracy.

Expression is required to separate the last portions of tinctures or infusions from the dregs. A screw press is used for this purpose. The substance to be pressed is put into a cylinder of strong sheet tin, the sides of which are pierced with small holes. This is placed on a square tray of tin having a lip for pouring. A block of wood fits into the cylinder and is placed on the top, and the whole is put under the screw press, the pressure of which is gradually brought to bear upon it.

This press is to be used for expressing the juices of fresh plants, which, previously to being pressed, must be well beaten in a mortar, and water added to those which are hard and dry.

The expressed oils are obtained by bruising the seeds which contain them, and enclosing the bruised mass in strong bags which are placed in a firm hollow frame and subjected to strong sudden pressure by driving up a wedge. Expressed oils are clarified from mucilage by boiling them with water.

Liquids in general are rendered clear by the addition of some coagulable substance, such as milk or an aqueous solution of ichthyocolla. The white of an egg, beaten up with water, will coagulate by a gentle heat, and clarify any liquid with which it has been mixed. The vegetable acids will clarify many of the expressed juices of plants.

Separation of Liquids. Liquids which have no chemical affinity, and differ in specific gravity, may be separated by allowing them to remain at rest in the separating funnel represented in the annexed figure, and then drawing off the heavier fluid. Another very convenient method of separating fluids is by means of the separatory figured in the wood cut in the margin. The last drops of the heavier fluid may be drawn off by means of this instrument.

Application of Heat. The most efficient and economical means of obtaining heat is a subject of great importance to the pharmacist, on account of the variety of processes in which it is required.

With the small furnaces, which are now made of fire clay, of various patterns and sizes, almost all the operations of the laboratory which require heat, can be performed. The fuel used is charcoal, although anthracite will burn in those of a larger size, and is to be preferred where a uniform heat is necessary for several hours. The apothecary should be provided with a complete set of these useful utensils, including one with a dome for a reverberatory furnace. By adding a pipe several feet in length to this, and urging the fire with a pair of double bellows, the heat may be raised to that of an air furnace. A small pipe of sheet iron with a cone at the lower end, as in the figure, to fit on the furnace, will be found an excellent means of obtaining an intense heat in those of the smallest size. For operations on a smaller scale, the most convenient means of obtaining heat is by an alcoholic lamp. Alcohol burns without smoke or smell, and is almost as cheap a fuel as oil, to which it is on every other account preferable.

The annexed figures represent the usual forms of spirit lamps. The larger one will be found very useful in heating spatulas for spreading plasters. For supporting the substance to be heated, iron tripods of various heights and sizes must be provided. These should be furnished with sets of concentric rings as in the figure, for vessels of different sizes. A very convenient support is the stand and ring figured in the wood cut, which will answer either for a spirit lamp, or a small furnace made from a black lead crucible as in the figure.

The temperature required in pharmaceutical processes, seldom exceeds a red heat; and the vessels used are crucibles of silver, porcelain, Wedgwood ware, black lead,

and fire clay (Hessian crucibles). Silver is used for the *fusion* of potassa, porcelain for nitrate of silver, and black lead and Hessian crucibles for the metals, glass of antimony, sulphuret of potassium, and the ordinary operations which require a great heat. They are each liable to objections; silver fuses too readily; porcelain and Wedgwood ware do not bear sudden changes of temperature; black lead, which bears these changes, is destroyed by saline substances, and burns in a current of air; and the Hessian crucibles are so porous as to absorb and waste much of the fused substance. The crucibles should be covered with a lid or an inverted crucible, and should be supported at a little distance from the bottom of the grate, and surrounded and covered with ignited coals. *Liquefaction* is performed in open earthen, copper, or iron vessels, and care must be taken not to raise the heat so as to char or inflame the substance.

A *sand bath* is an indispensable part of the pharmaceutic apparatus. It is usually an iron pot or a shallow vessel of sheet iron capable of holding sand to the depth of four or six inches. It serves to regulate the action of the heat on vessels which do not bear a rapid change of temperature. It is sometimes heated to a red heat, as in preparing the mineral acids, though more frequently used for the evaporation of saline solutions and vegetable juices. The *water bath* is to be used in all cases in which a heat above that of boiling water would be injurious. A very convenient one, figured in the wood cut, consists of two copper vessels, the upper one of which is well tinned. Where a temperature above that of boiling water

and not exceeding 228° is required, the water bath may be filled with a saturated solution of common salt.

The common still and worm, the vessels in general use for *distillation*, are too well known to need description. A convenient still or alembic for small operations, which may be heated by a spirit lamp, is figured in the wood cut. The top of the head is kept filled with cold water, and all escape of vapour is prevented by having an inner ledge to the still, and filling the space in which the head fits with water. The condensation of all the vapour is secured by adapting a worm or a long tube to the apparatus. The boiler of this still may hold one or two gallons, and it will be found a very useful means of recovering the alcohol in making alcoholic extracts. It may easily be converted into a water bath by fitting on the top of the boiler a vessel of convenient form.

For the extrication and condensation or absorption of gaseous fluids, a retort and a series of three necked (or Woulfe's) bottles are used. The bottles are partly filled with water and become saturated in succession. As the tubes which convey the gas are plunged nearly to the bottom of the liquid in the bottles, there is danger, when the operation is complete, and a vacuum formed in the retort, of the water being driven by the atmospheric pressure in the last bottle, back through the whole series, so as to fill the retort. To prevent this, safety tubes must be fitted to the retort and the bottles. Those for the bottles are straight tubes, dipping a small depth into the liquid; that for the retort is the common Welter's tube of safety. When the common glass retort and receiver are used for the distillation of fluids, care should be taken not to apply the luting until the atmospheric air is expelled. The chief objects to be aimed at are to keep

the body of the retort hot, and the neck and receiver cool. A hood of pasteboard or tin, as represented in the figure, will much facilitate the former; and the latter will be gained by keeping the neck and receiver wrapt in wet cloths, on which a stream of cold water is kept running. This may be conveniently done by means of a syphon, made by dipping one end of a strip of cotton or woollen cloth in a vessel of water, and allowing the other end to hang down upon cloths bound loosely around the receiver or the neck of the retort.

When the object of distillation is to preserve the residuum, and this is liable to injury from heat, as is the case with vegetable extracts, the operation is best performed in *vacuo*. For this purpose the still and recipient are made so as to form an air-tight apparatus, and the latter is furnished with a stop cock, which is kept open until the whole of the atmospheric air is expelled by the vapour. It is then closed, and a vacuum formed and maintained in the recipient by surrounding it with cold water. The distillation is carried on in this manner at a much lower temperature than ordinary.

The vapours of some volatile solids have the property of condensing into the solid form, either in mass, or in a state of the most minute division. The operation in which this occurs, is called *sublimation*. When the product is compact, it is called a *sublimate*, when slightly adhering, it is called *flowers*. The operation is generally performed in a sand bath; and the

apparatus consists of two vessels fitting each other, one being inverted over the other. The shape, size, and depth of the vessels, and the degree of heat to be applied, are regulated by the nature of the substance operated on.

Lutes. The most precious material for the chemist is glass, the transparency, insolubility, and hardness of which fit it for almost every purpose. It is often necessary to strengthen it by means of lutes, which will bear a heat at which glass would soften; and the application of lutes for this purpose, and for securing the junctures of tubes and vessels, is also an important part of the pharmaceutic art. Those lutes which are required for coating vessels exposed to a great heat, are made of Stourbridge clay. The clay is made into a paste with water mixed with chopped straw, and successive coats applied as they become dry. Earthenware vessels may be rendered impervious to air or vapours, by brushing over them a thin paste made of slaked lime and a solution of borax containing an ounce to the half pint. This is allowed to dry, and the vessel is then coated with slacked lime and linseed oil, beaten till the mixture becomes plastic. Earthenware retorts thus coated, may be safely used more than once, the coating being renewed every time.

Fat lute is applied to the joinings of apparatus to prevent the escape of corrosive vapours. It is made like glazier's putty, pipe clay being substituted for whiting. It will bear a considerable heat, and great care must be taken that the part where it is applied be perfectly dry. If it is to be exposed to heat, slips of moistened bladder must be wrapped round it and secured with twine.

Roman cement and plaster of Paris may be applied in the same manner as fire clay. When used for securing the joinings of apparatus, a coating of oil or wax will render them air-tight.

A very useful lute is formed by beating the white of an egg thoroughly with an equal quantity of water, and mixing it with some slaked lime in the state of fine powder, so as to form a thin paste. This must be spread immediately on slips of muslin and applied to the cracks or joinings intended to be luted. It soon hardens, adheres strongly, and will bear a heat approaching to redness without injury. A leak in this lute is readily stopped by the application of a fresh portion. Solution of glue, or any liquid albuminous matter may be used in place of the white of eggs.

An excellent cement for surfaces of iron, consists of one part of sulphur, two of sal ammoniac, and eighty of iron filings, mixed together and slightly moistened. It is rammed or caulked into the joints, and solidifies perfectly in time.

White lead ground in oil, is an excellent cement for broken glass. Spread upon linen, it forms a good coating for a cracked surface, but dries slowly.

Strips of bladder macerated in water adhere well to glass, and are very useful.

A mixture of whiting and paste or gum water, spread upon strips of paper, forms an excellent luting for joinings not exposed to acrid vapours or a great heat.

A useful lute is formed by spreading a solution of glue on strips of cloth, and coating them, after they are applied, with drying oil.

Linseed meal beaten into a uniform mass with milk, lime-water, rye paste, or thin glue, and applied in thick masses, adheres well; and when dry will resist most vapours.

Cup cement is made of six parts of resin, one part of yellow wax, and one of Venetian red. It is a very useful cement for fastening metals or wood to glass, and for rendering joints impervious to water. *Soft cement* is used for

the same purposes, and is made of yellow wax, melted with half its weight of turpentine, and coloured with a little Venetian red. It is very useful for rendering the stoppers of bottles perfectly air-tight:

Chemical Operations. Some of the chemical processes conducted by the apothecary, have been explained in the former part of this introduction. It remains to notice some others in constant or frequent use. *Infusion* is the subjecting of a substance containing soluble principles to the action of a menstruum, which is usually water. Hot infusions are made by pouring boiling water on the substance, and allowing it to remain in a covered vessel till cold. Cold infusions are made with cold water, and require several hours to attain their full strength. *Maceration* is the term employed to denote the action of liquids upon medicines, when allowed to remain upon them for some time, at a heat of from 60° to 90°. *Digestion* is the name given to the same operation, when conducted at a temperature of between 90° and 100°. It is commonly performed in glass bottles or flasks, and a common fire or stove heat is employed. *Decoction*, or boiling, is sometimes employed in extracting the virtues of plants, but is often disadvantageous, as most of the proximate principles of vegetables are altered by it, especially when long continued. Where it is practised, the ebullition should generally be continued for a few minutes only, and the liquid be allowed to cool slowly in a close vessel.

From the solutions of vegetable principles obtained by these different processes, extracts are prepared by slow *evaporation*, so as to *inspissate* the liquid. This process should, as has already been mentioned, be always conducted at a heat not exceeding that of boiling water. Evaporation at a gentle heat is also performed for the *concentration* of saline solutions, in order to promote their *crystallization*. The proper degree of concentration is attained, if a drop of the liquid on a cold glass plate deposits crystals. The slower the evaporation and the cooling, and the greater the quantity operated on, the larger will be the crystals.

Water which is saturated with any salt is still capable of dissolving other salts. It is in this way, by washing crystals of impure salts with their own saturated solutions, that the crystals are purified. Fine silky crystals, which retain their mother water by capillary attraction, must be dried by strong expression in a linen bag. The finest silky crystals may be entirely freed from their adhering liquid by placing them in a funnel which fits closely to one of the necks of a double mouthed bottle, and fitting a tube to the other, through which air is drawn. The current of air, in passing through the funnel, carries the water with it, and dries the crystals perfectly.

Lixiviation is a process used for separating a *soluble* from a porous *insoluble* body. It consists in placing the substance to be lixiviated in a vessel, the bottom of which is covered with straw, &c., pouring water upon it, allowing the water to remain until saturated, and then drawing it off through an opening at the bottom of the vessel. It is found that if fresh water be poured on without disturbing the mixture in the vessel, it does not mix with the liquid already there, but percolates the solid particles, driving the saturated liquid before it; so that, for example in lixiviating wood ashes, if a gallon of water had been poured upon the ashes, and allowed to become saturated with the alkali, we shall obtain by this mode of proceeding, a gallon of strong ley, and immediately thereafter the water will become almost tasteless. This fact has been applied to the service of the pharmacist, and has led the way to some valuable improvements in the mode of extracting the medicinal qualities of plants.

The operation is called by the French the *method of displacement*.

The figure in the margin represents Boullay's filter, constructed on this principle. It consists of a long tin vessel, nearly cylindrical, but narrower at the lower end, which has a funnel shaped termination, for the purpose of being inserted in the neck of a bottle. A metallic plate pierced with holes, like a cullender, and having a handle in the centre, fits accurately in the lower part of the cylinder. Upon this, previously covered with a thin layer of carded cotton, is placed the substance upon which it is intended to operate, and which should be coarsely powdered or mashed in a mill. It must then be saturated with the menstruum, which is done by pouring on the liquid from time to time until it will absorb no more, and then allowing them to remain for a few hours in contact. On the top of the powder is placed another similarly pierced plate, and fresh portions of the menstruum are gradually and successively added, until all the sensible properties are extracted. The first portion, that with which the powder was mixed, flows off very highly concentrated, while the next is much less so, and the successive infusions rapidly become weaker. A stop-cock near the lower end of the instrument, as represented in the second figure, will be convenient for regulating the discharge of the fluid. A single example will show the value of this process. The Messrs. Boullay, by subjecting four ounces of bruised cinchona to displacement with half a pint of water, and then adding four half pints in succession, obtained the following results:

1st	Half pint	yielded	3 drs. 48 grs. dry extract.
2d	Do.	"	1 dr. 5 grs. Do.
3d	Do.	"	15 grs. Do.
4th	Do.	"	9 grs. Do.
5th	Do.	"	7 grs. Do.

Cylinders 14 inches long by $2\frac{1}{2}$ in width at the base, 14 inches by 4, and 17 by 6, are convenient sizes for ordinary use. When it is wished to operate upon a fine powder, it will be found advisable to increase the height of the column of liquid by making the top of the cylinder air-tight, and inserting a tin tube several feet long, which must be kept filled with the liquid. All the substantial advantages of this method may, however, be generally obtained without pressure, by using the filter of Boullay. For operating upon small quantities of a substance, an adapter or the broken neck of a retort may be used by loosely stopping the lower and smaller end with a piece of cotton.

Soubiran has adapted to Boullay's filter a receiver of tin, from which the filtered liquor may be drawn off by a stop-cock at the most dependent part. An apparatus of this kind is represented in the margin.

Precipitation is sometimes mechanical, as in the process of *levigating* and *elutriating* the carbonate of lime, and sometimes chemical, as in the preparation of this salt by decomposing

chloride of calcium. When a precipitant is directed to be added until no further precipitation takes place, the fact may be ascertained by taking a drop of the liquid on a glass plate, and trying it with the precipitant. The formation of a precipitate is often much assisted by agitation or by heat. The separation of the supernatant liquid from the precipitate is most effectually accomplished by means of a syphon. When the liquid is a saline solution, it is necessary to wash the precipitate until the water exhibits no trace of the salt. In doing this, great care must be taken to select the purest and clearest water, and the ultimate drying of the precipitate must be performed in a filter, or on a porous stone.

The apparatus figured in the margin is very convenient for procuring a constant and gentle stream of water in the washing of precipitates, and in clearing crystals of the impurities of their mother water. It consists of a syphon having legs of equal length, one of which is inserted in an air-tight bottle nearly filled with water, and the other dips into the funnel. A straight open tube is also inserted in the bottle, the lower end of which is about half an inch or an inch above the end of the syphon. It is obvious that the water will run from the syphon no longer than till the water in the funnel is level with the end of the straight tube.

The operations which require a heat greater than that used in digesting, are *liquefaction*, *fusion*, *calcination*, *ustulation*, *incineration*, *distillation*, and *sublimation*.

Liquefaction is the melting of those substances that become soft previously to fusion, as wax, tallow, plasters, &c. The heat employed is always below that at which charring takes place.

Fusion is the melting of those substances which pass immediately from the solid to the fluid state. It is employed in pharmacy in preparing the nitrate of silver and caustic potassa for casting into cylinders. The former must be melted in a porcelain, the latter in an iron crucible. The moulds in which they are cast are formed of two thick plates of cast iron, with semi-cylindrical grooves that fit accurately to each other. Fusion is also used in preparing the glass of antimony.

Calcination is a term applied to the changes produced in mineral substances by intense heat, not attended with fusion and leaving a solid residue, and is often synonymous with oxidation. The term *ustulation* is restricted to the metallurgic operations of roasting ores, to drive off the volatile matters, as arsenic, &c. Calcination is often used to express the ustulation or burning of carbonate of magnesia. This is to be performed in an earthen vessel at a red heat. Exposure to the heat of a potter's furnace during the burning of the kiln, is an excellent mode of performing the operation. More commonly, the magnesia is burnt in an iron pot, which is objectionable, as the heat soon oxidates the iron, and the oxide scales off and mixes with the magnesia, which is seldom free from iron when prepared in this way.

Incineration, as the name expresses, is the operation of burning substances for the sake of their ashes. It is performed in obtaining the phosphate of lime—the Cornu Ustum of the London Pharmacopœia. The bones are burnt in an open fire until all the inflammable matter is consumed.

Distillation and *sublimation* have already been spoken of. The former is used for separating a more volatile liquid, as ether or alcohol, from one

less so; for impregnating a liquid with the volatile principles of plants, to the exclusion of other principles, as in the preparation of aromatic spirits and waters; and for separating, by means of aqueous vapour, the essential oils and volatile proximate principles of the vegetable kingdom. The first process is termed *rectification*. When the second process is repeated with the same liquid and a fresh quantity of the plant, the operation is termed *cohobation*. In submitting the solid parts of vegetables to distillation in the two latter processes, it will be found advisable to expose them to the action of vapour on a grate or in a basket, so as to preserve them from touching the bottom of the still, where they would be liable to be heated so as to become empyreumatic. Distillation is also used for obtaining the volatile products which result from the decomposition by heat of substances of animal or vegetable origin. The *oils* which are obtained in this manner are called *empyreumatic oils*. Sometimes the result is an acid, as the succinic acid, and sometimes the volatile alkali, as in the destructive distillation of animal substances.

Dispensing of Medicines. A large portion of the operations of the apothecary is performed in the shop extemporaneously. In dispensing medicines from the counter, he is continually called upon to put his previous knowledge in practice, and often to substitute extemporaneous for the regular officinal formulæ. There is no part of his business which requires for its proper performance so much ready knowledge and so accurate a judgment. A few directions, suggested by running the eye over the list of preparations of the Pharmacopœia, may be found useful.

It may sometimes be necessary for the apothecary to make extemporaneously an aromatic water, which is not usually kept in the shops. In this case, he is to prepare it by rubbing a drop of essential oil with one or two grains of carbonate of magnesia, for every fluidounce of water, and filtering.

It is sometimes desirable to apply plasters prepared from the narcotic herbs. These may be made extemporaneously by mixing the soft extracts of the plant with about an equal weight of melted adhesive plaster, keeping the mixture soft, and stirring it until the moisture is evaporated. The most suitable material on which to spread plasters is soft white leather. A margin of half an inch should be allowed to remain around the plaster. The plaster iron or spatula may be heated over the large spirit lamp, figured in page 759. A skilful apothecary will be able to spread the plaster uniformly and evenly, without overheating it so as to penetrate or corrugate the leather. A convenient instrument for determining the size and preserving a straight edge, consists of two squares made of tin and graduated to inches, as in the annexed figure: or pieces of paper may be cut out and pasted on the leather, so as to enclose a space of the required dimensions. The plaster should first be melted on a piece of brown paper, and then transferred to the leather, in order to prevent its being applied at too great a heat.

Decoctions and infusions are often ordered in prescriptions in the quantity of a few ounces. A very convenient vessel for preparing them in is the common nursery lamp, which consists of a cylindrical vessel, open at the side for a spirit lamp, and at the top to receive a tea pot or tin boiler.

Infusions and decoctions may be kept during the hot weather, and for many months, by straining them *while hot*, and pouring them at once into bottles

provided with accurately ground stoppers. The bottle must be entirely filled, the stopper being made to displace its own bulk of the liquid. A common bottle with a perforated cork stopper may be used, provided the hole be instantly closed, and the cork covered with sealing wax. The hotter the liquid and the freer from air bubbles, the better will the infusion be preserved.

The neutral mixture is known to be saturated perfectly, when it does not affect litmus paper either in its blue state or when reddened by acid. For preparing this and the effervescing draught, it is advisable to keep in the shop a solution of carbonate of potassa, containing an ounce to the pint. The silica which this salt contains precipitates after a few weeks, and leaves a perfectly clear solution, whereas that prepared at the time it is to be used, always becomes turbid after being saturated. The carbonic acid which is extricated on preparing the neutral mixture, combines at first, without effervescence, with the remaining carbonate and forms a bisalt. This circumstance may lead, unless the solution be tested, to the supposition that the mixture is saturated.

Powders are often mixed together with difficulty, by means of a pestle and mortar, on account of their differing greatly in weight, or of their softness and compressibility. In these cases, frequent stirring with a pallet knife becomes necessary to produce a perfect mixture. In dividing powders into doses, it is very desirable to fold the packages neatly and of a uniform size. The powder folder represented in the figure is very useful for this purpose. It may be made of mahogany or other hard wood.

It is important to the apothecary to ascertain the best means of combining substances which have no affinity for each other. This can often be done by means of a third substance. Water can be saturated with camphor by means of carbonate of magnesia, and an aqueous mixture of any strength may be made with it, by triturating the camphor with magnesia and shaking the mixture before using it. Camphor softens the gum-resins and solid fats and oils, and may be rendered permanently miscible with water in considerable quantity, by trituration with a fifth part of myrrh. In preparing oily emulsions in which gum Arabic or gum and sugar are the medium, a sufficient quantity of water must be added to convert them into a thick mucilage before adding the oil, which must then be thoroughly mixed with it, and the remaining water added gradually with great care. Sulphuric ether is rendered more soluble in water by trituration with spermaceti. The mixture should be filtered to separate the superfluous spermaceti. Mixtures that contain the resinous tinctures, should also contain syrup, with which the tincture should first be mixed, and the water then added very gradually. If a mixture contains laudanum and a fixed oil, the former should be first mixed with the syrup, and the oil afterwards incorporated, and lastly the water. The mixture will not otherwise be uniform.

In ordering pills, care must be taken to avoid the use of deliquescent salts, and to deprive those which are efflorescent of their water of crystallization. The mass must be thoroughly incorporated previously to being divided; and this is particularly important when extracts of different degrees of hardness enter into the composition. A section of the mass should be throughout of uniform colour and consistency. Pills are to be rolled and preserved in powdered liquorice root, which ought to be kept for use in a tin box with a perforated lid, like a pepper box. When pills are of too soft a consistence, a little liquorice powder may be incorporated with them to render them more firm. Pills, into the composition of which gum Arabic enters, should be

softened with syrup and not with water, as the latter renders the mass difficult to roll.

The proper cleanliness of his vessels, is an object of great importance to the apothecary. Open vessels, as mortars and measures, are easily cleansed, and should be wiped dry immediately after being washed. Fats and resins are easily removed by pearlash, or tow and damp ashes, or sand. Red precipitate and other metallic substances, may be removed by a little nitric or muriatic acid. Bottles may be cleansed from the depositions which accumulate on their sides and bottom from long use in the shop, by a few shreds of grocers' paper and a little clean water. They are to be shaken so as to give the paper and water a centrifugal motion, which effectually removes the dirt from the sides. They may be freed from oil by means of a little strong nitric acid, after the action of which water will thoroughly clean them. Long sticks, with sponge or dry cloth at the end, should be provided for wiping dry the interior of flasks and bottles. A wire, bent at the end into a sort of hook, will be found useful for getting corks out of bottles. A loop of twine will also be found a very convenient means of effecting the same object. When the glass stopper of a bottle is fast, it may often be loosened by gently tapping its sides alternately with the handle of a pallet knife. Sometimes a drop or two of oil, alcohol, or water, will soften or dissolve the cementing substance. It will sometimes answer to wrap the stopper in a cloth, insert it in a crevice or hole in a table or door, and twist the bottle gently and dexterously. Sometimes the stopper may be loosened by quickly expanding the neck in the flame of a lamp, and tapping the stopper before the heat has reached it. When the stopper of a bottle containing caustic alkali adheres in consequence of the neck not having been wiped thoroughly dry, it is almost impossible to loosen it, and the neck must be cut off.

The apothecary should be provided with pallet knives of wood, bone, and horn, as well as of steel. It should be an invariable rule to clean every knife and graduated measure immediately after it is used, and to put the dirty mortars apart from those which are clean. Too much particularity and order in all the minute details of the shop cannot be practised. The counters and scales should be cleaned once a day, and brushed as often as they become dusty. The bottles should be replaced as soon after being taken down and used as possible, and should on no account be changed from their accustomed place on the shelf. For the proper preservation of leaves, flowers, aromatic powders, calomel, and other medicines to which light is injurious, the bottles should be coated with tin foil or black varnish.

No apothecary should be destitute of a set of troy weights; as without them he will find it difficult to comply with the official directions for the preparation of his medicines. In dispensing medicines, no vial or parcel should be suffered to leave the shop without its appropriate label; and this, in the case of prescriptions, should always be the physician's direction as to the manner of taking it, and not the name of the medicine, unless it be so directed by him. The prescription or a copy of it should be retained and numbered, and the same number marked on the bottle or parcel. Every thing connected with the shop, and the dispensing and putting up of medicines and parcels, should be characterized by *neatness, accuracy, system, and competent knowledge.*

The apprentice who desires to qualify himself for his business should carefully study Turner's Elements of Chemistry, and Faraday's invaluable treatise on Chemical Manipulation, which may be termed the hand-books of his profession.

D. B. S.

GENERAL OFFICIAL DIRECTIONS.

As all the processes of the United States and British Pharmacopœias are either described or fully detailed in the following pages, it is proper that the prefatory explanations of the several Pharmacopœias should be introduced in this place, in order that the reader may be prepared to understand the precise signification of the terms employed.

The Pharmacopœias recognised in this work unite in the use of the *troy* or *Apothecaries'* pound, and its divisions of ounces, drachms, scruples, and grains, for the expression of weights. Upon this subject the United States Pharmacopœia has the following note, to which the attention of Apothecaries is particularly invited. "It is highly important that those engaged in preparing or dispensing medicines should be provided with *Troy* weights of all denominations; but, when these are not to be had, the same end may be attained by calculating the Avoirdupois pound at 7000 Troy grains, and the Avoirdupois ounce at 437·5 grains, and making the requisite allowance. Thus 42·5 grains added to the Avoirdupois ounce will make it equal to the Troy ounce, and 1240 grains deducted from the Avoirdupois pound will reduce it to the Troy pound." As the common weights of the country are the avoirdupois weights, and every apothecary is in possession of the lower denominations of the Apothecaries' weight, viz. grains, scruples, and drachms, there can be no difficulty in complying with the official directions. Both in the *United States* and *British* Pharmacopœias, the quantity of fluids is generally indicated by the liquid measure, consisting of the gallon and its divisions of pints, fluidounces, fluidrachms, and minims. It is highly necessary that the apothecary should understand that this distinction is rigidly observed in all the details which follow, and that whenever the simple terms pound, ounce, and drachm are employed, they must be considered as belonging to the denomination of troy weight. This caution is the more necessary, as these terms are often confounded with the corresponding divisions of liquid measure, viz. the pint, fluidounce, and fluidrachm. (See tables of weights and measures in the Appendix.)

The London and Edinburgh Colleges, in the last edition of their Pharmacopœias, have adopted the imperial gallon and its divisions, instead of the wine gallon which they before employed. In the United States and Dublin Pharmacopœias the wine gallon is still retained. This discrepancy is very unfortunate, as no one denomination of the imperial measure corresponds exactly with the same denomination of the wine measure; and the formulæ, therefore, of the London and Edinburgh Colleges, so far as measures are concerned, when they agree in terms with those of the United States and Dublin Pharmacopœias, differ from them in reality; while in other cases, though differing in terms, they may be quite or very nearly identical. It is very important that the apothecary should bear this distinction in mind; and, when he has occasion to carry into effect one of the London or Edinburgh formulæ, that he should make the due allowances. He will find, among the Tables in the Appendix of this work, a statement of the relative value of the several denominations of the imperial and wine measures, and by consulting this statement will be enabled to convert the former into the latter without difficulty. The measures kept in his shop should be graduated according to the divisions of the wine gallon; as this is recognised by our own official standard.

In the *Pharmacopœia of the United States*, and in those of the *Edinburgh* and *Dublin Colleges*, when the specific gravity of a body is given,

it is considered to be at the temperature of 60° of Fahrenheit; in the *London Pharmacopœia*, at 62°.

The *United States* and *London Pharmacopœias* explain the term *gentle heat* as signifying a temperature between 90° and 100°. The *Dublin College* employs the terms *superior*, *medium*, and *inferior heat*, the first signifying a temperature between 200° and 212°, the second between 100° and 200°, and the third between 90° and 100°. Fahrenheit's scale is referred to by all the official standards.

Maceration, according to the *Dublin College*, is performed at a temperature between 60° and 90°, *digestion* at their "*inferior heat*."

The *London College* directs that acid, alkaline, and metallic preparations, and salts of every kind, be kept in stopped glass bottles, which, for certain substances, should be of black or green glass; the *Dublin College*, that mortars, measures, funnels, and other vessels in which medicines are prepared, should be made of materials containing neither copper nor lead. Earthen vessels, therefore, glazed with lead, are improper.

Whenever, in the *United States* and *London Pharmacopœias*, an acid or an alkali is directed to be saturated, the point of saturation is to be ascertained by means of litmus or turmeric. For this purpose litmus or turmeric paper is usually employed, the latter being rendered brown by the alkalies, the former being reddened by the acids, and having its blue colour restored by the alkalies. (See *Lacmus* and *Curcuma*.) The *London College* directs that, unless otherwise ordered, bibulous paper should be used both for filtering liquors and drying crystals.

Filtration by displacement, or *Percolation*. In relation to this process, the following directions are given in the *United States Pharmacopœia*. "The kind of filtration commonly called *displacement*, which is employed in many of the processes of this Pharmacopœia, is to be effected in the following manner, unless otherwise specially directed. A hollow cylindrical instrument is to be used, somewhat conical towards the inferior extremity, having a funnel-shaped termination so as to admit of being inserted into the mouth of a bottle, and provided internally, near the lower end, with a transverse partition or diaphragm pierced with numerous minute holes, or, in the absence of such a partition, obstructed with some insoluble and inert substance, in such a manner that a liquid poured into the cylinder may percolate slowly. (See page 763.) The substance to be acted upon, having been reduced to a coarse powder, and mixed with enough of the menstruum to moisten it thoroughly, is, after a maceration of some hours, to be introduced into the instrument, and slightly compressed upon the diaphragm. Any portion of the macerating liquid which may not have been absorbed by the powder, is afterwards to be poured upon the mass in the instrument, and allowed to percolate. Sufficient of the menstruum is then to be gradually added to drive before it, or displace, the liquid contained in the mass; the portion introduced is in like manner to be displaced by another portion; and so on till the required quantity of filtered liquor is obtained. If the liquor which first passes should be turbid, it is to be again introduced into the instrument. Care must be taken that the powder be not, on the one hand, too coarse or loosely pressed, lest it should allow the liquid to pass too quickly, nor, on the other, too fine or compact, lest it should offer an unnecessary resistance. Should the liquor flow too rapidly, it is to be returned to the instrument, which is then to be closed beneath for a time, in order that the finer parts of the powder may subside, and thus cause a slower percolation."

The *Edinburgh College* gives directions for percolation under the head of 'Tinctures. According to that College, "the solid materials, usually in coarse or moderately fine powder, are moistened with a sufficiency of the solvent to form a thick pulp; in twelve hours, or frequently without any delay, the mass is put into a cylinder of glass, porcelain, or tinned iron, open at both ends, but obstructed at the lower end by a piece of calico or linen, tied tightly over it as a filter (*see figure in the margin*); and the pulp being packed by pressure, varying as to degree with various articles, the remainder of the solvent is poured into the upper part of the cylinder, and allowed gradually to percolate. In order to obtain the portion of the fluid which is kept in the residuum, an additional quantity of the solvent is poured into the cylinder, until the tincture which has passed through, equals in amount the spirit originally prescribed."

The advantages of the process of percolation or displacement are, that the active soluble principles of medicinal substances, are in general extracted by it more speedily, thoroughly, and economically than by any other mode; that concentrated solutions of these principles are more easily obtained; and that no portion of the impregnated menstruum need be lost by remaining in the solid mass. It is, however, liable to the objection that considerable experience and skill are necessary to carry it properly into effect, and that, if improperly performed, it must often result in preparations very different from those contemplated in the formulæ. It should not, therefore, be resorted to in the fulfilment of official directions, when any alternative is given, unless by individuals who have acquired the requisite skill by much practice. Hence, both the United States and *Edinburgh Pharmacopœias*, when directing displacement in any particular case, frequently give another mode of accomplishing the same object, better adapted to inexperience in the operator.

The sources of failure in this process are chiefly an improper degree of comminution in the substance to be acted upon, and an improper condition of the mass after it has been introduced into the instrument. If the material be in too fine a powder, it resists or obstructs the passage of the fluid; if too coarse, it allows the fluid to pass too rapidly, and at the same time opposes its cohesion to the solvent power of the menstruum. If merely bruised, especially, if fibrous pieces of some length are intermixed, it causes the fluid to make irregular channels and thus to act upon it partially. An improper packing of the material occasions similar inconveniences. If too compact it impedes, if too loose it injuriously facilitates the passage of the solvent, and if not uniform, it produces an irregular flow which necessarily vitiates the result. The liquid, finding an easier passage at one part than another, flows more rapidly in that direction, and thus makes channels by which it may in great measure or wholly escape, with little influence upon the mass. Besides, the uniform progression by which each superadded portion displaces that immediately beneath it is broken, the successive layers become intermingled, and thus one of the peculiar advantages of the process is lost. The following observations may be of some use in assisting the operator to avoid these consequences.

The solid material should in general be in the state of a uniform coarse powder, to which it is most conveniently brought by grinding in a common coffee-mill. If its texture, however, be very hard, firm, and not easily permeable by moisture, as in certain barks, woods, and ligneous roots, it should be rather finely powdered. If, on the contrary, the texture be loose

and spongy, and especially if the material be disposed to swell up and form a viscid mass with water, so as to impede percolation, as in the case of gentian and squill, it may be advisable merely to bruise it in a mortar; though care should be taken to do this as equably as possible; and the substances which require this treatment when water is used, may come under the general rule with another solvent, as alcohol or ether.

It is generally advisable, before introducing the material into the instrument, to mix it with a portion of the solvent, and allow it to stand for some time in another vessel. It thus becomes more penetrable and more easily acted on by the menstruum, admits of a more uniform packing, and, if liable to swell with water, undergoes this expansion where it cannot have the effect of checking percolation. The quantity of liquid should be sufficient to form a soft pulp-like mass with the powder. In general, a weight about half that of the solid material will be sufficient, though a much larger quantity may be used if on any account deemed advisable. The maceration may continue on the average about twelve hours; but a much shorter time will often answer. It has sometimes been recommended to perform this preliminary maceration in the displacement filter, its lower orifice being closed for a time. With some substances this may be done without disadvantage, but in all those instances in which the material is liable to swell considerably with water, and thus to choke the passage, the maceration should take place in another vessel.

The packing of the material in the instrument is that part of the process which most requires experience in the operator, and about which the least precise rules can be given. When mixed with a considerable portion of fluid, it will often subside of itself into the proper state; but generally it requires some shaking or pressure, and the degree of the latter must be in proportion to the looseness of texture in the material; reference, however, being always had to its disposition to swell with water. Certain substances in which this property is found, such as gentian and rhubarb, must not be pressed compactly, when water is the solvent. As the percolation advances, and portions of the substance acted on are dissolved, the mass often becomes too loose, and requires to be again pressed down. Substances which are apt to form with the menstruum an adhesive and impermeable mass, such as the resins and gum-resins, may be advantageously mixed, in the state of coarse powder, with about half their weight of perfectly clean white sand, as suggested by Mr. Duhamel. (See *Am. Journ. of Pharm.* x. 15.) The sand separates the particles of the mass, and allows the menstruum a readier access.

After the moistened material has been properly packed, the upper surface should be made quite level, and then covered with a circular disk of tin or filtering paper pierced with numerous minute holes; and, if the disk be of paper, it should be kept in its place by pieces of glass rod. The solvent is thus made to enter into the mass equably, and prevented from forming partial passages by bearing upon one or a few points. The liquid is now to be introduced in successive portions, as stated in the official directions above given, and in the general account of the process given at page 763.

The fluid which first passes is generally turbid. This should be returned into the instrument; and the same thing should be done with the portions which pass successively, until the liquid comes away perfectly clear. If the percolation be too rapid, pressure may be made upon the upper diaphragm so as to render the mass more compact, or the instrument may be closed below for a time, as stated in the official directions. Hence the advantage of having a stop-cock near the lower end for regulating the discharge. When the percolation is too slow it may be increased by the pressure of a

column of liquid, and this plan may sometimes be advantageously resorted to when the powder is very fine, or large masses of material are operated upon. (*See page 763.*) When the object is to keep up a constant supply of the percolating fluid, it may be accomplished by filling a long-necked bottle or matrass with the fluid, and inverting it over the filtering instrument, with its mouth beneath the surface of the liquid in the latter.

Hot liquids may be used in the process as well as cold, and are sometimes preferable when the substance yields its active principles more largely at an elevated temperature. But there is often an inconvenience in employing hot water; as it dissolves or renders glutinous substances not affected by cold water, which are not requisite, and may even be injurious in the preparation, and tend to embarrass the process, by filling up the interstices of the mass, and thus rendering it less permeable.

The first portion of filtered liquid is very strongly impregnated, and the portions which subsequently come away, are successively less so. It is sometimes desirable to obtain the whole of the particular solvent employed. This end may be very nearly attained by adding, at the close of the process, enough of another liquid to supply the place of that retained in the mass. It was Boullay's idea that the whole of the liquid contained in the moist material might be thus driven out of it or displaced by the one added, without any admixture of the two. This, however, has been ascertained not to be exactly true; and, however carefully the process may be conducted, some mixture will take place. Hence it is recommended, when one liquid is added in order to displace another, to introduce first a shallow layer of the same liquid with that contained in the mass. In some instances, the solvent, if consisting of two liquids, is resolved into these in the process. Thus when myrrh is subjected to percolation with proof spirit, the first liquid which comes away is anhydrous alcohol holding the oil and resin of the myrrh in solution.

There are very few substances to which the mode of filtration by displacement will not be found applicable, if due attention be paid to the circumstances which require variations in the process.

Distillation. In the preface to the last edition of the *Edinburgh Pharmacopæia*, the following remarks are made in relation to this process. "In the process of distillation, complete success cannot be easily attained, especially on the small scale, without the substitution of a different apparatus for the retort and receiver commonly used. In all operations, except where inorganic acids are to be distilled, it is greatly preferable to use a globular

matrass (*a*), to which is fitted with a cork a tube (*bc*) cut obliquely at its lower end (*b*), curved above at a somewhat acute angle, and fitted at the other end to a refrigeratory. This refrigeratory consists of a long narrow

cylinder (*df*) slightly inclined to the horizon, and of a tube (*ce*) which passes along the centre of the cylinder, and is fixed at each end, so that the space between them is air-tight; and by means of a funnel (*gh*) entering at the lower end of this interspace, and an exit tube (*di*) from its upper extremity, a stream of cold water may be kept constantly running, by which refrigeration and the condensation of vapours within the inner tube are far more effectually accomplished than by any other mode that has hitherto been devised." The object of the oblique ending of the tube at *b*, is to prevent any of the fluid which may be driven against it, during the ebullition, from passing along the tube. The inner tube of the refrigeratory should be made of glass or block-tin, the outer may consist of glass, brass, copper, or common tinned iron. The end *e* of the central tube is either straight, or curved downward so that it may be inserted into a bottle, when the liquid distilled is very volatile. By connecting the funnel with a cistern by means of a syphon, and allowing the water to flow out from the bent tube *di* into a bucket or sink, the distillation may be allowed to go on for a long time without supervision. Dr. Christison states that a refrigeratory with the outer tube a foot long, and an inch and a quarter in diameter, will be sufficient to condense the whole vapour from a matrass holding two pints of alcohol briskly boiling.

W.

ACETA.

Vinegars.

Under this title, in the United States Pharmacopœia, are included both Distilled Vinegar and those preparations usually denominated *Medicated Vinegars*. The latter are infusions or solutions of various medicinal substances in vinegar or acetic acid. The advantage of vinegar as a menstruum is that, in consequence of the acetic acid which it contains, it will dissolve substances not readily soluble or altogether insoluble in water alone. It is an excellent solvent of the vegetable alkalies, which it converts into acetates, thereby modifying in some measure, though not injuriously, the action of the medicines of which they are ingredients. As ordinary vinegar contains principles which promote its decomposition, it should be purified by distillation before being used as a solvent. Infusions prepared with it, even in this state, are apt to spoil in a short time; and a portion of alcohol is usually added to contribute to their preservation. A small quantity of acetic ether is said to result from this addition; and, on the continent of Europe, the place of the alcohol is frequently supplied by an equal amount of concentrated acetic acid. In consequence of their liability to change, the medicated vinegars should be made in small quantities, and kept but for a short time.

W.

ACETUM DESTILLATUM. *U. S., Lond., Ed.;* ACETUM DISTILLATUM. *Dub. Distilled Vinegar.*

"Take of Vinegar a gallon. Distil the Vinegar, by means of a sand-bath, from a glass retort into a glass receiver. Discontinue the process when seven pints shall have been distilled, and keep these for use." *U. S.*

The *London* process is the same as that of the *U. S. Pharmacopœia*. The *Edinburgh* process is as follows. "Take of Vinegar (French by preference) eight parts: distil over with a gentle heat, seven parts: dilute the product, if necessary, with distilled water till the density is 1.005." The *Dublin* College distils wine vinegar. The first tenth which comes

over is rejected, the next seven-tenths are the "distilled vinegar," having the sp. gr. 1·005, and two-tenths are left behind in the retort.

Vinegar is a very heterogeneous liquid, containing colouring matter, gum, sugar, alcohol, &c.; and the object of its distillation is to purify it. (See *Acetum*.) The first portion which distils contains alcohol and pyroacetic spirit (acetone), these being the most volatile ingredients; next the acetic acid comes over much purified, but weaker than it exists in the vinegar, on account of its being less volatile than water; and if the distillation be stopped when the pure vinegar ceases to come over, there will be found in the retort a liquid of a deep brown colour, very sour and empyreumatic, and containing free tartaric and malic acids, bitartrate of potassa, and other substances. This statement explains why the last portion is not distilled. The proportion preserved is seven-eighths according to the U. S., London, and Edinburgh Pharmacopœias, and seven-tenths according to the Dublin. The residuary liquid in the retort, if diluted with an equal bulk of hot water, may be made to yield, by a fresh distillation, a quantity of weak acetic acid, equal to the residuary liquid, and of about the strength and purity of official distilled vinegar.

Wine vinegar furnishes a stronger distilled vinegar than malt or cider vinegar. The Dublin College gives 1·005 as the density of distilled vinegar; but the product of different vinegars is by no means necessarily of the same strength or density. The Edinburgh College, assuming that distilled vinegar will have the sp. gr. of at least 1·005, directs that its density, when above that number, shall be reduced to it. When brought to this standard, the College states that 100 minims of it neutralize 8 grains of carbonate of soda. In the U. S. and London Pharmacopœias, the strength of distilled vinegar is indicated exclusively by its saturating power. According to our national standard, a fluidounce (455 grains) is saturated by about 35 grains of the crystals of bicarbonate of potassa; and by the London College 100 grains of it are stated to be saturated by 13 grains of the crystals of carbonate of soda. The saturating power of the different official distilled vinegars indicates the following proportions of dry acetic acid per cent;—*U. S. Pharmacopœia* 3·9, *London* 4·6, *Edinburgh* 3·07. Considering the ordinary pharmaceutical uses of distilled vinegar, variations in its strength, limited as they are by the qualities of different vinegars, are not important. Its purity is the point of importance. If, however, precision be attempted, the saturating power and not the density must be indicated; and directions should be given for bringing a distilled vinegar which varies from the standard of saturating power, to that standard by the addition either of pure acetic acid, or of distilled water. The reason why density cannot be depended upon, is that the specific gravity is not in proportion to the strength. If the vinegar contain a good deal of alcohol and pyroacetic spirit, the distilled product will be light, but not necessarily weak. This remark applies particularly to distilled wine vinegar. The Dublin College removes in part the ambiguity of density as an indication of strength, by rejecting the first tenth which distils over; but by this rejection, the more agreeable and aromatic part of the vinegar is lost.

The different Pharmacopœias, except the Edinburgh, direct the distillation of vinegar to be conducted in glass vessels; but it is generally distilled in a copper alembic furnished with a pewter worm as a refrigerator. The use of these metals, however, is hazardous, on account of the danger of metallic impregnation. Mr. Brande has suggested that the refrigerator might be made of very thin silver, a metal not acted on by acetic acid of any strength. If this cannot be procured, the head and worm should be of

glass or earthenware. Empyreuma is effectually prevented by distilling by means of steam.

Properties. Distilled vinegar is a limpid, colourless liquid, of a weak acetous taste and smell, less agreeable than those of common vinegar. It is wholly volatilized by heat. It is not a perfectly pure solution of acetic acid in water; but contains a portion of organic matter which rises in the distillation. It is on account of the partial decomposition of this impurity, that distilled vinegar, when saturated with an alkali, is liable to become of a reddish or brownish colour. When distilled in metallic vessels, it is apt to contain traces of copper, lead, and tin. Copper is detected, after saturating with ammonia, by the addition of ferrocyanuret of potassium, which produces a brown cloud; lead by iodide of potassium, which occasions a yellow precipitate; and tin by a solution of chloride of gold, which causes a purplish appearance. The two latter metals are discovered also by sulphuretted hydrogen, which occasions a dark-coloured precipitate. The non-action of this gas proves the absence of metals generally. Distilled vinegar should not have an empyreumatic taste nor a sulphurous smell. As usually prepared, however, it is somewhat empyreumatic. Malt vinegar contains a small proportion of sulphuric acid; but when it is distilled, this acid does not come over. If, however, sulphuric acid should be accidentally present in distilled vinegar, it may be detected by chloride of barium or acetate of lead. If muriatic acid be present, it may be shown by a precipitate being formed with nitrate of silver; and if nitric acid be an impurity, the vinegar will possess the property, by digestion, of dissolving silver, which may be detected afterwards by muriatic acid.

Medical Properties and Uses. The medical properties of distilled vinegar are the same as those of common vinegar (See *Acetum*); but the former being purer, and not liable to spontaneous decomposition, is preferable for pharmaceutical purposes. It is employed as the basis, with but few exceptions, of the two classes of preparations called "Vinegars" and "Oxymels."

Off. Prep. Emplastrum Ammoniaci, *Lond., Ed.*; Hydrargyri Acetas, *Dub.*; Liquor Ammoniae Acetatis, *Lond., Ed., Dub.*; Oxymel, *Dub.*; Plumbi Acetas, *Dub.*; Plumbi Subacetatis Liquor, *Dub.*; Potassæ Acetas, *Dub.*; Sodæ Acetas, *Dub.*; Syrupus Allii, *U.S.*; Unguentum Plumbi Compositum, *Lond.* B.

ACETUM CANTHARIDIS. (*Epispasticum.*) *Lond.* ACETUM CANTHARIDIS, *Ed.* *Vinegar of Spanish Flies.*

"Take of Spanish Flies, in powder, *two ounces*; Acetic Acid *a pint* (Imperial measure). Macerate the Spanish Flies with the Acid for eight days, occasionally shaking. Finally express and filter." *Lond.*

"Take of Cantharides, in powder, *three ounces*; Acetic Acid *five fluid-ounces*; Pyroligneous Acid *fifteen fluidounces*; Euphorbium, in coarse powder, *half an ounce*. Mix the acids, add the powders, macerate for seven days, strain and express strongly, and filter the liquor." *Ed.*

This preparation is intended exclusively for external use, as a speedy epispastic. It is said, when lightly applied by a brush, to act as a rubefacient; and when rubbed freely upon the skin for three minutes, to be followed, in two or three hours, by full vesication. The pain produced by the application, though more severe, is also more transient than that which results from the blistering cerate. From experiments made by Mr. Redwood, it may be inferred that the preparation proves epispastic chiefly if not exclusively in consequence of its acetic acid, and that it contains little of the active principle of the flies. (*Lond. Pharm. Transact. Oct. 1841.*)

ACETUM COLCHICI. *U.S., Lond., Ed., Dub. Vinegar of Colchicum.*

“Take of [dried] Colchicum Root, bruised, *two ounces*; Distilled Vinegar *two pints*; Alcohol *a fluidounce*. Macerate the Colchicum Root with the Distilled Vinegar, in a close glass vessel, for seven days; then express the liquor, and set it by that the dregs may subside; lastly, pour off the clear liquor, and add the Alcohol.

“Vinegar of Colchicum may also be prepared by macerating the Colchicum Root, in coarse powder, with a pint of Distilled Vinegar for two days, then putting the mixture into an apparatus for displacement, gradually pouring in Distilled Vinegar until the quantity of filtered liquor equals two pints, and lastly adding the Alcohol.

“In the above processes, Diluted Acetic Acid may be substituted for Distilled Vinegar.” *U. S.*

The *London* and *Edinburgh Colleges* direct an ounce of the fresh bulb, sixteen fluidounces of distilled vinegar, and a fluidounce of proof spirit; the *Dublin College*, an ounce of the fresh bulb, a pint of distilled vinegar, and a fluidounce of proof spirit; all macerate for three days, and proceed as directed in the first process of the *U. S. Pharmacopœia*, except that the *Edinburgh College* filters the expressed liquid, instead of clarifying it by rest and decantation. The resulting preparations may be considered as identical with each other, and with the American; as the dried bulb of our shops is probably not on an average much stronger than the fresh bulb in Europe, and the proof spirit of the *British Colleges* is equivalent to little more than half its bulk of our official alcohol.

Vinegar is an excellent solvent of the active principle of colchicum; and the organic alkali of the latter loses none of its efficacy by combination with the acetic acid of the former. The use of the alcohol is simply to retard the spontaneous decomposition to which this, like most of the other medicated vinegars, is liable.

Medical Uses. This preparation has been extolled as a diuretic in dropsy; and may be given in gout, rheumatism, and neuralgia; but the wines of colchicum are usually preferred. It is recommended by Scudamore to be given in connexion with magnesia, so as to neutralize the acetic acid of the menstruum. The dose is from thirty drops to two fluidrachms. *W.*

ACETUM OPII. *U.S., Ed., Dub. Vinegar of Opium. Black Drop.*

“Take of Opium, in coarse powder, *eight ounces*; Nutmeg, in coarse powder, *an ounce and a half*; Saffron *half an ounce*; Sugar *twelve ounces*; Distilled vinegar *a sufficient quantity*. Digest the Opium, Nutmeg, and Saffron with a pint and a half of Distilled Vinegar, on a sand-bath, with a gentle heat, for forty-eight hours, and strain. Digest the residue with an equal quantity of Distilled Vinegar, in the same manner, for twenty-four hours. Then put the whole into an apparatus for displacement, and return the filtered liquor, as it passes, until it comes away quite clear. When the filtration shall have ceased, pour Distilled Vinegar gradually upon the materials remaining in the instrument, until the whole quantity of filtered liquor equals three pints. Lastly, add the Sugar, and, by means of a water-bath, evaporate to three pints and four fluidounces.

“In the above process, Diluted Acetic Acid may be substituted for Distilled Vinegar.” *U. S.*

“Take of Opium *four ounces*; Distilled Vinegar *sixteen fluidounces*. Cut the Opium into small fragments, triturate it into a pulp with a little of the Vinegar, add the rest of the Vinegar, macerate in a closed vessel for seven

days, and agitate occasionally. Then strain and express strongly, and filter the liquor." *Ed.*

The Dublin process is essentially the same as the Edinburgh, which was adopted from it.

The vinegar of opium has been introduced into the Pharmacopœias as an imitation of, or substitute for a preparation which has been long in use under the name of *Lancaster* or *Quaker's black drop*, or simply *black drop*. The formula of the first edition of the U. S. Pharmacopœia was so deficient in precision, and consequently so uncertain in its results, that it was abandoned in the second edition; but, as this objection was obviated in a process by Mr. Charles Ellis published in the American Journal of Pharmacy (vol. ii. page 202), and as the preparation continued to enjoy a considerable degree of professional and popular favour, it was deemed proper to restore it to its officinal rank at the last revision of the Pharmacopœia. The U. S. formula above given is essentially that of Mr. Ellis. It is, we think, preferable to the Edinburgh and Dublin formula. In the latter we cannot but suspect that there is some waste of opium; as Dr. Montgomery, in his observations on the Dublin Pharmacopœia, states that twenty drops are equivalent to thirty of the common tincture of opium, though, in the preparation of the latter, somewhat less than one-third the quantity of opium is used. As common distilled vinegar is often very weak, it would be best to employ white wine vinegar, as directed by Mr. Ellis. The chief advantage of the black drop over laudanum is, probably, that the meconate of morphia is converted by the acetic acid into the acetate; though this has not been positively proved. In the original process published by Dr. Armstrong, who found it among the papers of a relative of the proprietor in England, *verjuice*, or the juice of the wild crab, was employed instead of vinegar. Other vegetable acids also favourably modify the narcotic operation of opium; and lemon juice has been employed in a similar manner with vinegar or *verjuice*, and perhaps not less advantageously.*

The vinegar of opium may sometimes be advantageously used when opium itself, or the tincture, in consequence of peculiarity in the disease or in the constitution of the patient, occasions so much headache, nausea, or nervous disorder, as to render its employment inconvenient if not impossible. It exhibits all the anodyne and soporific properties of the narcotic, with less tendency to produce these disagreeable effects, at least in many instances. It is of about double the strength of laudanum, six and a half minims containing the soluble parts of about one grain of opium, supposing the drug to be completely exhausted by the menstruum. The dose may be stated at from seven to ten drops or minims. W.

ACETUM SCILLÆ. U. S., Lond., Ed., Dub. *Vinegar of Squill.*

"Take of Squill, bruised, *four ounces*; Distilled Vinegar *two pints*; Alcohol *a fluidounce*. Macerate the Squill with the Distilled Vinegar, in a close

* The following is the formula given in the first edition of the U. S. Pharmacopœia. "Take of Opium *half a pound*; Vinegar *three pints*; Nutmeg, bruised, *one ounce and a half*; Saffron *half an ounce*. Boil them to a proper consistence; then add Sugar *four ounces*; Yeast *one fluidounce*. Digest for seven weeks, then place in the open air until it becomes a syrup; lastly, decant, filter, and bottle it up, adding a little sugar to each bottle." The boiling to a *proper consistence*, the digestion in the open air *until a syrup is formed*, and the addition of a *little sugar* to each bottle, are all indefinite directions, which must lead to uncertain results. Independently of this want of precision, the point in which the old process chiefly differs from that at present officinal, is that in the former fermentation is induced by the addition of yeast. But fermentation is of very doubtful value in the process; at least its advantages have not been proved.

glass vessel, for seven days; then express the liquor, and set it by that the dregs may subside; lastly, pour off the clear liquid, and add the Alcohol.

“Vinegar of Squill may also be prepared by macerating the Squill, in coarse powder, with a pint of Distilled Vinegar for two days, then putting the mixture into an apparatus for displacement, gradually pouring in Distilled Vinegar until the quantity of filtered liquor equals two pints, and lastly adding the alcohol.

“In the above processes, Diluted Acetic Acid may be substituted for Distilled Vinegar.” *U. S.*

The *London College* directs *fifteen ounces* of recently dried squill, *six pints* (Imperial measure) of distilled vinegar, *half a pint* (Imp. meas.) of proof spirit, and maceration with a gentle heat for twenty-four hours. The *Edinburgh College* directs *five ounces* of dried squill, *two pints* (Imp. meas.) of distilled vinegar, *three fluidounces* of proof spirit, and maceration for seven days. The *Dublin College* takes *half a pound* of recently dried squill, *three pints* of distilled vinegar, and *four fluidounces* of rectified spirit; and macerates for seven days.

In the United States process by displacement, the whole of the vinegar employed in the maceration, and introduced with the squill into the instrument, should be allowed to enter the mass, before the fresh portion of vinegar is added. The preparations of the several Pharmacopœias are so nearly the same that, for all practical purposes, they may be considered identical. The proportion of alcohol is rather less in the United States formula, than in either of the others. In the formula of the French Codex there is none; but the vinegar is stronger than ours. The only object of the alcohol is to retard the decomposition of the vinegar of squill; while its presence is medically injurious by rendering the preparation too stimulating. It is best, therefore, to prepare the vinegar of squill frequently, and in small quantities, so as to require little alcohol for its preservation. In the preparation of the oxymel and syrup of squill, for which purpose the vinegar is chiefly used in this country, it should be employed without alcohol. The vinegar of squill deposits, upon standing, a precipitate which consists, according to Vogel, of citrate of lime and tannic acid.

Medical Uses. This preparation has all the properties of the squill in substance, and is occasionally prescribed as a diuretic and expectorant in various forms of dropsy and of pulmonary disease; but the oxymel and syrup are usually preferred, as they keep better and are less unpleasant to the taste. The dose is from thirty minims to two fluidrachms; but the latter quantity would be apt to produce vomiting. It should be given in cinnamon-water, mint-water, or some other aromatic liquid calculated to conceal its taste and obviate its nauseating effect.

ACIDUM ACETICUM CAMPHORATUM. *Ed.*, *Dub.* *Camphorated Acetic Acid.*

“Take of Acetic Acid *six fluidounces* [*six fluidounces and a half, Ed.*]; Camphor *half an ounce*; Rectified Spirit *a sufficient quantity*. Reduce the camphor to powder by means of the spirit; then add the acid, and dissolve.” *Dub.*

The use of the alcohol is simply to facilitate the pulverization of the camphor, and a few drops are sufficient. Acetic acid in its concentrated state readily dissolves camphor. In this preparation, the whole of the camphor is taken up by the acid. In consequence of the powerful chemical

agency of the solution, and its extreme volatility, it should be kept in glass bottles accurately fitted with ground stoppers.

Camphorated acetic acid is an exceedingly pungent perfume, which, when snuffed up the nostrils, produces a strongly excitant impression, and may be beneficially resorted to in cases of fainting or nervous debility. It is an officinal substitute for Henry's *aromatic spirit of vinegar*.

At Apothecaries' Hall, in London, an *Aromatic vinegar* is prepared by dissolving the oils of cloves, lavender, rosemary, and calamus, in highly concentrated acetic acid. It is used for the same purpose as the officinal camphorated acetic acid, being dropped on sponge and kept in smelling bottles. A similar preparation may be made extemporaneously by adding to a drachm of acetate of potassa contained in a stoppered bottle, three drops of one or more of the aromatic volatile oils, and twenty drops of sulphuric acid. (*Pereira's Mat. Med.*)

A preparation called *Marseilles vinegar*, or *thieves' vinegar* (*vinaigre des quatre voleurs*), consisting essentially of vinegar impregnated with aromatic substances, was formerly esteemed a prophylactic against the plague and other contagious diseases. It is said to have derived its name and reputation from the circumstance, that four thieves, who, during the plague at Marseilles, had plundered the dead bodies with impunity, confessed, upon the condition of a pardon, that they owed their safety to the use of it. The *aromatic acetic acid* of the former Edinburgh Pharmacopœia was intended as a simplification of this nostrum. It was made by macerating for a week an ounce of rosemary, an ounce of sage, half an ounce of lavender, and half a drachm of cloves, with two pounds of distilled vinegar, then expressing the liquor and filtering. Origanum was afterwards substituted for sage, and thirty fluidounces of acetic acid for the two pounds of distilled vinegar. In the last edition of the Pharmacopœia the preparation has been abandoned. In the present state of knowledge, it is hardly necessary to observe, that neither the original nostrum, nor its substitute, has any other power of protecting the system against disease, than such as may depend on its slightly stimulant properties, and its influence over the imagination.

W.

ACIDA.

Acids.

Acids, in chemical classification, are those compounds which are capable of uniting in definite proportions with alkalies, earths, and metallic oxides, with the effect of producing a combination, in which the properties of its constituents are mutually destroyed. Such combinations are said to be neutral, and are denominated salts. Most acids have a sour taste, and possess the power of changing vegetable blues to red; and, though these properties are by no means constant, yet they afford a ready means of detecting acids, applicable in practice to most cases. The above explanation of the nature of an acid is that usually given; but, according to strict definition, acids are compounds having a strong electro-negative energy, and, therefore, possessing a powerful affinity for electro-positive compounds, such as alkalies, earths, and metallic oxides. It is this antagonism in the electrical condition of these two great classes of chemical compounds that gives rise to their mutual affinity, which is so much the stronger, as their contrast in this respect is greater. In the majority of cases, the electro-negative compound or acid is an oxidized body, but by no means necessarily so. When it does not contain oxygen, this element is usually replaced by hydrogen.

These peculiarities in composition have given rise to the division of acids by some writers into *oxacids* and *hydracids*. *Vegetable acids*, for the most part, contain both oxygen and hydrogen.

A small number only of the acids are used in medicine; but among these are to be found examples of the three kinds above mentioned. B.

ACIDUM ACETICUM. *U. S., Lond., Ed., Dub. Acetic Acid.*

"Take of Acetate of Soda, in powder, *a pound*; Sulphuric Acid *half a pound*; Red Oxide of Lead *a drachm*. Pour the Sulphuric Acid into a glass retort, and gradually add the Acetate of Soda; then, by means of a sand-bath, distil with a moderate heat, into a glass receiver, till the residuum becomes dry. Mix the resulting liquid with the Red Oxide of Lead, and again distil, with a moderate heat, to dryness." *U. S.* The sp. gr. of this acid is 1.06, and 100 grains of it saturate 83.5 grains of crystallized bicarbonate of potassa.

"Take of Acetate of Soda *two pounds*; Sulphuric Acid *nine ounces*; Distilled Water *nine fluidounces* [Imperial measure]. Add the Sulphuric Acid, first mixed with the Water, to the Acetate of Soda put into a glass retort; then let the acid distil from a sand-bath. Care is to be taken that the heat be not too great towards the end." *Lond.* The specific gravity of this acid is 1.048, and 100 grains of it saturate 87 grains of crystallized carbonate of soda.

"Take of Acetate of Potassa *one hundred parts*; Sulphuric Acid *fifty-two parts*. Put the acid into a tubulated retort, and, at different intervals of time, add the Acetate of Potassa, waiting after each addition until the mixture becomes cool. Lastly, with a moderate heat, distil the acid until the residuum is dry. The specific gravity of this acid is 1.074." *Dub.*

"Take of Acetate of Lead *any convenient quantity*; heat it gradually in a porcelain basin, by means of a bath of oil or fusible metal (8 tin, 4 lead, 3 bismuth), to 320° F.; and stir till the fused mass concretes again: pulverize this when cold, and heat the powder again to 320°, with frequent stirring, till the particles cease to accrete. Add *six ounces* of the powder to *nine fluidrachms and a half* of Pure Sulphuric Acid, contained in a glass matrass; attach a proper tube and refrigeratory, and distil from a fusible metal bath with a heat of 320° to complete dryness. Agitate the distilled liquid with *a few grains* of Red Oxide of Lead to remove a little sulphurous acid, allow the vessel to rest a few minutes, pour off the clear liquor and redistil it. The density is commonly from 1.063 to 1.065, but must not exceed 1.0685." *Ed.*

These processes are intended to furnish a strong acetic acid. The *United States*, *London*, and *Dublin* formulæ are similar, consisting in the decomposition of the acetate of soda or of potassa by sulphuric acid. A sulphate of the alkali is formed, and the disengaged acetic acid distils over. The acetate of soda, however, is on several accounts the best salt for decomposition. Its advantages are, its uniform composition in the crystallized state, its giving rise to a residuary salt (sulphate of soda) easily washed out of the retort, and the abundance in which it can be obtained from the manufacturers of pyroligneous acid. (See *Sodæ Acetas*.) On the other hand, acetate of potassa is a deliquescent salt, and, therefore, liable to contain a variable quantity of water, and to yield an acid of variable strength. Besides, the residue of the process (sulphate of potassa) is not so easily removed from the retort. In either process, the acetic acid is apt to pass over contaminated with a small quantity of sulphurous acid, which, however, may be removed by a redistillation from a little red oxide of lead, as is directed in the *U. S.* process. In the *Edinburgh* process, acetate of lead is first freed from water of

crystallization by heat, and then distilled with sulphuric acid which combines with the protoxide of lead, and sets free the acetic acid which distils over. As a boiling temperature is not convenient for drying, nor sufficient for decomposing the acetate of lead, the requisite temperature is obtained by a bath of oil or fusible metal. The red oxide of lead removes the sulphurous acid by combining with it in such a way as, by a transfer of oxygen from the oxide to the acid, to form sulphate of protoxide of lead. This process, when carefully conducted, furnishes an acid of the maximum strength, consisting of one eq. of dry acid, and one of water.

Before proceeding to compare the different officinal acetic acids as to density, it is necessary to explain the nomenclature adopted in the several Pharmacopœias, which is somewhat confused. All these acids may be arranged in three divisions, according as their density is high, low, or intermediate. The following table presents a view of their names and densities.

ACETIC ACID.	<i>U.S.</i>	<i>Lond.</i>	<i>Ed.</i>	<i>Dub.</i>
Highest off. strength. }	_____	_____	Acidum Aceticum. Sp. gr. 1·063 to 1·065.	_____
Intermediate strength. }	Acidum Aceticum. Sp. gr. 1·06.	Acidum Aceticum. Sp. gr. 1·048.	Acidum Pyroligneum. Sp. gr. 1·034.	Acidum Aceticum. Sp. gr. 1·074.
Lowest do. }	Acidum Aceticum Dilutum.	_____	_____	_____

Thus it is perceived that the name "Acidum Aceticum" means in the Edinburgh Pharmacopœia the acid of maximum strength, and in the other Pharmacopœias, the acid diluted with water in various degrees. The strong acid was injudiciously adopted, as an officinal preparation, by the Edinburgh College. It is too powerful for convenient medicinal employment, and unnecessary in the formulas for camphorated acetic acid, vinegar of Spanish flies, and creasote mixture, the only ones in which it is employed by the College. Its density is given with great want of precision. This is stated to vary commonly from 1·063 to 1·065, but must not exceed 1·0685! In other words, the acid may vary in strength from purity to containing 3 per cent. of water. The intermediate acid varies in density, as seen by the table, according to the following numbers—1·074 *Dub.*, 1·06 *U.S.*, 1·048 *Lond.*, 1·034 *Ed.* Dr. Christison considers the name "Acidum Aceticum" as belonging only to the strongest acid, and objects to its application to the intermediate acid (injudiciously called pyroligneous acid by the Edinburgh College), because it contains water of dilution. It is impossible to attain entire precision in pharmaceutical nomenclature, and hence the simple name of an acid may be conventionally applied to it when not of full strength, just as the name "Acidum Hydrocyanicum" is applied to medicinal prussic acid by the Edinburgh College, without meaning the anhydrous acid. The weak acid (Acidum Aceticum Dilutum) is peculiar to the *U.S. Pharmacopœia*, and will be noticed in the next article.

The specific gravity of acetic acid increases with the strength up to the density of 1·0735 (maximum), after which it decreases until it reaches 1·0635, the density of the strongest acid. The following table, condensed

from one given by Pereira, on the authority of Mohr, as containing the most recent experiments, exhibits the sp. gr. of acetic acid of different strengths. The officinal and commercial acids are noted opposite to their several densities, and the corresponding number in the column on the left gives the percentage of *protohydrated* acid in each.

Per cent. of acid.	Specific Gravity.	Per cent. of acid.	Specific Gravity.
100	1·063	39	1·050 English pyroligneous acid.
99	1·065	37	1·048 Acetic acid, <i>Lond.</i>
97	1·068	32	1·042 } Scotch pyroligneous acid
90	1·073		} (strongest).
80	1·0735 Maximum density.	30	1·040
70	1·070	25	1·034 Pyroligneous acid, <i>Ed.</i>
60	1·067	20	1·027
54	1·063	10	1·015
50	1·060 Acetic acid, <i>U.S.</i>	5	1·006
40	1·051	4	1·005 Distilled vinegar, <i>Ed., Dub.</i>

The maximum density here given on the authority of Mohr (1·0735), is considerably lower than that fixed by Mollerat (1·079), and agrees best with the determination of Dr. T. Thomson (1·0713), which is still lower. Up to the specific gravity 1·062, the density of acetic acid is a pretty accurate index of strength; but above that specific gravity, two acids of different strengths may coincide in density. Thus, by the table, it is seen that an acid weighing 1·063 may be either the strongest possible liquid acid, or an acid containing only 54 per cent. of such acid. The ambiguity may be removed by diluting the acid with a portion of water, when, if the density be increased, the given specimen is the stronger acid of the two having the same density. A note referring to the Dublin acetic acid is excluded from the table, on account of its density being given at a higher number (1·074) than even the maximum of Mohr. The density of English and Scotch pyroligneous acid (*pure acetic acid from wood*) is given on the authority of Dr. Christison.

The process adopted in the French Codex for obtaining acetic acid, is the distillation to dryness of the acetate of copper (crystals of Venus). The distillation must be performed in a stoneware retort, and is described in detail by Thenard. The water of crystallization of the salt being evaporated before the acid begins to rise, there is a deficiency of the former liquid, necessary to hold the elements of the acetic acid together. Accordingly, a part of the acid is decomposed, being resolved into water, and a compound called *pyroacetic spirit* or *acetone*, which gives to the acid a peculiar fragrant smell. Pyroacetic spirit is a colourless, volatile, inflammable liquid, of a peculiar penetrating smell, and pungent taste like that of peppermint. Its sp. gr. is 0·7922 and boiling point 132°. It is miscible with water, alcohol, and ether in all proportions. Its formula is C_3H_3O .

Properties. The acetic acid of the United States, London and Dublin Pharmacopœias is a colourless, inflammable, volatile liquid, having an acrid taste, and fragrant, pungent smell. It unites in all proportions with water, and dissolves to a certain extent in alcohol. It is incompatible with the alkalis and alkaline earths, both pure and carbonated, with metallic oxides, and most substances acted on by other acids. It is wholly volatilized by heat, and yields no precipitate with chloride of barium or nitrate of silver.

The presence of copper, lead, or tin, may be detected by neutralizing the acid with ammonia, and testing successively with ferrocyanuret of potassium, iodide of potassium, and sulphuretted hydrogen, in the manner explained under *Acetum Destillatum*. This officinal acid consists of the strongest liquid acetic acid, diluted with a variable quantity of water. As is shown by the table just given, the *United States* acid contains 50 per cent. of water of dilution, and the *London*, 63 per cent. The dilution of the *Dublin* acid cannot be estimated from Mohr's table, but calculated from Mollérat's results, it contains $33\frac{1}{3}$ per cent. of water. The saturating strength of the *United States* and *London* acids is given under their respective formulas. The corresponding acid of the *Edinburgh* College, called *pyroligneous acid* by the College, is described at page 14.

Protohydrated acetic acid (*Acidum Aceticum*, Ed., *glacial acetic acid*, or *radical vinegar*) is a colourless, volatile, inflammable liquid, possessing a corrosive taste, and an acid, pungent, and refreshing smell. At the temperature of about 40° it becomes a crystalline solid. Its sp. gr. is 1.063. The anomaly of its having first an increasing and then a decreasing density upon dilution with water, has been already noticed. Acetic acid possesses the property of dissolving a number of substances, such as volatile oils, camphor, gluten, resins and gum-resins, fibrin, albumen, &c. As it attracts humidity from the atmosphere, it should be preserved in well-stopped bottles. Its combinations with salifiable bases are called acetates. It consists of one eq. of dry acid 51.48, and one of water $9=60.48$. The dry acid is composed of carbon, hydrogen, and oxygen, and its formula is $C_4H_3O_3$.

Medical Properties and Uses. Acetic acid acts as a stimulant and rubefacient. Owing to its volatility and pungency, its vapour is frequently applied to the nostrils as an excitant in syncope, asphyxia, and headache. When employed in this manner, it is generally added to a small portion of sulphate of potassa, so as to moisten the salt, and the mixture is put in small glass bottles with ground stoppers. The concentrated acid is only used externally, and acts as a rubefacient, vesicant, or caustic, according to the length of time it is applied. It is sometimes employed as a substitute for cantharides, where a speedy blister is desired; as, for example, in croup, sorethroat, and other cases of internal inflammation. It may be applied by means of blotting paper or cambric moistened with the acid. It is a good application to warts and corns, the vitality of which it frequently destroys. It is also a valuable remedy in scaldhead. The different officinal acetic acids are necessarily different in their medical applications. For producing a blister, the *Edinburgh* acid is unnecessarily strong, and the *London*, too weak.

B.

ACIDUM ACETICUM DILUTUM. *U. S. Diluted Acetic Acid.*

"Take of Acetic Acid *half a pint*; Distilled Water *five pints*. Mix them."

The acid resulting from the above formulæ is peculiar to the *United States Pharmacopœia*. The object of having this preparation, is to possess a weak solution of pure acetic acid, which may be substituted for distilled vinegar in all formulæ in which nicety is required. Distilled vinegar contains a

portion of organic matter, which is always darkened or precipitated when this acid is saturated with an alkali, an occurrence which does not take place when the diluted acetic acid of our Pharmacopœia is employed. As the *Acidum Aceticum* (U.S.) contains 50 per cent. of the strongest liquid acid, it is easy to determine by calculation that the *Diluted Acetic Acid* will contain 4.54 per cent. of the same acid. Fifteen parts by weight of the London acetic acid, mixed with eighty-five of water, will form an acid having, according to Mr. Phillips, the strength of distilled vinegar, and containing about 4.6 per cent. of dry acid.

Off. Prep. Liquor Ammoniaë Acetatis, U. S.

B.

ACIDUM BENZOICUM. U. S., Lond., Ed., Dub. Benzoic Acid.

“Take of Benzoin, in coarse powder, a pound. Put the Benzoin, previously thoroughly mixed with an equal weight of fine sand, into a suitable vessel, and, by means of a sand-bath, with a gradually increasing heat, sublime until vapours cease to rise. Deprive the sublimed matter of oil by pressure in bibulous paper, and again sublime.” U. S.

The London College proceeds exactly as above directed, except that it does not mix the benzoin with sand before subliming.

The Edinburgh College puts a convenient quantity of benzoin into a glass matrass, and completes the process in the same manner.

According to the Dublin process, five parts of benzoin, triturated with one part of fresh quicklime, are boiled in one hundred and thirty parts of water for half an hour, the mixture being constantly stirred with a rod. After having cooled, the clear liquor is decanted, and the residue is boiled with seventy parts of water, which is also decanted when cold. The liquors having been mixed are evaporated to one-half, and filtered through paper; and one part of muriatic acid is gradually added. The precipitate produced is separated from the supernatant liquid, washed with a small quantity of cold water, dried with a gentle heat, and submitted to sublimation in a proper apparatus.

Of the two processes above described, the first is most simple and easy. The acid, which exists in the benzoin combined with resin, is volatilized by the heat, and condensed in the upper part of the apparatus. Unless the temperature is very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid and gives it a brown colour, from which it cannot be entirely freed by bibulous paper; and this result sometimes takes place even with the greatest caution. The process for subliming benzoic acid is usually conducted in a glazed earthen vessel, surmounted by a cone of paper, or by another vessel with a small opening at top, and a band of paper pasted round the place of junction. After the heat has been applied for an hour, the process should be suspended till the condensed acid is removed from the upper vessel or paper cone, when it may be renewed, and the acid again removed, and thus alternately till coloured vapours rise. Mohr, after many experiments, recommends the following plan as unobjectionable. He considers the addition of sand useless, and even injurious by favouring the production of empyreumatic substances. In a round cast-iron pot, eight or nine inches in diameter and two inches deep, a pound or less of coarsely powdered benzoin is placed, and uniformly strewed over the bottom. The top of the pot is closed by a sheet of bibulous paper, which is secured to the sides by paste. A cylinder of thick paper in the form of a hat, just large enough to fit closely around the sides of the pot, is then placed over it, and in like manner secured by paste.

A moderate heat is now applied by means of a sand-bath, and continued for three or four hours. The vapours pass through the bibulous paper, which absorbs the empyreumatic oil, and are condensed in the inside of the hat in brilliant white flowers, having an agreeable odour of benzoin. (*Annal. der Pharm.* xxix. 178.) The remaining acid of the benzoin may be extracted, if deemed advisable, by treating the residue of the balsam with lime or carbonate of soda. From the mode of preparing benzoic acid by sublimation, it was formerly called *flowers of benzoin*.

By the Dublin process, the acid is extracted from the benzoin by combining it with a salifiable base, and is subsequently precipitated by an acid. It is purified by sublimation, which gives it the peculiar silky lustre which distinguishes it. The process of the Dublin College is essentially that of Scheele. Carbonate of soda may be substituted for the lime, and sulphuric for the muriatic acid employed by the Dublin College, and the precipitated benzoic acid may be purified by dissolving it in boiling water, which will deposit it upon cooling. This was formerly the process of the Edinburgh College. Both processes afford a purer product than that obtained by sublimation, but not preferable in a medicinal point of view; as the small quantity of oil present in the sublimed acid adds to its stimulant properties, and at the same time renders it pleasant to the smell.

Several other modes of extracting the acid have been recommended by different chemists. The following is the process of Stolze. One part of the balsam is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by carbonate of soda dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off; and the benzoate of soda contained in the residuary liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which lets fall the acid when it cools.

By the above process Stolze obtained 18 per cent. of acid from benzoin containing 19.425 per cent. By the process of Scheele (that of the Dublin College) he obtained 13.5 per cent.; by the agency of carbonate of soda, as in the former Edinburgh process, 12 per cent.; by sublimation only 7.6 per cent. Nevertheless, Mr. Brande says that the last process is on the whole the most economical. According to this author, good benzoin affords by sublimation from 10 to 15 per cent. of the acid contaminated with empyreumatic oil, and about 9 per cent. of the purified acid.

Properties. Sublimed benzoic acid is in white, soft, feathery crystals, of a silky lustre, and not pulverulent. From solution the acid crystallizes in transparent prisms. When quite pure it is inodorous; but prepared by sublimation from the balsam, it has a peculiar agreeable aromatic odour, dependent on the presence of an oil, which may be separated by dissolving the acid in alcohol, and precipitating it with water. Its taste is warm, acid, and acidulous. It is unalterable in the air, but at 230° melts, and at a somewhat higher temperature rises in suffocating vapours. It is inflammable, burning without residue. It is very sparingly soluble in cold, but is dissolved by about twenty-four parts of boiling water, which deposits it upon cooling. It is soluble in alcohol, and in concentrated sulphuric and nitric acids, from which it is precipitated by water. The fixed oils also dissolve it. It is entirely dissolved by solution of potassa, and precipitated from the solution by muriatic acid. Its solution reddens litmus paper, and it forms salts with salifiable bases; but its acid properties are not powerful. From the experiments of Wöhler and Liebig it may be inferred, that benzoic acid is composed of a peculiar hypothetical body, called *benzule*, and oxygen; and in the uncombined state it always contains water. Benzule consists of four-

teen equivalents of carbon 85.68, five of hydrogen 5, and two of oxygen 16=106.68. The crystallized acid contains one equiv. of benzole 106.68, one of oxygen 8, and one of water 9=123.68. It cannot be deprived of its water by heat, but sometimes loses it in combination. Benzoic acid is a characteristic constituent of the balsams, and has been found in various other vegetable, and some animal products.

Medical Properties and Uses. Benzoic acid is irritant to the mucous membrane, and stimulant to the system, and has been thought to be expectorant; but it is seldom used internally except as a constituent of one or two officinal preparations. It has recently been proposed by Dr. Alexander Ure as a remedy for uric acid depositions in the urine, and for the chalk-like concretions, consisting of urate of soda, in the joints of gouty individuals. It is supposed to operate by converting the uric into hippuric acid, and consequently the insoluble urates into soluble hippurates. Either benzoic acid or one of its salts may be employed for this purpose. A convenient mode is to give the acid with four parts of phosphate of soda, or one part and a half of biborate of soda, which enable it to be readily dissolved by water. The dose is from 10 to 30 grains. It is an ingredient in some cosmetic washes, and has been employed by way of fumigation as a remedy in affections of the skin.

ACIDUM HYDROCYANICUM. *U. S.*, *Ed.* ACIDUM HYDROCYANICUM DILUTUM. *Lond.* ACIDUM PRUSSICUM. *Dub.* *Hydrocyanic Acid.* *Prussic Acid.* *Cyanohydric Acid.*

“Take of Ferrocyanuret of Potassium *two ounces*; Sulphuric acid *an ounce and a half*; Distilled Water *a sufficient quantity*. Mix the acid with four fluidounces of distilled water, and pour the mixture, when cool, into a glass retort. To this add the Ferrocyanuret of Potassium, previously dissolved in ten fluidounces of Distilled Water. Pour eight fluidounces of Distilled Water into a cooled receiver, and, having attached this to the retort, distil, by means of a sand-bath, with a moderate heat, six fluidounces. Lastly, add to the product five fluidounces of Distilled Water, or as much as may be sufficient to render the Hydrocyanic Acid of such strength, that 12.7 grains of nitrate of silver, dissolved in distilled water, may be accurately saturated by 100 grains of the acid.

“Hydrocyanic Acid may be prepared, when wanted for immediate use, in the following manner.

“Take of Cyanuret of Silver *fifty grains and a half*; Muriatic Acid *forty-one grains*; Distilled Water *a fluidounce*. Mix the Muriatic Acid with the Distilled Water, add the Cyanuret of Silver, and shake the whole in a well-stopped vial. When the insoluble matter has subsided, pour off the clear liquor, and keep it for use. Hydrocyanic Acid should be kept in closely stopped bottles, from which the light is excluded.” *U. S.*

The processes of the *London College* for medicinal hydrocyanic acid, and for that extemporaneously obtained, are the same as those of the *U. S. Pharmacopœia*; the latter having been adopted from the former.

“Take of Ferrocyanide of Potassium *three ounces*; Sulphuric Acid *two fluidounces*; Water *sixteen fluidounces* [Imp. meas.]. Dissolve the salt in eleven fluidounces of the Water, and put the solution in a matrass with a little sand: add the acid, previously diluted with five fluidounces of the water and allowed to cool: connect the matrass with a proper refrigeratory: distil

with a gentle heat, by means of a sand-bath or naked gas flame, till fourteen fluidounces pass over, or till the residuum begins to froth up. Dilute the product with distilled water till it measures sixteen fluidounces." *Ed.*

"Take of Cyanuret [Bicyanuret] of Mercury *an ounce*; Muriatic Acid *seven fluidrachms*; Water *eight fluidounces*. From a glass retort, distil into a refrigerated receiver, eight fluidounces, to be kept in a well stopped bottle, in a cool and dark place. The specific gravity of this acid is 0.998." *Dub.*

Hydrocyanic acid was admitted as an officinal into the French Codex in 1818, into the first edition of the United States Pharmacopœia in 1820, into the Dublin Pharmacopœia in 1826, into the London in 1836, and into the Edinburgh in 1839. It is now made by two officinal processes, —from the ferrocyanuret of potassium in the U. S., London, and Edinburgh Pharmacopœias, and from the bicyanuret of mercury in the Dublin. It is also obtained by an extemporaneous process, when wanted for immediate use, in the U. S. and London Pharmacopœias, by decomposing the cyanuret of silver. When ferrocyanuret of potassium is decomposed by sulphuric acid, the residue in the retort is bisulphate of potassa, mixed with a compound of two eqs. of cyanuret of iron and one of cyanuret of potassium (*Everitt's salt*). Two eqs. of ferrocyanuret, $2(\text{FeCy} + 2\text{KCy})$, react with six eqs. of liquid sulphuric acid, $6(\text{SO}_3 + \text{HO})$, and produce three eqs. of hydrated bisulphate of potassa, $3(\text{KO}, 2\text{SO}_3 + \text{HO})$, together with one eq. of Everitt's salt, $2\text{FeCy} + \text{KCy}$, which remain in the retort, and three eqs. of hydrocyanic acid, 3HCy , which distil over. Everitt's salt, so named from its discoverer, called *biferrocyanuret of potassium* by Dr. Pereira, is yellow according to Mr. Everitt; but Dr. Pereira, who prepared it with the greatest care, always found it white. Its constitution ($2\text{FeCy} + \text{KCy}$) is precisely the converse of that of ferrocyanuret of potassium ($\text{FeCy} + 2\text{KCy}$).

The rationale of the U. S. and London process for obtaining hydrocyanic acid extemporaneously is exceedingly simple. The reacting materials are single equivalents respectively of cyanuret of silver and muriatic acid. These, by double decomposition, generate hydrocyanic acid which dissolves in the water, and chloride of silver which subsides, and from which the acid is poured off when clear. (See *Argenti Cyanuretum*.) As the cyanuret of silver is obtained from hydrocyanic acid, it seems, at first view, a useless procedure to expend the acid to make the cyanuret, with the intention of decomposing this afterwards to get the acid. But the extemporaneous process is useful to country practitioners; because the acid will not generally keep. A portion of hydrocyanic acid, if kept by a practitioner, may spoil on his hands, before he has occasion to use it; but if he supplies himself with a portion of cyanuret of silver, he may readily at any moment obtain a small portion of the acid, by following the directions of the formula.

The *Dublin* process is that of Gay-Lussac, with the use of a certain amount of water of dilution. Two equivalents of hydrogen from two equivalents of muriatic acid form two equivalents of hydrocyanic acid with the two equivalents of cyanogen in the bicyanuret of mercury, while the two equivalents of chlorine form one equivalent of bichloride of mercury, or corrosive sublimate, with the one equivalent of mercury. The Dublin College uses a little more than the equivalent quantity of muriatic acid, to ensure the complete decomposition of the bicyanuret.

The French Codex of 1837 gives the following process for hydrocyanic acid, in place of the three formerly contained in that work. Take of bicyanuret of mercury *thirty parts*; muriatic acid (sp. gr. 1.17) *twenty parts*. Re-

duce the bicianuret to powder, and introduce it into a small tubulated glass retort, placed over a furnace. Adapt to its neck a tube, about 13 inches long, and half an inch in diameter, and filled one-half with pieces of marble, and the remainder with chloride of calcium. To this tube, arranged nearly horizontally, adapt a smaller one, bent at a right angle, and plunging into a graduated tube, surrounded with a mixture of common salt and pounded ice. The apparatus being thus arranged, and the junctures well luted, add the muriatic acid; and, having allowed the action to take place for a few moments in the cold, apply the heat gradually and cautiously. When the action is over, drive forward any acid which may have condensed in the large tube, by means of a live coal brought near to it, and passed along its whole length. The quantity of acid found in the graduated tube is mixed with either six times its bulk, or eight and a half times its weight of distilled water. In case the acid is weighed, the operator must carefully avoid its deleterious vapours.

The above process is Gay-Lussac's, and, therefore, the same in principle as the Dublin. In the first part of it, Gay-Lussac's strong acid is obtained in the graduated tube, and this is afterwards diluted to a given extent with water. We have not found it stated what is the saturating strength of the Codex acid; but, from the method of preparation, we should suppose it to be much stronger than is safe for a medicinal acid. The object of the marble and chloride of calcium is to detain, the former muriatic acid, the latter water; so that it is probable that the acid in the graduated tube, if not anhydrous, is at least pretty strong.

Another process for obtaining medicinal hydrocyanic acid, proposed by Dr. Clarke, and adopted by Mr. Laming, is by the reaction of tartaric acid on cyanuret of potassium in solution. Mr. Laming's formula is as follows. Dissolve twenty-two grains of the cyanuret in six fluidrachms of distilled water, and add to this solution fifty grains of crystallized tartaric acid dissolved in three fluidrachms of rectified spirit. Crystallized bitartrate of potassa precipitates, and each fluidrachm of the clear decanted liquor contains one grain of pure hydrocyanic acid. (*Pereira, Elem. Mat. Med.*) The reaction in this process takes place between two equiv. of tartaric acid, one of cyanuret of potassium, and one of water. The water is decomposed, and the tartaric acid, potassium, and oxygen unite to form the bitartrate, and the cyanogen and hydrogen to form the hydrocyanic acid. Although Dr. Pereira considers this process to have several advantages, yet he very properly objects to it on account of the trouble and expense of obtaining the cyanuret pure, and its liability to undergo spontaneous decomposition. (See *Potassii Cyanuretum*.)

Liebig recommends the decomposition of cyanuret of potassium with liquid sulphuric acid. In this case the products of the double decomposition are sulphate of potassa and hydrocyanic acid. Any cyanate of potassa present as an impurity is at the same time decomposed, and the ammonia resulting from the cyanic acid unites with the sulphuric acid, so as to form a supersulphate. The mode of proceeding is to distil one part of the cyanuret dissolved in two parts of water, with one part of sulphuric acid, diluted with three parts of water. The hydrocyanic acid obtained is much stronger than the medicinal acid; but it may be reduced to any desired standard, by ascertaining its strength by nitrate of silver, and then adding the proper proportion of distilled water, as determined by an obvious calculation.

The processes, thus far given, are intended to furnish a *dilute* hydrocyanic acid for medicinal purposes. The methods of obtaining the *anhydrous* or *pure* acid are somewhat different. Vauquelin's process is to pass

a current of hydrosulphuric acid gas over the bicianuret of mercury contained in a glass tube, connected with a receiver kept cold by a freezing mixture of ice and salt. The first third only of the tube is filled with the bicianuret; the remaining two-thirds being occupied, half with carbonate of lead, and half with chloride of calcium. The hydrocyanic acid being generated in the first third of the tube, is driven forward by a gentle heat into the refrigerated receiver. By passing through the carbonate of lead and chloride of calcium, it is successively freed from any traces of hydrosulphuric acid or water. Gay-Lussac's process for the anhydrous acid is essentially the same as that by which the strong acid is procured in the graduated tube, in the French Codex process. (See *preceding page*.) Another process for the anhydrous acid, less expensive than the above, is that of Gautier, the details of which are thus given by Berzelius. The ferrocyanuret of potassium is fused without access of air, whereby it is converted into a mixture of cyanuret of potassium and carburet of iron. The mass obtained, after being pulverized and placed in a flask, is slightly moistened with water, and acted on with muriatic acid, added by small portions at a time. By a double decomposition between the cyanuret and muriatic acid, chloride of potassium and hydrocyanic acid are formed. The flask is then plunged into hot water, which causes the hydrocyanic acid to be disengaged in the form of vapour. This is passed through a tube containing chloride of calcium, and finally received in a small flask, kept cool by a freezing mixture, where it is condensed. Berzelius inclines to give the preference to this process over all others for obtaining the anhydrous acid; as the salt employed is cheap, and as the temperature of the hot water, while it is competent to volatilize the hydrocyanic acid, is not sufficient to drive over any muriatic acid.

Properties of the Medicinal Acid. Hydrocyanic acid, in the dilute state in which it is used in medicine, is a transparent, colourless, volatile liquid, possessing a taste at first cooling, afterwards somewhat irritating, and a peculiar smell. It imparts a slight and evanescent red colour to litmus. If it redden litmus strongly and permanently, the fact shows the presence of some acid impurity. It is liable to undergo decomposition if exposed to the light, but is easily kept if the bottle containing it is covered with black paint, or black paper. The French generally use bottles of blue glass. Its most usual impurities are sulphuric and muriatic acids; the former of which may be detected by evaporating a small portion of the suspected acid, when this impurity will remain; and the latter by precipitating with nitrate of silver, when so much of the precipitate as may be chloride of silver will be insoluble in boiling nitric acid, while the cyanuret of silver is readily soluble. The presence of these impurities in slight amount is injurious, only in so far as they render the strength of the acid uncertain; for they appear to confer the advantage of rendering it less liable to decomposition. Dr. Christison states that the acid prepared from the ferrocyanuret of potassium will keep for years, and its stability has been supposed to be owing to the presence of a trace of sulphuric acid. Mr. Barry, of London, adds a small portion of muriatic acid to all his medicinal hydrocyanic acid, in order to preserve it. (*Pereira*.) In opposition to the idea that the mineral acids are the preservative agents, Dr. Christison remarks that he has known medicinal hydrocyanic acid from ferrocyanuret of potassium to keep perfectly well, although nitrate of baryta, added to it, did not produce the slightest muddiness. If lead be present, it may be detected by means of hydrosulphuric acid gas, which will cause a blackish discoloration or precipitate. Hydrocyanic acid is incompatible in prescriptions with nitrate of silver, the salts of iron and copper, and most of the salts of mercury.

The medicinal acid is of different strengths, as ordered by the different pharmaceutical authorities. Formerly its strength was indicated by its specific gravity, which is lower in proportion as it is stronger; but this mode of estimate has been generally abandoned, on account of the difficulty of applying it in practice. The Pharmacopœias now, with the exception of the Dublin, rely on the saturating power as an index of strength. According to the *United States* and *London* formula, 100 grains of the acid must accurately saturate 12·7 grains of nitrate of silver, dissolved in distilled water, and produce a precipitate (cyanuret of silver) which, when washed and dried, shall weigh ten grains, and be wholly soluble in boiling nitric acid. An acid of this strength contains two per cent. of pure anhydrous acid. The test of entire solubility in boiling nitric acid, applied to the precipitate obtained by nitrate of silver, is intended to verify its nature; for if the hydrocyanic acid contain muriatic acid, part of this precipitate would be chloride of silver, not soluble in the boiling acid. The *Edinburgh* acid is directed to contain about 3·22 per cent. of anhydrous acid. The mode laid down by the College for testing its strength by nitrate of silver, admits of a variation in this particular; the stronger allowable acid being one-tenth stronger than the weaker. The *Dublin* acid, according to Dr. Barker, contains 1·6 per cent. of the anhydrous acid, as deduced from the proportion of red oxide of mercury which it is capable of dissolving. The hydrocyanic acid of the French Codex is evidently much stronger than any of these acids; but its saturating power and percentage of anhydrous acid are not given in that work.

Properties of the Anhydrous Acid. Hydrocyanic acid, perfectly free from water, is a colourless, transparent, inflammable liquid, of extreme volatility, boiling at 80°, and congealing at 5°. Its sp. gr. as a liquid is 0·6969, at the temperature of 64°; and as a vapour 0·9423. Its taste is at first cooling, afterwards burning, with an after-taste in the throat like that of bitter almonds; but from its extremely poisonous nature, it must be tasted with the utmost caution. Its odour is so strong as to produce immediate headache and giddiness; and its vapour so deleterious that it cannot be inhaled without the greatest danger. Both water and alcohol dissolve it readily. It is much more prone to undergo decomposition than the dilute acid. In the course of a few hours it sometimes begins to assume a reddish-brown colour, which becomes gradually deeper, till at length the acid is converted into a black liquid, which exhales a strong smell of ammonia. It is a very weak acid in its chemical relations, and reddens litmus but slightly. It does not form solid compounds with metallic oxides, but a cyanuret of the metal, the elements of water being exhaled. Though a product of art, it exists in some plants. It is, however, a matter of doubt, in many cases in which it is extracted from vegetables, whether it is an educt or a product. (See *Amygdala Amara*.)

Composition, &c. Hydrocyanic acid consists of one eq. of cyanogen 26·39, and one of hydrogen 1=27·39; or in volumes, of one volume of cyanogen and one volume of hydrogen without condensation. Cyanogen is a colourless gas, of a strong and penetrating smell, inflammable, and burning with a beautiful bluish-purple flame. Its sp. gr. is 1·8157. It was discovered in 1815, by Gay-Lussac, who considers it a compound radical, which, when acidified by hydrogen, becomes hydrocyanic acid. It consists of two equiv. of carbon 12·24, and one of nitrogen 14·15=26·39; or in volumes, of two volumes of carbon vapour, and one volume of nitrogen, condensed into one volume. The ultimate constituents of hydrocyanic acid are, therefore, two eq. of carbon, one of nitrogen, and one of hydrogen.

Hydrocyanic acid, in a dilute state, was discovered in 1780 by Scheele, who correctly stated its constituents to be carbon, nitrogen, and hydrogen; but the peculiar way in which they are combined was first ascertained by Gay-Lussac, by whom also the anhydrous acid was first obtained.

Medical and Toxicological Properties. Hydrocyanic acid is one of the most deadly poisons known, proving, in many cases, almost instantaneously fatal. One or two drops of the pure acid are sufficient to kill a vigorous dog in a few seconds. Notwithstanding its tremendous energy as a poison, it has been ventured upon in a dilute state as an anodyne and antispasmodic. Though occasionally resorted to as a remedy previously to 1817, it did not attract much attention until that year, when Magendie published his observations on its use in diseases of the chest, and recommended its employment to the profession. When given in medicinal doses gradually increased, it produces the following symptoms in different cases:—peculiar bitter taste; increased secretion of saliva; irritation in the throat; nausea; disordered respiration; pain in the head; giddiness; faintness; obscure vision and tendency to sleep. The pulse is sometimes quickened, at other times reduced in frequency. Occasionally salivation and ulceration of the mouth are produced. It has been most highly recommended and extensively used in complaints of the respiratory organs, and is supposed to exert a control over pulmonary inflammation, after the excitement has been diminished by blood-letting; and there is no doubt that in some instances it has been found beneficial under such circumstances. In tuberculous phthisis, though at one time boasted of as a remedy, it has no power whatever, except as a palliative for the cough. In the various affections of the chest, however, attended with dyspnœa or cough, such as asthma, hooping cough, and chronic catarrh, its use has often been decidedly beneficial, by allaying irritation or relaxing spasm. In hypertrophy of the heart, and aneurism of the aorta, it has also been used with advantage. In various affections of the stomach, characterized by pain and spasm, and sometimes attended with vomiting, but unconnected with inflammation, and supposed to depend upon a disordered condition of the nerves of the organ, hydrocyanic acid has proved beneficial in the hands of several practitioners. It has also been administered as an anodyne in several painful affections, as cancer, tic douloureux, &c., but with doubtful advantage. Sometimes it is used externally, diluted with water, as a wash in cutaneous diseases. Dr. A. T. Thomson, from his personal experience, insists particularly on its efficacy in allaying the itching and tingling in impetiginous affections.

The dose of medicinal hydrocyanic acid is from one to six or eight drops, dissolved in distilled water, or mixed with gum water or syrup. It requires to be administered with the greatest caution, on account of the minuteness of the dose, and the great variableness in strength of the acid as found in the shops. The proper plan, therefore, is to begin with a small dose, one drop for example, and gradually to increase the quantity, until some obvious impression is produced. If giddiness, weight at the top of the head, sense of tightness at the stomach, or faintness come on, its use should be discontinued. In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum, lest the new sample might prove stronger than that previously employed. When resorted to as a lotion, from thirty minims to a fluidrachm may be dissolved in a fluid-ounce of distilled water.

Hydrocyanic acid is so rapidly fatal as a poison that physicians have seldom an opportunity to treat its effects. When not immediately fatal, the symptoms produced are sudden loss of sense, trismus, difficult and rattling

respiration, coldness of the extremities, a smell of bitter almonds proceeding from the mouth, smallness of the pulse, swelling of the neck, dilatation and immobility and sometimes contraction of the pupils, convulsions, &c. The antidotes and remedies most to be relied on, are chlorine, ammonia, cold affusion, and artificial respiration. Chlorine in the form of chlorine water, or weak solutions of chlorinated lime or soda, may be exhibited internally, or applied externally. When chlorine is not at hand, water of ammonia, largely diluted, may be given, and the vapour arising from it cautiously inhaled. A case is related in the *Dublin Med. Journal*, for Nov. 1835, of poisoning by this acid, in which the diluted aromatic spirit of ammonia applied to the mouth, although not swallowed on account of the teeth being clenched, and the solid carbonate assiduously applied to the nostrils, produced speedy beneficial effects. Cold affusion was first proposed in 1828 by Herbst, who strongly recommended it from his own experiments, which were subsequently confirmed by Orfila. Its efficacy has been more recently (1839) strongly supported by the experiments of Dr. Robinson and M. Lonyet, who quickly resuscitated rabbits, apparently dead from hydrocyanic acid, by pouring on their head and spine, a stream of water artificially refrigerated.

After death from suspected poison, it is sometimes necessary, in medico-legal investigations, to ascertain whether the event was caused by this acid. If death has taken place a long time, it would be needless to search for so volatile and decomposable a poison; but it has been recognised in one instance seven days after death. The best test, in ordinary cases, is a solution of nitrate of silver, which gives a white curdy precipitate of cyanuret of silver, distinguishable from the chloride by its exhaling the peculiar odour of prussic acid on the addition of muriatic acid. In cases in which the liquid, supposed to contain the poison, is disguised by colouring and animal matter, M. Ossian Henry recommends that it should be distilled into a pure weak solution of the nitrate; when, if the suspected acid be present, cyanuret of silver will be precipitated. In order to render it certain that the precipitate is the cyanuret, in cases where its quantity is minute, M. Henry recommends that it be converted into the ferrocyanuret of sodium, which salt can be readily recognised by its forming characteristic precipitates with the sesquisalts of iron and the sulphate of copper. The conversion is effected by heating the cyanuret moderately with half its weight of common salt, which generates chloride of silver, and cyanuret of sodium. This latter is then taken up by water, and the solution filtered. To this is added a small portion of the fresh hydrated oxide of iron, obtained by precipitating a solution of sulphate of iron by potassa. The solution is again filtered, and moderately heated. Ferrocyanuret of sodium is thus formed, the least trace of which strikes a blue colour with the sulphate of sesquioxide of iron, and a brown one with the sulphate of copper. (*Amer. Journ. of Pharm.* ix. 236, from the *Journ. de Pharm.*)

ACIDUM MURIATICUM DILUTUM. U. S., *Ed. Dub.* ACIDUM HYDROCHLORICUM DILUTUM. Lond. *Diluted Muriatic Acid.*

“Take of Muriatic Acid *four fluidounces*; Distilled Water *twelve fluidounces*. Mix them in a glass vessel. The specific gravity of this acid is 1.046.” U. S.

The *London* and *Edinburgh* directions are the same as those of the U. S. Pharmacopœia. The U. S. and London diluted acids are identical; but the

Edinburgh muriatic acid having a density of 1·17, instead of 1·16 (*U. S., Lond.*), the diluted acid of that College is somewhat stronger, and is stated to be 1·050. The *Dublin College* mixes *ten measures* of Muriatic Acid with *eleven* of Distilled Water, and states the density of the acid to be 1·080.

It is convenient to have an officinal diluted muriatic acid, and, at present, all the Pharmacopœias give a formula for it. The acids of the *U. S., London*, and *Edinburgh Pharmacopœias* virtually agree in strength; that of the *Dublin College* is nearly twice as strong. For an account of the medicinal properties of muriatic acid, see *Acidum Muriaticum*. The dose of the diluted acid is from twenty to sixty drops, of the *Dublin* acid, about half this quantity, mixed with water or other convenient vehicle. The *Dublin College* employs this acid, as a chemical agent, in the preparation of *Calcis Phosphas Præcipitatum*.
B.

ACIDUM NITRICUM DILUTUM. *U. S., Lond., Ed., Dub.*
Diluted Nitric Acid.

“Take of Nitric Acid *a fluidounce*; Distilled Water *nine fluidounces*. Mix them in a glass vessel. The specific gravity of this acid is 1·08.” *U. S.*

The *London* formula is the same as that of the *U. S. Pharmacopœia*.

“Mix together *one fluidounce* of Pure Nitric Acid (*D. 1·500*), and *nine fluidounces* of Distilled Water. If the Commercial Nitric Acid of *D. 1·390* be used, *one fluidounce and five fluidrachms and a half* are required. The density of this diluted acid is 1·077.” *Ed.*

“Take of Nitric Acid *by measure, three parts*; Distilled Water, *by measure, four parts*. Mix, avoiding the noxious vapours. The specific gravity of this acid is 1·280.” *Dub.*

At present all the Pharmacopœias embrace Diluted Nitric Acid, for convenience in prescribing. The acids of the *U. S., London*, and *Edinburgh Pharmacopœias* are of the same strength, being for equal volumes with the strong acid, a little more than one-tenth its strength. The acid of the *Dublin College* is somewhat less than half as strong as the concentrated acid, and is, therefore, nearly five times as strong as the other officinal acids.

The medicinal properties of the diluted acid are the same as those of the strong acid. (See *Acidum Nitricum*.) The dose of the weaker acid is from twenty to forty drops three times a day, sufficiently reduced with water at the time of taking it; of the stronger (*Dublin* acid), from five to ten drops.

Diluted nitric acid is used by the *Dublin College*, as a chemical agent merely, in preparing *Calomelas Præcipitatum*, *Hydrargyri Acetas*, and *Hydrargyri Oxydum Nitricum*. A diluted nitric acid is used by the *Edinburgh College* for preparing the red oxide of mercury; but it is directed to have the density of 1·280, and is, therefore, not the officinal diluted acid of the *College*.

ACIDUM NITROMURIATICUM. *U. S., Dub.* *Nitromuriatic Acid.*

“Take of Nitric Acid *four fluidounces*; Muriatic Acid *eight fluidounces*. Mix them in a glass vessel, and, when effervescence has ceased, keep the product in a well-stopped glass bottle, in a cool and dark place.” *U. S.*

The *Dublin* formula need not be given; as it is the original of that now for the first time introduced into the *U. S. Pharmacopœia*.

Nitromuriatic acid is the *aqua regia* of the earlier chemists, so called from its property of dissolving gold. Nitric and muriatic acids, when mixed

together, mutually decompose each other. The quantities necessary to render the decomposition complete, are one equivalent of each. One eq. of hydrogen of the muriatic acid forms water with one eq. of oxygen of the nitric acid, which consequently becomes nitrous acid, and chlorine is set free. The preparation, therefore, after the reaction is over, is a solution of nitrous acid and chlorine in water.

As the acids, considered dry, must be used in the proportion of their equivalents, it is easy to calculate in what proportion the officinal acids of the U. S. Pharmacopœia must be mixed, so as to contain equivalent quantities of the dry acids. Thus 67·7 parts of the U. S. nitric acid, and 114·4 parts of the U. S. muriatic acid, contain respectively one eq. of dry acid. It hence follows that the U. S. officinal acids, for complete decomposition, must be mixed in this proportion, or in the ratio of 10 to 17 nearly; and the mixture will contain, by calculation, somewhat less than 20 per cent. of free chlorine, assuming that none is lost by effervescence. This ratio by weight, turned into volumes, would be 1 measure of nitric acid to 2·19 measures of muriatic acid. But the formula calls for 1 measure of nitric acid to 2 measures of muriatic acid, and hence it is evident that the nitric acid is used in an amount, somewhat more than sufficient to decompose the whole of the muriatic acid. These calculations, of course, apply also to the Dublin nitromuriatic acid, the slight difference between the officinal density of the Dublin and U. S. nitric acid (1·49 to 1·5) not affecting sensibly the result.

The affinity of chlorine and nitrous acid for water being much less than that of muriatic and nitric acids for the same liquid, the mixture of the *strong acids* is always attended with the production of effervescence. To prevent the loss of chlorine, Dr. Duncan recommends the immediate dilution of the mixture with an equal quantity of water. On account of these objections to the use of the strong acids, it is best to employ good *ordinary acids* of commerce. The strength of these may be stated as averaging 1·15 for muriatic, and 1·34 for nitric acid; and the proportions in which they should be mixed is about 26 parts by weight of the former to 25 of the latter. The mixture contains about 15 per cent. of chlorine. The decomposition, in this case, takes place slowly, and the resulting solution of chlorine may be kept without inconvenience.

Properties. Nitromuriatic acid has a golden-yellow colour, and emits the smell of chlorine. It possesses the power of dissolving gold and platinum, owing, solely, it is generally supposed, to the presence of chlorine; but, according to Millon, the action does not take place without the presence of nitrous acid. It requires to be kept in a cool, dark place, on account of its liability to lose its chlorine by heat, or to have it converted, by the action of light, into muriatic acid, in consequence of the decomposition of water. On account of its liability to decomposition, it should not be made by the apothecary until it is wanted for use, and then only in the quantity ordered; the formula being introduced, merely as a guide for the proportions. The nitric and muriatic acids, as sold in the shops, are sometimes so weak that when mixed they will not readily act on gold-leaf. When this is the case, their solvent power may be rendered effective by the addition of a little sulphuric acid, which, by its superior attraction for water, concentrates the other acids, and produces an immediate action, accompanied by the evolution of chlorine.*

* For further information in relation to nitromuriatic acid, the reader is referred to a paper in the third volume of the Journal of the Philadelphia College of Pharmacy, by Daniel B. Smith, President of the College.

Medical Properties and Uses. Nitromuriatic acid was brought into notice as a remedy, in consequence of the favourable report of its efficacy as an external remedy in hepatitis, made by Dr. Scott, formerly of Bombay. When thus employed, it produces a tingling sensation in the skin, thirst, a peculiar taste in the mouth, and occasionally soreness of the gums and plentiful ptyalism; and at the same time stimulates the liver, as is evinced by an increased flow of bile. It is used either by sponging, or in the form of bath. When applied in the former way, the acid is first diluted so as to have the acidity of strong vinegar. When used as a bath, three gallons of water contained in a deep, narrow, wooden tub, may be acidulated with six fluidounces of the acid. In this the feet and legs are to be immersed for twenty minutes, or half an hour. The bath may be employed at first daily, and afterwards twice or thrice a week; and the sponging may be used at the same time. The bath is said to be effective in promoting the passage of biliary calculi. The acid may be used also internally, principally in hepatic and syphilitic diseases. The dose in this case is three or four drops, sufficiently diluted with water. B.

ACIDUM PHOSPHORICUM DILUTUM. *Lond. Diluted Phosphoric Acid.*

“Take of Phosphorus *an ounce*; Nitric Acid *four fluidounces*; Distilled Water *ten fluidounces*. Add the Phosphorus to the Nitric Acid mixed with the Water in a glass retort placed in a sand-bath; then apply heat until eight fluidounces are distilled. Put these again into the retort, that eight fluidounces may distil, which are to be rejected. Evaporate the remaining liquor in a platinum capsule until only two ounces and six drachms remain. Lastly, add to the acid, when it is cold, as much distilled water as may be sufficient to make it accurately measure twenty-eight fluidounces.” *Lond.* The specific gravity of this acid is 1.064. One hundred grains of it saturate forty-two grains of carbonate of soda. Imperial measure is to be understood in this formula.

The process for this new officinal of the London College may be thus explained. Phosphorus, when added to strong nitric acid, decomposes it with explosion and rapid combustion; but when distilled with the diluted acid the action takes place slowly, the phosphorus gradually melts and becomes oxidized, and nitric oxide is evolved. Before, however, the whole of the phosphorus is acidified, the nitric acid will have distilled over; and hence the necessity of returning it into the retort, as directed by the College, in order to complete the acidification of the phosphorus. When this has been completed, all remains of nitric acid are driven off by the evaporation in the platinum capsule; and the residue, which contains all the phosphoric acid that can be generated from an ounce of phosphorus, is brought to a standard degree of dilution, by the addition of sufficient distilled water to make it measure twenty-eight fluidounces. (See *Acidum Nitricum* and *Phosphorus*.)

Phosphoric acid may be obtained more economically than by the above process, by decomposing phosphate of lime (earth of bones) by sulphuric acid, saturating the superphosphate formed with carbonate of ammonia, which generates phosphate of ammonia in solution with precipitation of phosphate of lime, and finally decomposing the phosphate of ammonia by a red heat in a platinum crucible. The ammonia is thus expelled, and the solid residuum will be the phosphoric acid. Wackenroder has given another process for medicinal phosphoric acid, which requires the use of alcohol,

and is, therefore, ineligible. (See *Amer. Journ. of Pharm. for July, 1842.*) Platinum vessels are necessary in the different processes for preparing phosphoric acid, because this acid, when concentrated, acts on glass.

Properties. Diluted phosphoric acid is a colourless, inodorous, sour liquid, acting strongly on litmus, and possessing powerful acid properties. Although evaporated so as to become dense, it is not powerfully corrosive like the other mineral acids. From its saturating power it is shown to contain 10·5 per cent. of real phosphoric acid. With chloride of barium and nitrate of silver it forms precipitates, (the phosphates of baryta and silver,) which are readily soluble in nitric acid. If the tests mentioned give a precipitate not soluble in this acid, they prove the presence—the chloride of barium, of sulphuric acid or a sulphate; the nitrate of silver, of muriatic acid or a chloride. If carbonate of soda causes a precipitate, phosphate of lime, or some other phosphate insoluble in water, is probably held in solution. When the diluted acid is evaporated to dryness and heated to redness, it becomes a transparent, white, brittle, fusible solid, formerly called *glacial phosphoric acid*, now denominated *metaphosphoric acid*, and consisting of one eq. of phosphoric acid and one of water. Phosphoric acid, considered dry, consists of one eq. of phosphorus 31·4, and five of oxygen 40=71·4.

Medical Properties and Uses. Diluted phosphoric acid, like the other mineral acids, is deemed tonic and refrigerant. It is preferable in point of flavour to the diluted sulphuric acid, and is less apt to disturb the digestive functions. Various powers have been ascribed to it, such as allaying pain and spasm, strengthening the sexual organs, preventing the morbid secretion of bony matter, as in exostosis and ossification, and correcting phosphatic deposits in the urine, on the ground of its power of dissolving phosphate of lime. It has been recommended in leucorrhœa, when the secreted fluid is thin and acrid, in hysteria, and diabetes. In the latter disease Dr. Paris found it to allay the thirst more effectually than any other acid drink. The dose is from twenty drops to a teaspoonful, diluted with water. B.

ACIDUM SUCCINICUM. *Dub. Succinic Acid.*

“Take of Amber reduced to coarse powder, and of pure sand, each, *one part*. On the application of heat gradually increased, an acid liquor, an oil, and the acid in the crystallized form will distil over. The latter should be received on bibulous paper, and exposed to a strong pressure to expel the oil, and again sublimed. By filtration through bibulous paper, the oil may be obtained separate from the acid liquor.” *Dub.*

The above formula has for its object to obtain the oil of amber, as well as succinic acid; but our remarks will be confined, in this place, to the acid, the oil being described under another head. (See *Oleum Succini*.) Amber contains succinic acid ready formed, associated with volatile oil, certain resins, and other substances. (See *Succinum*.) When distilled, it swells considerably, and a yellow liquid first comes over; after which the succinic acid sublimes, and condenses in needles in the neck of the retort and on the sides of the receiver. At last the matter suddenly ceases to swell, and the process is finished; for after this time, very little succinic acid is disengaged, but a thick and dark coloured oil rises, which renders the acid impure. The College directs the admixture of sand, to prevent the inconvenience of the amber swelling too much by the heat.

Several processes have been proposed to purify succinic acid. The best is that of Morveau, which consists in dissolving the acid in twice its weight

of nitric acid, and evaporating the solution to dryness. In this way the oil is decomposed, while the succinic acid remains unaltered. This is then washed in a little ice-cold water, next dissolved in boiling water, and crystallized.

Properties. Succinic acid, when pure, is a white, transparent solid, crystallizing in prisms, and having a somewhat acid taste. It reddens litmus strongly. It exists in the resins of certain coniferæ, and is a product of the oxidation of stearic and margaric acid. In the form of *succinate of ammonia*, it is used, in analysis, to precipitate sesquioxide of iron. Exposed to heat it melts, and above the boiling point of water is partly sublimed and partly decomposed. It dissolves in five times its weight of cold, and twice its weight of boiling water. It is soluble also in cold alcohol, and much more so in boiling alcohol. When anhydrous it consists of four eqs. of carbon 24.48, two of hydrogen 2, and three of oxygen 24 = 50.48 ($C_4H_2O_3$). It differs, therefore, from acetic acid, only in containing one eq. less of hydrogen. The sublimed acid consists of two eqs. of dry acid and one of water $2(C_4H_2O_3) + HO$.

Succinic acid is at present never used in medicine, and ought to be expunged from the officinal catalogue. Since our last edition, it has been abandoned by the Edinburgh College.

B.

ACIDUM SULPHURICUM AROMATICUM. U.S., Ed., Dub. *Aromatic Sulphuric Acid. Elixir of Vitriol.*

"Take of Sulphuric Acid *three fluidounces and a half*; Ginger, bruised, *an ounce*; Cinnamon, bruised, *an ounce and a half*; Alcohol *two pints*. Add the Acid gradually to the Alcohol, and digest, in a close vessel, for three days; then add the Ginger and Cinnamon, and macerate for a week; lastly, filter through paper." U.S.

"Take of Sulphuric Acid (commercial) *three fluidounces and a half*; Rectified Spirit *a pint and a half* [Imp. meas.]; Cinnamon, in moderately fine powder, *an ounce and a half*; Ginger, in moderately fine powder, *an ounce*. Add the acid gradually to the spirit, let the mixture digest at a very gentle heat for three days in a closed vessel; mix the powders, moisten them with a little of the acid spirit, let the mass rest for twelve hours, and then put it into a percolator and transmit the rest of the acid spirit. This preparation may also be made by digesting the powders for six days in the acid spirit, and then straining the liquor." Ed.

The *Dublin* process is substantially the same as those of the U. S. and Edinburgh Pharmacopœias, and therefore need not be copied.

The original of the formulas here given for elixir of vitriol was the process contained in the former Edinburgh Pharmacopœia, which was adopted, with slight alteration, in the U. S. and Dublin standards. The present formula of the Edinburgh College differs from their original one, in substituting for the weights of the acid and spirit, the nearest equivalent measures, and in giving the alternative of preparing by displacement. The same substitution was made in the formula when it was first adopted in the U. S. Pharmacopœia, and hence the two formulas are virtually the same. The only difference is in the proportion of the spirit, which is 32 wine fluidounces in the U. S. formula, and 30 Imperial fluidounces in the Edinburgh. This circumstance makes the U. S. preparation somewhat weaker in acids than the Edinburgh, because more diluted with spirit.

Properties. Aromatic sulphuric acid is a reddish-brown liquid, of a peculiar aromatic odour, and, when sufficiently diluted, of a grateful acid taste. It has been supposed by some to be a kind of ether, its main ingredients

justifying such a suspicion; but the late Dr. Duncan, who originally held this opinion, satisfied himself that the alcohol and sulphuric acid, in the proportions here employed, do not produce a single particle of ether. It must, therefore, be viewed merely as sulphuric acid diluted with alcohol, and containing the essential oils of ginger and cinnamon.

Medical Properties and Uses. This valuable preparation, commonly called *elixir of vitriol*, is a simplification of the acid elixir of Mynsicht. It is tonic and astringent, and affords the most agreeable mode of administering sulphuric acid. It is very much employed in debility with night sweats, in loss of appetite, and in the convalescence from fevers, especially those of the intermittent type. It is often given in conjunction with cinchona, the taste of which it serves to cover, and, by increasing the solubility of the febrifuge principles of the bark, appears to increase its efficacy. (See *Infusum Cinchonæ Compositum*.) In hæmoptysis and other hæmorrhages, when not attended with obvious inflammation, it frequently proves useful in stopping the flow of blood. The dose is from ten to thirty drops in a wineglassful of water, repeated two or three times a day. Care must be taken that the teeth are not injured by the acid.

Off. Prep. Infusum Cinchonæ Compositum, U. S.

B.

ACIDUM SULPHURICUM DILUTUM. U. S., Lond., Ed., Dub. *Diluted Sulphuric Acid.*

“Take of Sulphuric Acid *a fluidounce*; Distilled Water *thirteen fluidounces*. Add the Acid gradually to the Water, in a glass vessel, and mix them. The specific gravity of this acid is 1.09.” U. S.

“Take of Sulphuric Acid *a fluidounce and a half*; Distilled Water *fourteen fluidounces and a half*. Add the Acid gradually to the Water, and mix them.” Lond.

“Mix together *one fluidounce* of Sulphuric Acid and *thirteen fluidounces* of Water. The density of this preparation is about 1.090.” Ed.

“Take of Pure Sulphuric Acid *one part*; Distilled Water *seven parts*. Gradually add the Acid to the Water. The specific gravity of this acid is 1.084.” Dub.

This preparation is sulphuric acid, diluted to such an extent as to make it convenient for prescription. The U. S. and *Edinburgh Pharmacopœias* agree in making the strong acid to the water as *one to thirteen* in volume, equivalent nearly to *one to seven* in weight, the ratio adopted by the *Dublin College*. There is, accordingly, a virtual agreement in the strength and density of the acid by these three processes; but unfortunately the formula of the London College gives an acid considerably stronger. The coincident processes afford an acid containing about 13 per cent. of the strong liquid acid; while the London acid contains 16 per cent., and has a specific gravity as high as 1.11. According to Mr. Phillips, a fluidrachm (Imp. meas.) of the London acid contains about ten grains of the strong acid, and will saturate twenty-eight grains of crystallized carbonate of soda. The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposits a grayish-white powder, which is sulphate of lead, and from which the diluted acid should be poured off for use. This noxious salt is thus got rid of, but sulphate of potassa, another impurity in the strong acid, still remains in solution. To avoid these impurities, the Dublin College directs the dilution of *pure* sulphuric acid. The presence of a small portion of sulphate of potassa will do no

harm; but if it should be fraudulently introduced into the strong acid to increase its specific gravity, its amount may be ascertained by saturating the acid, after dilution, with ammonia, and expelling, by a red heat, the sulphate of ammonia formed. Whatever sulphate of potassa is present will remain behind.

Medical Properties and Uses. Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in low typhoid fevers, and often with advantage. In the convalescence from protracted fevers, it often acts beneficially as a tonic, exciting the appetite and promoting digestion. As an astringent, it is employed in colliquative sweats, passive hemorrhages, and diarrhœas dependent on a relaxed state of the mucous membrane of the intestines. In calculous affections attended with phosphatic sediments, it is the proper remedy, being preferable to muriatic acid, as less apt, by continued use, to disorder the stomach. Externally it is used as an ingredient in gargles for ulcerated sorethroat and for checking excessive pytalism, and as a wash for cutaneous eruptions and ill-conditioned ulcers. The dose is from ten to thirty drops three times a day, in a wineglass or two of plain or sweetened water. It is added with advantage to infusions of cinchona, the organic alkalies of which it tends to hold in solution. As it is apt to injure the teeth, it is best taken by sucking it through a quill. It is much less used in the United States than the elixir of vitriol, which possesses nearly the same medical properties. An elegant form for giving it is the compound infusion of roses. (See *Acidum Sulphuricum Aromaticum*, and *Infusum Rosæ Compositum*.)

Diluted sulphuric acid is used as a chemical agent to prepare *Acidum Citricum*, *Lond., Ed., Dub.*; *Acid. Tartaricum*, *Lond., Ed.*; *Aconitina*, *Lond.*; *Antimonii Sulphuretum Præcipitatum*, *U. S., Lond., Ed., Dub.*; *Strychnia*, *U. S., Lond.*; *Veratria*, *U. S., Lond.*

Off. Prep. *Infusum Rosæ Compositum*, *U. S., Lond., Ed., Dub.*; *Morphiæ Sulphas*, *U. S.*; *Quininæ Sulphas*, *Dub.*; *Zinci Sulphas*, *Lond.* B.

ACIDUM SULPHURICUM PURUM. *Ed., Dub.* *Pure Sulphuric Acid.*

"If Commercial Sulphuric Acid contain nitrous acid, heat *eight fluid-ounces* of it with *ten and fifteen grains* of sugar, at a temperature not quite sufficient to boil the acid, till the dark colour at first produced shall have nearly or altogether disappeared. This process removes nitrous acid. Other impurities may be removed by distillation, which on the small scale is easily managed by boiling the acid with a few platinum chips in a glass retort by means of a sand-bath or gas flame, rejecting the first half ounce." *Ed.*

"Take of Commercial Sulphuric Acid *a pound*. Put the acid into a retort of flint glass, attach a receiver of the same kind, and with the junctures of the vessels left open, let heat be applied to the retort until one-twelfth part of the liquor shall have distilled over: this, as it contains water, should be rejected. The receiver being again applied, the residuum is to be distilled to dryness. A few slips of platinum put into the acid in the retort, will restrain the ebullition, which otherwise would be too violent. The specific gravity of this acid is 1.845. Let the acid be kept in well closed vessels." *Dub.*

The object of these processes is the purification of commercial sulphuric acid. This acid contains the sulphates of lead and potassa, amounting not unfrequently to three or four per cent.; and nitrous acid is almost always present. The salts mentioned, not being volatile, are effectually got rid of

by distillation, as directed in the formulæ. The manner of conducting the distillation is explained at page 48, under the head of *Acidum Sulphuricum*. The mode of detecting nitrous acid is pointed out at page 46. If present in the commercial acid, the Edinburgh College directs, before distilling it, that it should be heated with a small proportion of sugar, according to the plan of Wackenroder. The acid impurity and sugar mutually decompose each other, and the products are dissipated by the heat. The acid is at first rendered dark and opaque, but gradually becomes pale yellow, if kept for two hours near the boiling point. Nitrous acid is hurtful to the sulphuric, when the latter is used to obtain muriatic acid, which consequently becomes contaminated with chlorine. Hence the Edinburgh College uses *pure* sulphuric acid in the formula for preparing muriatic acid. If the commercial sulphuric acid contain arsenic, it should not be distilled, but rejected. The tests for this impurity are given at page 47.

It is, perhaps, an advantage to have an officinal *pure* sulphuric acid. The least danger of introducing lead into the system, when exhibiting the preparations containing sulphuric acid, should be carefully avoided. It is true that the commercial acid, upon dilution, lets fall the sulphate of lead; but can we be certain that the precipitate is always removed from the preparation into which the acid enters? When the acid is required as a mere chemical agent, or for forming sulphates, the commercial acid is sufficiently pure.

There is a want of precision in the nomenclature of the officinal sulphuric acids in the Edinburgh and Dublin Pharmacopœias. The Edinburgh College adopts the names "*Acidum Sulphuricum*" and "*Acidum Sulphuricum Purum*," and translates them in three ways in the formulas,—"*commercial sulphuric acid*," "*pure sulphuric acid*," and "*sulphuric acid*." The last name is ambiguous, and may mean either the commercial or pure acid. The Dublin College adopts the names "*Acidum Sulphuricum Venale*" and "*Acidum Sulphuricum Purum*," but, in the formulas, frequently uses the indefinite term "*Acidum Sulphuricum*." We shall assume that the indefinite expressions of both Pharmacopœias mean the commercial acid.

According to the views here taken, pure sulphuric acid should be used, especially in forming "*diluted sulphuric acid*" and "*aromatic sulphuric acid*." In neither of these preparations is it employed by the Edinburgh College, and only to form the diluted acid by the Dublin. Where a dilute acid is required as a chemical agent, and not as a medicine, it might be directed, in the formula, to be formed by the addition of a determinate quantity of water to the commercial acid. The Edinburgh College considers it necessary to use the "*pure sulphuric acid*," though acting merely as a chemical agent, in preparing *Acidum Aceticum* and *Acidum Muriaticum Purum*.

B.

ACIDUM TANNICUM. U. S. Tannic Acid. Tannin.

"Take of Galls, in powder, Sulphuric Ether, each, *a sufficient quantity*. Put into a glass adapter, loosely closed at its lower end with carded cotton, sufficient powdered Galls to fill about one half of it, and press the powder slightly. Then fit the adapter accurately to the mouth of a receiving vessel, fill it with the Sulphuric Ether, and close the upper orifice so as to prevent the escape of the ether by evaporation. The liquid which passes separates into two unequal portions, of which the lower is much smaller in quantity and much denser than the upper. When the ether ceases to pass, pour fresh portions upon the Galls, until the lower stratum of liquid

in the receiver no longer increases. Then separate this from the upper, put it into a capsule, and evaporate with a moderate heat to dryness. Lastly, rub what remains into powder.

“The upper portion of liquid will yield by distillation a quantity of ether, which, when washed with water, may be employed in a subsequent operation.” *U. S.*

This is the process of M. Pelouze. It may be conducted in an ordinary displacement apparatus. The sulphuric ether employed should be that of the shops, containing a small proportion of water, which is necessary to the success of the operation. Should the ether contain no water, it should be washed with this fluid, which answers the double purpose of depriving it of alcohol, and rendering it sufficiently hydrous. To obtain the tannic acid quite pure, the lower stratum may be washed with ether after the separation of the upper, and evaporated in a vacuum with sulphuric acid. The explanation of the process first given was that the water in the ether dissolves the tannic acid to the exclusion of all the other principles of the galls, and forms a saturated solution, which separates from the ether, and constitutes the lower stratum in the receiver. From the experiments of M. Beral, there is reason to believe that the tannic acid is not merely dissolved by the water, but forms with it and a portion of the ether, a definite compound, which is essentially liquid, and is decomposed during the evaporation; the ether and water escaping, and the solid tannic acid being left behind. The upper and larger stratum in the receiver consists of ether, holding colouring matter with a small proportion of gallic and tannic acids in solution. From 30 to 35 per cent. of tannic acid may be obtained from galls by this process, if properly conducted.*

For practical purposes it is unnecessary to obtain the tannic acid quite pure. It is probably sufficiently so when extracted by the following simple process of Leconnet, given in Christison's Dispensatory. The powder of galls is macerated in a bottle, with just enough ether to moisten it, for twenty-four hours, and then expressed in a powerful press; and the process of maceration and expression is repeated, in the same way, until the powder is exhausted. The liquors are mixed, the ether distilled off, and the residue dried by means of a vapour-bath. It is stated that 60 per cent. of tannic acid, but very slightly coloured, may be got in this way. As gallic acid exists but in very small proportion in galls, being chiefly produced by the reaction of atmospheric air upon tannic acid in the process for extracting it, very little of that principle is found in the ethereal extract, and the amount of colouring matter taken up by the ether, will scarcely interfere with the medicinal efficacy of the preparation.

The term *tannin* was originally applied to a principle or principles existing in many vegetables, having a very astringent taste, and the property of producing a white flocculent precipitate with the solution of gelatin, and a black precipitate with the salts of the sesquioxide of iron. As obtained, however, from different plants, tannin was found to exhibit some difference of properties, and chemists have recognised two kinds, one existing in oak bark, galls, &c., distinguished by producing a bluish-black precipitate with the salts of the sesquioxide of iron, and the other existing in Peruvian bark, catechu, &c., and characterized by producing a greenish-black or dark olive precipitate with the same salts. The former is the one which

* The various circumstances in which the process is liable to vary in consequence of difference in the character of the menstruum, have been detailed and explained in a paper by Dr. Robert Bridges, contained in the *Am. Journ. of Pharmacy*, vol. 14, page 40, to which the reader is referred.

has received most attention, and from an examination of which the characters of tannin have generally been given. It is the substance described in this article. It will probably be found that the latter is essentially distinct from the tannin of galls, and probably different in different vegetables. One striking peculiarity of the tannin of galls is its facility of conversion into gallic acid, which is wanting in some at least of the other varieties. Since the publication of the experiments of M. Pelouze in relation to tannin, this substance has been universally admitted to rank with the acids, and is, therefore, now generally denominated tannic acid. Dr. Kane calls the ordinary variety procured from galls, for the sake of distinction, *gallo-tannic acid*.

Properties. Pure tannic acid is solid, uncrystallizable, white or slightly yellowish, inodorous, strongly astringent to the taste without bitterness, very soluble in water, much less soluble in alcohol and ether, especially when anhydrous, and insoluble in the fixed and volatile oils. It may be kept unchanged in the solid state; but its aqueous solution, when exposed to the air, gradually becomes turbid, and deposits a crystalline matter, consisting chiefly of gallic acid. During the change, oxygen is absorbed, and an equal volume of carbonic acid disengaged. Exposed to heat, it partly melts, swells up, blackens, takes fire, and burns with a brilliant flame. Its solution reddens litmus, and it combines with most of the salifiable bases. With potassa it forms a compound but slightly soluble, and is therefore precipitated by this alkali or its carbonates from a solution which is not too dilute, though a certain excess of alkali will cause the precipitate to be redissolved. Its combination with soda is much more soluble; and this alkali affords no precipitate unless with a very concentrated solution of tannic acid. With ammonia its relations are similar to those with potassa. Baryta, strontia, lime, and magnesia, added in the state of hydrates, form with it compounds of little solubility. The same is the case with most of the metallic oxides, when presented, in the state of salts, to a solution of the tannate of potassa. Many of the metallic salts are precipitated by tannic acid even in the uncombined state, especially those of lead, copper, silver, uranium, chromium, mercury, and the protosalts of tin. With the sesquisalts of iron it forms a black precipitate, which is a compound of tannic acid and the sesquioxide of iron, and is the basis of ink. It does not disturb the solutions of the pure protosalts of iron. Several of the alkaline salts precipitate it from its aqueous solution, either by the formation of insoluble compounds, or by simply abstracting the solvent. Tannic acid unites with all the vegetable alkalies, forming compounds which are for the most part of a whitish colour and but very slightly soluble in water; though they are soluble in the vegetable acids, especially the acetic, and in alcohol, and in this latter respect differ from most of the compounds which tannic acid forms with other vegetable principles. On account of this property of tannic acid, it has been employed as a test of the vegetable alkalies; and it is so delicate, that it will throw down a precipitate from their solution even when too feeble to be disturbed by ammonia. It has an affinity for several acids, and when in solution affords precipitates with the sulphuric, nitric, muriatic, phosphoric, and arsenic acids, but not with the oxalic, tartaric, lactic, acetic, or citric. The precipitates are compounds of tannic acid with the respective acids mentioned, and are soluble in pure water, but insoluble in water with an excess of acid. Hence, in order to ensure precipitation, it is necessary to add the acid in excess to the solution of tannic acid. It precipitates also solutions of starch, albumen, and gluten, and forms with gelatin an insoluble compound, which is

the basis of leather. Its ultimate constituents are carbon, hydrogen, and oxygen; and its formula, according to Liebig, is $C_{18}H_8O_{12}$, or $C_{18}H_5O_9 + 3HO$.

Medical Properties and Uses. Tannic acid, being the chief principle of vegetable astringents, is capable of exerting on the system the same effects with this class of medicines, and may be given in the same complaints. It has an advantage over the astringent extracts in the comparative smallness of its dose, which renders it less apt to offend an irritable stomach. In most of the vegetable astringents, it is associated with more or less bitter extractive, or other principle which modifies its operation, and renders the medicine less applicable than it otherwise would be, to certain cases in which there is an indication for pure astringency without any tonic power. Such is particularly the case with the active hemorrhages; and tannic acid, in its separate state, is in these cases preferable to the native combinations in which it ordinarily exists. Dr. Porta, an Italian physician, employed it with great success in the treatment of uterine hemorrhage, and published the results of his experience in 1827. M. Cavalier afterwards used it successfully in the same complaint, and found it effectual also in a case of bleeding from the rectum. It has been highly recommended by Dr. Charvet for checking excessive sweats. There is no doubt that it would be found a useful remedy in most forms of hemorrhage, after a sufficient reduction of arterial action by depletory measures. In diarrhœa also it would probably be more beneficial than ordinary astringents, as less liable to irritate the stomach and bowels. It may be given in the dose of from two to five grains. The only disadvantage which has been experienced from it, when taken in excess, is obstinate constipation. W.

ACONITINA. *Lond.*

Aconitina.

“Take of Aconite Root, dried and bruised, *two pounds*; Rectified Spirit *three gallons* [Imperial measure]; Diluted Sulphuric Acid, Solution of Ammonia, Purified Animal Charcoal, each, *a sufficient quantity*. Boil the Aconite with a gallon of the Spirit, for an hour, in a retort with a receiver fitted to it. Pour off the liquor, and again boil the residue with another gallon of the Spirit and with the spirit recently distilled, and pour off the liquor also. Let the same be done a third time. Then press the Aconite, and having mixed all the liquors and filtered them, distil the spirit. Evaporate the remainder to the proper consistence of an extract. Dissolve this in water and filter. Evaporate the solution with a gentle heat, to the consistence of syrup. To this add of Diluted Sulphuric Acid, mixed with distilled water, sufficient to dissolve the aconitina. Next drop in Solution of Ammonia, and dissolve the precipitated aconitina in Diluted Sulphuric Acid, mixed as before with water. Then mix in the Animal Charcoal, occasionally shaking for a quarter of an hour. Lastly filter, and having again dropped in Solution of Ammonia so as to precipitate the Aconitina, wash and dry it.” *Lond.*

The name adopted by the London College for the alkaline principle extracted from aconite is objectionable, as of unnecessary length, and not in accordance with the general nomenclature of the vegetable alkalies. Aconitia is a preferable name. The principle probably exists in the plant combined with a vegetable acid, forming a soluble salt. In the above process, this is first extracted by alcohol, then taken up from the alcoholic extract by water, and afterwards converted into a sulphate by the addition of dilute sulphuric

acid. The sulphate is decomposed by ammonia which precipitates the aconitia, and this is purified by being once more combined with sulphuric acid, then decolorized by animal charcoal, and again precipitated by ammonia. Care is requisite, in conducting the process, not to add too great an excess of the water of ammonia, which diminishes the product, probably by dissolving the aconitia.

Properties. Aconitia, when freshly precipitated, is said to be white and in the form of a hydrate; but it speedily parts with its water, and forms a brownish, brittle mass. (Soubeiran, *Trait. de Pharm.* ii. 716.) It is thought not to be crystallizable. Obtained by evaporating its alcoholic solution, it is described as being in the form of a transparent, colourless mass, having a glassy lustre. In powder, it is white with a yellowish tinge. It is inodorous, and of a bitter and acrid taste, producing a benumbing impression on the tongue. The acrimony, however, is ascribed by some to a distinct principle associated with it, from which it may be freed by repeated solution in dilute acids and subsequent precipitation. It is unalterable in the air, and fusible by a gentle heat. At a high temperature it is decomposed and entirely dissipated. It is sparingly soluble in water, requiring for solution 150 parts of cold and 50 of boiling water. (Phillips.) Alcohol and ether dissolve it readily. It neutralizes the acids; but its salts are not crystallizable. That it contains nitrogen is proved by the evolution of ammonia, when it is decomposed by heat. A spurious substance has sometimes been sold under the same name, which was nearly or quite inert. It wanted some of the properties above mentioned as characteristic of aconitia.

Medical Properties and Uses. This vegetable principle exercises a powerful influence over the animal economy. One fiftieth of a grain dissolved in alcohol destroyed a sparrow in a few minutes, and the same quantity administered to an elderly female is said to have nearly proved fatal. It is not used internally as a remedy; but Dr. Turnbull has advantageously resorted to its external application. According to this writer, it produces in the skin a sensation of heat and prickling, followed by numbness and a feeling of constriction; and the effect continues, according to the quantity applied, from two to twelve hours or more. He found it not to act as a rubefacient, or at least but slightly so. Applied very much diluted and in minute quantity to the eye, it causes contraction of the pupil, with an almost intolerable sense of heat and tingling. The affections in which Dr. Turnbull employed it with benefit, were neuralgia, gout, and rheumatism. He recommends it either in alcoholic solution, in the proportion of a grain to a fluidrachm, or in the form of an ointment, made by rubbing up two grains of the alkali first with six drops of alcohol and then with a drachm of lard. These proportions are sufficiently large to begin with, but may be gradually increased to four or five, or even eight grains to the drachm. The preparation should be applied by friction over the part affected, which should be continued till the peculiar sensation above described is produced, and may be repeated three or four times, or more frequently, during the day. No good can be expected unless the sensation alluded to be experienced in a greater or less degree. Care should be taken not to apply the medicine to an abraded surface, or to a mucous membrane, for fear of dangerous constitutional effects. It is very seldom used, and all its beneficial effects can be obtained from safer and cheaper preparations of aconite. W.

ÆTHEREA.

Ethers.

Ethers are peculiar, fragrant, sweetish, very volatile, and inflammable liquids, generated by the action of acids on alcohol. Their composition varies with the acid employed in their formation. Sometimes this merely acts on the alcohol as a chemical agent, without entering into the composition of the ether generated; in which case the ether consists of water and etherine. In other instances the acid employed unites with water and etherine (the ether just mentioned), or with etherine simply. On the basis of these differences of composition, the medicinal ethers may be divided into three kinds: 1. those consisting of water and etherine; 2. those consisting of an acid, water, and etherine; and 3. those composed of an acid and etherine only. Sulphuric ether is an example of the first kind, hyponitrous ether of the second, and muriatic ether of the third. In medicine, the sulphuric and hyponitrous ethers, and their modifications, are those most commonly employed; though occasionally the acetic and muriatic have been used.

Ethers, from their extreme inflammability, should never be decanted in the vicinity of flame. Hence it is prudent not to pour them out near a lighted candle. They should be kept in accurately stopped bottles in a cool place; otherwise they are liable to considerable loss by evaporation. B.

LIQUOR ÆTHEREUS SULPHURICUS. *Dub. Sulphuric Ethereal Liquor. Unrectified Sulphuric Ether.*

“Take of Rectified Spirit and of Sulphuric Acid, each, *thirty-two ounces*. Pour the Spirit into a glass retort adapted to bearing a sudden heat, and then pour on the acid in a continued stream; mix them gradually, and let twenty fluidounces of the liquor be distilled, with a sudden and sufficiently strong heat, into a receiver kept cold. If *sixteen ounces* of rectified spirit be poured upon the acid remaining in the retort, Sulphuric Ethereal Liquor will again come over by distillation.” *Dub.*

The preparation obtained by this process is sulphuric ether contaminated with alcohol, water, sulphurous acid, and oil of wine. In this state it is proper only for external use. For internal exhibition, it requires to be freed from these impurities, when it becomes a distinct preparation, called rectified sulphuric ether, or, simply, sulphuric ether. This is described in the next article, in which its properties and composition, and the theory of its formation are given.

Off. Prep. Æther Sulphuricus, Dub.

B.

ÆTHER SULPHURICUS. *U. S., Lond., Ed., Dub. Sulphuric Ether. Ether.*

“Take of Alcohol *four pints*; Sulphuric Acid *a pint*; Potassa *six drachms*; Distilled Water *three fluidounces*. To two pints of the Alcohol, in an open vessel, add gradually fourteen fluidounces of the Acid, stirring them frequently. Pour the mixture, while still hot, into a tubulated glass retort, placed upon a sand-bath, and connected by a long adapter with a receiver kept cold by ice or water; then raise the heat quickly until the liquid begins to boil. When about half a pint of ethereal liquid shall have passed over, introduce gradually into the retort the remainder of the Alcohol, previously mixed with two fluidounces of the Acid, taking care that the mixture shall enter in a continuous stream, and in such quantity as shall supply

the place, as nearly as possible, of the liquid which distils over. This may be accomplished by connecting a vessel containing the alcoholic liquid with the retort, by means of a tube provided with a stop-cock to regulate the discharge, and passing nearly to the bottom of the retort, through a cork accurately fitted into the tubulure. When all the Alcohol has been thus added, continue the distillation until about three pints shall have passed over, or until white vapours shall appear in the retort.

“To the product thus obtained add the potassa previously dissolved in the Distilled Water, and shake them frequently. At the end of twenty-four hours, pour off from the alkaline solution the supernatant ether, introduce it into a retort, and, with a gentle heat, distil until two pints shall have passed over, or until the distilled liquid shall have the specific gravity of 0.750.”
U. S.

“Take of Rectified Spirit *fifty fluidounces*; Sulphuric Acid *ten fluidounces*. Pour twelve fluidounces of the Spirit gently over the Acid contained in an open vessel, and then stir them together briskly and thoroughly. Transfer the mixture immediately into a glass matrass connected with a refrigerator, and raise the heat quickly to about 280°. As soon as the ethereal fluid begins to distil over, supply fresh spirit through a tube into the matrass in a continuous stream, and in such quantity as to equal that of the fluid which distils over. This is best accomplished by connecting one end of the tube with a graduated vessel containing the spirit,—passing the other end through a cork fitted into the matrass,—and having a stop-cock on the tube to regulate the discharge. When forty-two [fluid] ounces have distilled over, and the whole spirit has been added, the process may be stopped. Agitate the impure ether with sixteen fluidounces of a saturated solution of muriate of lime, containing about half an ounce of lime recently slaked. When all odour of sulphurous acid has been thus removed, pour off the supernatant liquor, and distil it with a gentle heat so long as the liquid which passes over has a density not above 0.735. More ether of the same strength is then to be obtained from the solution of muriate of lime. From the residuum of both distillations a weaker ether may be obtained in small quantity, which must be rectified by distilling it gently again.” *Ed.*

“Take of Rectified Spirit *three pounds*; Sulphuric Acid *two pounds*; Carbonate of Potassa, previously ignited, *an ounce*. Pour two pounds of the spirit into a glass retort, add the acid to it, and mix. Afterwards place it on sand, and raise the heat so that the liquor may quickly boil, and the Ether pass into a receiver cooled with ice or water. Let the liquor distil until some heavier portion begins to pass over. To the liquor which remains in the retort, after the heat has subsided, add the remainder of the Spirit, that Ether may distil in the same manner. Mix the distilled liquors, then pour off the supernatant portion, and add to it the Carbonate of Potassa, shaking them frequently during an hour. Lastly, distil the Ether from a large retort, and keep it in a stopped vessel.” *Lond.* The specific gravity of this ether is 0.750.

“Take of Sulphuric Ethereal Liquor *twenty fluidounces*; Carbonate of Potassa, dried and powdered, *two drachms*. Mix them, and from a very high retort, distil, by a very gentle heat, twelve fluidounces into a receiver kept cold. The specific gravity of the liquor is 0.765.” *Dub.*

The object of these processes is to obtain a pure sulphuric ether. The Dublin formula is intended to purify the unrectified sulphuric ether (*sulphuric ethereal liquor*), which is officinal only with that College. In the other processes the ether is formed and purified at one operation.

The preparation of sulphuric ether embraces two stages, its generation, and its subsequent rectification to remove impurities. The formulas all agree in obtaining it by the action of sulphuric acid on alcohol. In the U. S. process, which is adopted, with modifications, from that of the French Codex, half the alcohol taken is mixed with seven-eighths of the acid, and while still hot from the reaction, distilled from a glass retort, by a heat quickly applied, into a refrigerated receiver. When the distilled product equals one-fourth of this portion of the alcohol, the remainder of it, mixed with the reserved eighth of the acid, is allowed to enter the retort in a continuous stream, the supply being so regulated as to equal the amount of the liquid which distils over. By a complicated reaction which will be explained presently, the acid converts the alcohol into ether, and were it not that the acid becomes more and more dilute as the process proceeds, it would be able to etherize an unlimited quantity of alcohol. Although the acid, before it becomes too dilute, is capable of determining the decomposition of a certain amount of alcohol, yet it is not expedient to add this amount at once; as a considerable portion of it would distil over with the ether undecomposed. The proper way of proceeding, therefore, is that indicated in the formula; namely, to commence the process with the use of part of the alcohol; and, when the decomposition is fully established, and a portion of ether has distilled, to add the remainder in a gradual manner, so as to replace that which, every moment during the progress of the distillation, is disappearing by its conversion into ether. As, however, the acid in the retort has already become somewhat weaker, it is considered advantageous to mix a small portion of acid with the alcohol which is thus gradually added. When a portion of ether has distilled, equal to about three-fourths of the alcohol employed, or when white vapours appear in the retort, the process is discontinued. These vapours indicate the commencement of a series of reactions different from those which generate the ether.

The *Edinburgh* process for the generation of the ether, is the same, in its general features, with that of the U. S. Pharmacopœia. Less than a fourth of the alcohol is placed in the distilling vessel, previously thoroughly mixed with the *whole* of the acid, which forms one-fifth of the bulk of the alcohol, instead of one-fourth as in the U. S. formula. As soon as the ether begins to distil by a quick heat, the remainder of the alcohol is added in a continuous stream as in the U. S. process, and the distillation is continued until a quantity of ether has come over, equal to somewhat less than six-sevenths of the bulk of all the alcohol. The ether is condensed by means of Liebig's excellent refrigeratory, described and figured at page 772. In this process, it is perceived that no acid is reserved to be mixed with the portion of alcohol gradually added to the distilling vessel, and a much smaller proportion of the spirit is mixed with it at the commencement of the distillation, than in the U. S. formula.

The quantities of the alcohol and acid, in the London formula, are inconveniently taken in weights instead of measures. The improvement of adding the reserved portion of alcohol gradually is not adopted; but the old method is pursued of performing a second distillation with this alcohol, added to the residue in the retort.

The *Dublin* College generates the ether, and rectifies it by separate formulas, giving the crude and rectified product different official names. The process of the College for generating the ether is given in the last article, and, being substantially the same as that of the London College, need not be particularly explained.

The appearance of white vapours in the retort, or the passing over of a heavier portion in the distillation, is the signal for discontinuing the process. If it were continued afterwards, the boiling point would gradually rise, very little ether would be obtained, and at the temperature of 320° there would be generated, in consequence of new reactions, sulphurous acid, oil of wine, olefiant gas, and a large quantity of resino-carbonaceous matter, blackening and rendering thick the residuary liquid; all products which arise from the decomposition of a portion of sulphuric acid, alcohol, and ether. Notwithstanding the process may be stopped in time, yet the ether obtained is contaminated with sulphurous acid, oil of wine, alcohol, and water; and hence its purification becomes necessary. This is conducted in various ways, according to the different Pharmacopœias. The U. S. Pharmacopœia directs for this purpose an aqueous solution of potassa, the London and Dublin Colleges carbonate of potassa, and the Edinburgh a saturated solution of chloride of calcium (muriate of lime), to which a portion of recently slaked lime has been added. In all cases, the crude ether is agitated with the purifying agent, and submitted to a new distillation at a gentle heat, called the *rectification*.

The purifying substances are potassa for sulphurous acid and water, and water for alcohol in the U. S. formula; carbonate of potassa for acid and water in the London and Dublin processes; and lime for acid, and a saturated solution of chloride of calcium for alcohol and water, in the Edinburgh. The Edinburgh substances for purifying are stated by Dr. Christison to be convenient, and to act perfectly and promptly. The chloride of calcium solution, after having been used, yields, on distillation, a further portion of ether of the officinal density; and by concentrating it, filtering while hot, and separating crystals of sulphite of lime which form on cooling, the chloride may be recovered for future operations. In the London and Dublin processes, the ether is distilled from the purifying agent; in the U. S. and Edinburgh, after having been poured off from it. In either case, this distillation, which is performed at a gentle heat, completes the purification; as the ether is the most volatile substance present, and as the process is stopped before the whole of the liquid comes over.

The process for forming ether is conducted with most advantage on a large scale. At Apothecaries' Hall, where the operation is performed in this way, the apparatus employed is thus described by Mr. Brande. It "consists of a leaden still, heated by means of high-pressure steam carried through it in a contorted leaden pipe. A tube enters the upper part of the still, for the purpose of suffering alcohol gradually to run into the acid. The still-head is of pewter, and is connected, by about six feet of tin pipe, with a very capacious condensing-worm, duly cooled by a current of water. The receivers are of pewter, with glass lids, and have a side tube to connect them with the delivering end of the worm-pipe." (*Manual of Chemistry*.)

Properties. Sulphuric ether is a colourless very limpid liquid, of a strong and sweet odour, and hot pungent taste. As prepared for medicinal use, it usually reddens litmus slightly, though this is not a property belonging to the pure substance; but if it reddens litmus strongly, it shows that the ether has been imperfectly prepared or too long kept. When perfectly pure it has the sp. gr. of 0.713, boils at 95° , and is said to freeze at 46° below zero. But according to Dr. J. K. Mitchell, of this city, it is not in the slightest degree affected by this cold. The officinal strength of the U. S. and London ether is 0.750; of the Dublin, 0.765; of the Edinburgh, 0.735, or under. That sold in the shops varies from 0.733 to 0.765. Its sp. gr., as directed by the French Codex, is 0.758. For medicinal purposes, its density should

not be greater than 0.750. According to Dr. Christison, it should not exceed 0.735; because, according to this writer, commercial ether is generally of this density, and may be obtained of such purity without difficulty. It is a very volatile liquid, and when of the sp. gr. 0.720, boils at about 98° , and forms a vapour which has the density of 2.5817. Its extreme volatility causes it to evaporate speedily in the open air, with the production of a considerable degree of cold. When good it evaporates from the hand without leaving a disagreeable odour. Its inflammability is very great, and the products of its combustion are water and carbonic acid. In consequence of this property, the greatest caution should be used not to bring it in the vicinity of flame, as, for example, a lighted candle, for fear of its taking fire. One of the great advantages of using steam as a source of heat is, that it obviates, in a great measure, the danger of its accidental inflammation. When too long kept, it undergoes decomposition, and is converted in part into acetic acid. It dissolves iodine and bromine, and sulphur and phosphorus slightly. The latter substance is generally exhibited in ethereal solution. (See *Phosphorus*.) Its solvent power over corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the organic vegetable alkalies. It does not dissolve potassa and soda, in which respect it differs remarkably from alcohol. Water dissolves a tenth of its volume of ether, and reciprocally ether takes up about the same proportion of water. It unites in all proportions with alcohol.

Impurities and Tests. The impurities found in ether, besides acids and fixed substances, are alcohol, water, and oil of wine. Acids are detected by litmus and removed by agitation with potassa, and fixed substances, by their remaining upon the evaporation of the ether. Alcohol is an admissible impurity in the officinal ethers; for it is contained in the Edinburgh ether, which has the lowest density of them all. If, however, it is present in too large a quantity, the density of the ether will be too high. It may be separated by *washing* the ether as it is called, that is, agitating it with twice its bulk of water, which will unite with the alcohol, forming a heavier stratum after rest, from which the ether may be poured off. The ether, by this treatment, dissolves about a tenth of its bulk of water, from which it may be purified by agitation with fresh burned lime, and subsequent distillation. An easy method for detecting and measuring any alcohol which may be present in ether, is that advised by the Edinburgh College, namely, to agitate it, in a minim measure, with half its volume of concentrated solution of chloride of calcium. This will remove the adulteration, and the reduction of the volume of the ether, when it rises to the surface, will indicate its amount. Oil of wine may be discovered by the ether becoming milky upon being mixed with water.

Composition, and Theory of its Production. Sulphuric ether consists of four eqs. of carbon, five of hydrogen, and one of oxygen, and its empirical formula is C_4H_5O . In volumes it consists of four volumes of carbon vapour, five volumes of hydrogen, and half a volume of oxygen, condensed into one volume of ether vapour. Its proximate constituents are generally considered to be one eq. of etherine and one of water; or in volumes, one volume of etherine vapour and one volume of aqueous vapour, condensed into one volume. This view makes it a *hydrate of etherine* ($C_4H_4 + HO$). The sp. gr. of its vapour, calculated on this constitution in volume, is 2.5817, which is very near 2.586, the number obtained by experiment. By some

chemists, however, the constituents of the etherine, together with the hydrogen of the alleged water, are supposed to form a peculiar hypothetical radical, consisting of C_4H_5 , to which the name of *ethule* has been given. On this view, ether is an *oxide of ethule* ($C_4H_5 + O$). By this statement of the composition of *sulphuric* ether, it is perceived that it contains no *sulphuric* acid, contrary to what its name would imply. The fact is, that it is called *sulphuric* ether, merely in allusion to the agency of the acid usually employed in its preparation; but an identical ether may be obtained by the action of other acids on alcohol. In allusion to the water which it is supposed to contain, it is sometimes called *hydric ether*. For the properties of *etherine* see page 63.

With a view to determine in what manner sulphuric acid acts upon alcohol in order to convert it into ether, it is necessary that a comparison should be instituted between the composition of the two latter. It has already been stated under *Alcohol*, page 62, that this liquid may be viewed as consisting of one eq. of etherine and two of water; and ether, according to one view of its composition, is composed of one eq. of etherine and one of water. It thus appears that alcohol, to be converted into ether, requires only to lose one eq. of water, that is, half the water present in it. On this view etherification would consist merely in the abstraction from alcohol of half the essential water which it contains. The agent in effecting this abstraction is evidently the sulphuric acid, which is known to have a strong affinity for water; but its action is not direct as originally supposed, but intermediate, as was first pointed out by Mr. Hennell. This chemist found that when two eqs. of sulphuric acid and one of alcohol were merely mixed, the acid lost a portion of its saturating power, and a new acid was formed, to which he gave the name of *sulphovinic acid* (the *ethersulphuric acid* of Liebig.) In view of its composition it may be called a bisulphate of alcohol, or, which is the same thing, a bisulphate of ether with one eq. of water, that is, a double sulphate of ether and water. When one eq. of this acid is heated it is decomposed; two eqs. of sulphuric acid with one eq. of water remain in the retort, while one eq. of ether distils over.

If the original proportion of acid and alcohol continued the same throughout the whole of the distillation, all the alcohol would be resolved into water and ether; but, during the progress of the process, the alcohol is constantly diminishing, and of course the relative excess of the acid becoming greater; and at last a point of time arrives when the excess of acid is so great that the generation of ether ceases. As these results depend upon the relative deficiency of the alcohol, while the acid remains but slightly changed in amount, it is easy to understand why it is advantageous to add alcohol gradually to the distilling vessel during the progress of the distillation; for by this addition, the proper proportion of the alcohol to the acid is maintained. But the decomposing power of the acid has its limit; as it becomes at last too dilute to act upon the alcohol, although towards the close of the distillation a considerable portion of water distils over with the ether.

Medical Properties and Uses. Ether is a powerful diffusible stimulant, though transient in its operation. It is also esteemed antispasmodic and narcotic. Its vapour when breathed from a bladder in which a few teaspoonfuls have been put, produces a transient intoxication, resembling that caused by respiring nitrous oxide, but dangerous if carried too far. In some stages of low fevers attended with subsultus tendinum, ether sometimes proves beneficial as a stimulant and antispasmodic. In these cases it is frequently conjoined with laudanum. It is useful also in nervous headache unattended with vascular fulness, some states of hysteria, and generally in nervous and

painful diseases which are unaccompanied by inflammation. In catarrhal dyspnœa, and spasmodic asthma, its vapour may be inhaled with advantage by holding in the mouth a piece of sugar, to which a few drops of ether have been previously added. In nausea it is given as a cordial, and in cramp of the stomach and flatulent colic it sometimes acts with singular efficacy. It is also useful, given alone, or mixed with oil of turpentine, in relieving the pain or spasm caused by the passage of biliary calculi. According to Mr. Brande, a small teaspoonful of ether mixed with a glass of white wine, is often an effectual remedy for allaying the distressing symptoms of seasickness. When externally applied it may act either as a stimulant or refrigerant. If its evaporation be repressed, it operates as a powerful rubefacient, and may even vesicate; but when this is allowed to take place freely, it is refrigerant in consequence of the cold which it produces. In the latter way it is sometimes employed in strangulated hernia, dropped on the tumour and allowed to evaporate. Dr. A. T. Thomson has found ether sometimes to produce immediate relief when dropped into the ear in earache. For external use, the unrectified ether may be employed. The dose of sulphuric ether is from fifty drops to a teaspoonful, to be repeated frequently when the full effect of the remedy is desired. When used habitually the dose must be much larger, to produce a given effect. It may be perfectly incorporated with water or any aqueous mixture, by rubbing it up with spermaceti, employed in the proportion of two grains for each fluidrachm of the ether. The ether and spermaceti are to be rubbed together in a mortar, until the latter is perfectly dissolved; and to the solution thus formed the water or mixture is to be added, while the whole is constantly stirred. The incorporation being finished, the operation is completed by passing the mixture through a piece of muslin to separate the spermaceti. (Durand, *Journ. of the Phil. Col. of Pharm.* iv. 202.)

Sulphuric ether is used in the preparation of Morphine Acetas, *U. S.*

Off. Prep. Spiritus Ætheris Sulphurici, *Ed.*; Spiritus Ætheris Sulphurici Compositus, *U. S., Lond.* B.

OLEUM ÆTHEREUM. *U. S., Lond.* LIQUOR ÆTHEREUS OLEOSUS. *Dub.* *Ethereal Oil.* *Heavy Oil of Wine.*

"Take of Alcohol *two pints*; Sulphuric Acid *three pints*; Solution of Potassa *half a fluidounce*; Distilled Water *a fluidounce*. Mix the Acid cautiously with the Alcohol, allow the mixture to stand twelve hours, then pour it into a large glass retort, to which a receiver kept cool by ice or water is adapted, and distil by means of a sand-bath until a black froth rises, when the retort is to be removed immediately from the sand-bath. Separate the lighter supernatant liquid in the receiver from the heavier, and expose it to the air for a day; then add to it the Solution of Potassa previously mixed with the Distilled Water, and shake them together. Lastly, separate the Ethereal Oil as soon as it shall have subsided. The specific gravity of this liquid is 1.096." *U. S.*

"Take of Rectified Spirit *two pounds*; Sulphuric Acid *four pounds*; Solution of Potassa, Distilled Water, each, *a fluidounce* [Imperial measure], or as much as may be sufficient. Mix the Acid cautiously with the Spirit. Let the liquor distil until a black froth arises; then immediately remove the retort from the fire. Separate the lighter supernatant liquor from the heavier one, and expose the former to the air for a day. Add to it the Solution of Potassa first mixed with Water, and shake them together. Lastly, when sufficiently washed, separate the Ethereal Oil which subsides." *Lond.* The specific gravity of this oil is 1.05.

“Take what remains in the retort after the distillation of Sulphuric Ether. Distil down to one-half with a moderate heat.” *Dub.*

When alcohol is distilled with a large excess of sulphuric acid, the same products are generated as those mentioned in the last article as being formed towards the close of the distillation of ether. These were stated to be sulphurous acid, oil of wine, olefiant gas, and carbonaceous matter. In the *U. S.* process such an excess of sulphuric acid is employed, for the purpose of obtaining the oil. The product of the distillation is in two layers, a heavier one, consisting of water holding sulphurous acid in solution, and a lighter, formed of ether containing the oil of wine. The lighter liquid is separated and exposed for twenty-four hours to the air, in order to dissipate the ether by evaporation; and the oil, which is left, is shaken with a solution of potassa to deprive it of all traces of water or acid; after which, as soon as it subsides, it is to be separated. The *London* process is substantially the same as that of the *U. S. Pharmacopœia*. The differences are, that the *London* College omits to direct a prolonged contact between the alcohol and acid, and dispenses with a refrigerated receiver. The *Dublin* formula is altogether defective. By distilling the residue of the sulphuric ether process “down to one-half with a moderate heat,” the oil of wine is no doubt obtained; but it is mixed with various substances, for its separation from which no directions are given in the formula.

The nature and mode of formation of heavy oil of wine are not well understood. It has been explained in the preceding article, that, in the early stage of the distillation of a mixture of sulphuric acid and alcohol, sulphovinic acid, or double sulphate of ether and water is formed. During its progress this is decomposed so as to yield ether. When, however, the alcohol is distilled with a large excess of sulphuric acid, this same compound is decomposed so as to form a small quantity of the heavy oil of wine, now considered to be a double sulphate of ether and etherine, having the formula $C_4H_5O,SO_3 + C_4H_4,SO_3$. It is conceived to be generated from two eqs. of sulphovinic acid (double sulphate of ether and water), which are resolved into one eq. of the oil, two of sulphuric acid, and three of water. When the heavy oil of wine is gently heated with four parts of water, it is resolved into sulphovinic acid which dissolves, and etherine which floats on the surface, and which, when thus obtained in a separate state, is called *etherole* or *light oil of wine*. This, when left for a long time at a low temperature, deposits crystals, called *oil of wine camphor*, *concrete oil of wine*, and sometimes, in disregard of precision of nomenclature, etherine.

Properties. The *official ethereal oil* (*heavy oil of wine*) is a yellowish liquid, possessing an oleaginous consistency, a peculiar and slightly acid odour, and rather sharp and bitter taste. It boils at 540° . Its sp. gr. is, according to the *U. S. Pharmacopœia*, 1.096, according to the *London College*, after Mr. Hennell's results, 1.05. By Dumas and Serullas its density is stated to be as high as 1.133, which is probably the more correct number for the *pure* oil. It is sparingly soluble in water, but readily so in alcohol and ether. It is devoid of acid reaction, the sulphuric acid present in it being completely neutralized by the ether and etherine united with it. The sulphuric acid present is not precipitated by the usual reagents, because they furnish a second base, which, replacing the etherine, forms one of the double salts of sulphovinic acid, all of which are soluble in water and hydrous alcohol. The process by which it is formed yields but a small product, being only about one part in weight to thirty-one of the alcohol employed, even when performed on the large scale; and when conducted

on the small scale of the Pharmacopœias, the product is only one part of the oil to about seventy-five of the alcohol. The *light oil of wine* is a colourless oily liquid, having an aromatic odour. Its sp. gr. is between 0.917 and 0.920, boiling point 536° , and freezing point 31° below zero. It communicates a greasy stain to paper. The *concrete oil* crystallizes in long, transparent, brilliant, tasteless prisms, soluble in alcohol and ether, insoluble in water, fusible at 230° , boiling at 500° , and having the sp. gr. of 0.980.

Composition. The *official oil of wine* has already been stated to be a double sulphate of ether and etherine. If the elements of one eq. of water be added to its constituents, it becomes a *sulphate of ether*, and Dumas appears to consider this to be its true composition. The *light oil of wine*, the etherine in the above compound, is of course composed of C_4H_4 . The *concrete oil* is polymeric with this. The discrepancies in the densities given by different authors for the official oil of wine, no doubt arise from its containing more or less of this concrete oil, which would necessarily lower its specific gravity.

The official oil is not used in medicine in a separate state, but forms an ingredient of the compound spirit of sulphuric ether, or Hoffmann's anodyne.

"Take of Sulphuric Ether *half a pint*; Alcohol *a pint*; Ethereal Oil *three fluidrachms*. Mix them." *U. S.*

"Take of Sulphuric Ether *eight fluidounces*; Rectified Spirit *sixteen fluidounces*; Ethereal Oil *three fluidrachms*. Mix them." *Lond.*

Compound spirit of sulphuric ether is a volatile liquid, having a burning, slightly sweetish taste, and the peculiar odour of ethereal oil. Its sp. gr. is 0.816, according to the U. S. Pharmacopœia. When pure it is wholly volatilized by heat and devoid of acid reaction. It becomes milky on being mixed with water, owing to the precipitation of the ethereal oil; but this change does not prove its goodness, as the same property may be given to the spirit of sulphuric ether, by the addition of various oils. One of the authors has been informed by Dr. Hotchkiss, that castor oil is sometimes added to the latter preparation, in order to give it the character of Hoffmann's anodyne, of becoming milky when diluted with water. This sophistication may be detected, as ascertained by Mr. Wm. Procter, Jun., by mixing the suspected preparation with water, drawing a piece of paper over the surface of the liquid to absorb the oily globules, and exposing the paper to heat. If the globules are castor oil, the greasy stain will be permanent, if oil of wine, the stain will disappear.

Medical Properties. This preparation is intended as a substitute for the

anodyne liquor of Hoffmann, which it closely resembles. In the last edition of the U. S. Pharmacopœia it has been made exactly after the London formula. In addition to the stimulating and antispasmodic qualities of the ether which it contains, it possesses anodyne properties, highly useful in nervous irritation, and want of sleep from this cause. These additional virtues it derives from the officinal or heavy oil of wine, which is a more important substance than is generally supposed. Mr. Brande supposes that the only effect of it, in the preparation under notice, is to alter the flavour of the sulphuric ether. In this opinion he is certainly in error. Dr. Hare, in his Chemical Compendium, reports the opinion of Drs. Physick and Dewees in favour of the efficacy of the officinal oil of wine, dissolved in alcohol, in certain disturbed states of the system, as a tranquillizing and anodyne remedy. Such indeed are the generally admitted effects of Hoffmann's anodyne, when made with a due admixture of the ethereal oil; but a preparation very deficient in oil is often improperly sold for it, which, instead of milky, becomes merely opalescent when mixed with water. It is on many occasions a useful adjunct to laudanum, to prevent the nausea which is excited by the latter in certain habits. Its dose is from half a fluidrachm to two fluidrachms, given in water sweetened with sugar. B.

ÆTHER NITROSUS. *Dub. Nitrous Ether. Nitric Ether. Hyponitrous Ether.*

“Take of Purified Nitrate of Potassa, dried and coarsely powdered, *a pound and a half*; Sulphuric Acid *a pound*; Rectified Spirit *nineteen fluid-ounces*. Put the Nitrate of Potassa into a tubulated retort, placed in a bath of cold water, and pour on it, by degrees and at intervals, the Sulphuric Acid and Spirit, previously mixed, and cooled after their mixture. Without almost any external heat, or at most a very gentle one (as of warm water added to the bath), the ethereal liquor will begin to distil without the application of fire. In a short time, the heat in the retort will increase spontaneously, and a considerable ebullition will take place, which must be moderated by reducing the temperature of the bath with cold water. The receiver must also be kept cold with water or snow, and furnished with a proper apparatus for transmitting the highly elastic vapour (bursting from the mixture with great violence if the heat be too much increased) through a pound of Rectified Spirit contained in a cooled bottle.

“The ethereal liquor, thus spontaneously distilled, is to be received into a bottle with a ground glass stopper; and then must be added by degrees (closing the bottle after each addition) as much very dry and powdered carbonate of potassa as will suffice to saturate the excess of acid, using litmus as the test. This is effected by the addition of about a drachm of the salt. In a short time the Nitrous Ether will rise to the surface, and is to be separated by means of a funnel.

“If the ether be required very pure, distil it again to one-half, from a water-bath at a temperature of 140°. Its specific gravity is 0.900.” *Dub.*

The Dublin is the only Pharmacopœia, commented on in this work, which embraces among its preparations hyponitrous ether (called also *nitrous* and *nitric ether*) under a distinct name; but the Edinburgh College prepares it as the first step in the process for sweet spirit of nitre. The mutual reaction of nitric acid and alcohol is so violent, that the formation of this ether has justly been regarded as a process of difficulty. The method adopted by the Dublin College was contrived by Wolfe, and is commended by Pelletier, as well adapted for obtaining this ether with facility and safety. The alcohol is not mixed directly with nitric acid, but with the materials

necessary for generating it. Upon the addition of the mixture of sulphuric acid and alcohol to the nitre, this salt is decomposed, and the disengaged nitric acid gradually reacts upon the alcohol, and generates the ether in question. The heat evolved upon mixing the materials is so considerable, that the application of extraneous heat is unnecessary and even hazardous. Indeed, as the action advances, the temperature of the mixture must be moderated by the application of cold water. The violent action arises from the vast quantity of gases and vapours suddenly given off. These are nitrogen, nitrous and nitric oxides, carbonic acid, and the vapours of water, nitrous acid, and hyponitrous ether itself. Notwithstanding the cold employed, a portion of the ether escapes condensation in the receiver, and hence the Dublin College, to save this portion, directs a cooled bottle to be connected with it, containing a pound of alcohol, into which the uncondensed ether is allowed to pass. The alcohol thus impregnated is subsequently employed in the Dublin formula for sweet spirit of nitre. (See *Spiritus Ætheris Nitrici*.) The ether condensed in the receiver is not pure, but contains a little nitrous, nitric, and acetic acids. To remove these, the ethereal product is shaken with carbonate of potassa, which has the effect of saturating them.

Hyponitrous ether is prepared by Thenard according to the following process. Equal weights of alcohol and nitric acid, contained in a retort having a capacity double their volume, are distilled, by a moderate heat, into a Wolfe's apparatus of five bottles, the first of which is empty, and the four others half filled with saturated brine. Each bottle is placed in an earthen pan containing a mixture of ice and salt. The apparatus being thus arranged, a few live coals are placed under the retort, whereupon the liquid enters quickly into ebullition. The fire must then be immediately withdrawn, and the ebullition moderated, by allowing some water pressed from a sponge to flow over the retort. The process is terminated when the spontaneous ebullition ceases; at which time the liquid in the retort forms a little more than a third of the quantity of alcohol and acid employed. In the first bottle, a large quantity of yellow liquid will be found, consisting of much weak alcohol, of ether, and nitrous, nitric, and acetic acids; in the second, a pretty thick stratum of ether, containing a little acid and alcohol, and swimming on the surface of the brine; in the third, a very thin stratum of the same nature as that in the second, and so on for the rest. The several layers of ether are then separated by means of a funnel, mixed together, and redistilled, with a moderate heat, into a refrigerated receiver. The first product is the ether, which, to be perfectly pure and devoid of acidity, must be allowed to remain in a bottle for half an hour, in contact with powdered lime. From 500 parts of alcohol and 500 of acid, Thenard obtained 100 of excellent ether.

Liebig recommends the following process for obtaining this ether in a state of purity. One part of starch and ten of nitric acid (sp. gr. 1.3) are introduced into a capacious retort, which is connected with a two-necked bottle by means of a wide tube two or three feet long, bent at right angles, and reaching to its bottom. This bottle contains a mixture of two parts of alcohol of 85 per cent. and one of water, and is surrounded with cold water. The second neck is connected, by means of a long and wide tube, with a good cooling apparatus. (See page 772.) The retort is heated by a water-bath, and, by the reaction of the starch and nitric acid, pure hyponitrous acid is disengaged, which, passing through the alcohol, forms with its ether hyponitrous ether, which distils in a continuous stream. It is then freed from alcohol by means of water, and from water by standing over chloride

of calcium. This process is stated to be very productive. (*Turner's Chemistry*, 7th Ed. p. 849.)

Dr. Hare has devised an ingenious process for obtaining this ether, in which he avails himself of a hyponitrite ready formed. When nitre is exposed to heat, as in the process for obtaining oxygen from it, about one-third is converted into hyponitrite of potassa. This may be obtained separate by crystallizing the nitrate from it. Fourteen parts of the hyponitrite, thus procured, are dissolved in seven parts of water, and mixed, in a tubulated retort, with eight parts of alcohol. The beak of the retort is made tapering and bent downwards, and enters a tube, occupying the axis and descending through the neck of an inverted bell glass, so as to terminate within a tall vial. Both the tube and vial are kept cold by ice and water. Seven parts of sulphuric acid, diluted with its weight of water, are gradually added to the retort, and the ether is distilled by means of a water-bath, kept blood-warm. (*Trans. of the Amer. Phil. Soc.*, vii. 277; also *Proceedings of the Society*, ii. 143, Jan. 1842.)

Theory of the Production of Hyponitrous Ether, &c. In the process of Dr. Hare, the hyponitrous acid, ready formed, is liberated from a hyponitrite in contact with alcohol, with the ether of which the acid unites. In Liebig's process hyponitrous acid is formed by the agency of starch, by which two eqs. of oxygen are detached from each eq. of nitric acid, and is passed into alcohol contained in a separate vessel. When nitric acid is mixed directly with the alcohol, the reaction is different. Here one eq. of nitric acid, by reacting with one eq. of alcohol, forms one eq. of hyponitrous acid, one eq. of aldehyd, and two eqs. of water. Thus $\text{NO}_5 + \text{C}_4\text{H}_6\text{O}_2 = \text{NO}_3 + \text{C}_4\text{H}_4\text{O}_2 + 2\text{HO}$. The hyponitrous acid, as soon as formed, reacts with a second eq. of alcohol, so as to form one eq. of hyponitrous ether, with separation of one eq. of water. It has, however, been shown by Dr. Golding Bird that, when an excess of alcohol is used, *oxalhydric* (*saccharic*) acid is first formed, and that when the formation of the hyponitrous ether has nearly ceased, aldehyd makes its appearance in the distilled product, and simultaneously oxalic acid in the contents of the retort, before which time the latter cannot be discovered. All these products result from the oxidizing action of the nitric acid upon the alcohol, increasing the proportion of oxygen in the substances formed, either by removing hydrogen, or by abstracting this element and adding directly to the oxygen at the same time. The reader who may wish to pursue this subject, is referred to the interesting paper of Dr. Bird, contained in the *Lond. & Ed. Phil. Mag.* xiv. 324, for May 1839.

Properties. Pure hyponitrous ether is pale yellow, has the smell of apples and Hungary wines, boils at 62° (below 65° Hare), and has the sp. gr. of 0.947 at 60° . The density of its vapour is 2.627. Litmus is not affected by it. When mixed with an alcoholic solution of potassa, hyponitrite of potassa and alcohol are formed, without producing a brown colour, showing the absence of aldehyd. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue. The *impure* ether obtained by the ordinary processes boils at 70° , and has the density of 0.886 at 40° . The officinal specific gravities of it are 0.900 *Dub.*, 0.899 *Ed.* (See the next article for the Edinburgh ether.) Mixed with an alcoholic solution of potassa, it becomes dark brown, with production of aldehyd resin. This discoloration shows the presence of aldehyd. When kept it becomes acid in a short time, as shown by litmus, and nitric oxide is given off, which often causes the bursting of the bottle. Its tendency to become acid is rendered greater by the action of the air, and depends on the absorption of oxy-

gen by the aldehyd, which thereby becomes acetic acid. These facts show the propriety of preserving this ether in small, strong bottles, kept full and in a cool place. Hyponitrous ether consists, as already explained, of one eq. of hyponitrous acid and one of ether, and its formula is $C_4H_5O + NO_3$. It is, therefore, improperly called *nitrous* and *nitric* ether. In its pure or concentrated state it is never used in medicine. Diluted with alcohol (rectified spirit) it forms the spirit of nitric ether, or sweet spirit of nitre, described in the next article.

B.

SPIRITUS ÆTHERIS NITRICI. *U.S., Lond., Ed.* SPIRITUS ÆTHEREUS NITROSUS. *Dub.* SPIRITUS NITRI DULCIS. *Spirit of Nitric Ether. Sweet Spirit of Nitre.*

“Take of Nitrate of Potassa, in coarse powder, *two pounds*; Sulphuric Acid *a pound and a half*; Alcohol *nine pints and a half*; Diluted Alcohol *a pint*; Carbonate of Potassa *an ounce*. Mix the Nitrate of Potassa and the Alcohol in a large glass retort, and, having gradually poured in the Acid, digest with a gentle heat for two hours; then raise the heat and distil a gallon. To the distilled liquor add the Diluted Alcohol and Carbonate of Potassa, and again distil a gallon.” *U.S.*

“Take of Rectified Spirit *three pounds*; Nitric Acid *four ounces*. Add the Acid gradually to the Spirit and mix them; then distil thirty-two fluidounces [Imperial measure].” *Lond.*

“Take of Rectified Spirit *two pints and six fluidounces* [Imperial measure]; Pure Nitric Acid (D. 1.500) *seven fluidounces* [Imp. meas.]. Put fifteen fluidounces of the Spirit, with a little clean sand, into a two-pint matrass, fitted with a cork, through which are passed a safety-tube terminating an inch above the Spirit, and another tube leading to a refrigerator. The safety-tube being filled with Pure Nitric Acid, add through it gradually three fluidounces and a half of the acid. When the ebullition which slowly rises is nearly over, add the rest of the acid gradually, half a fluidounce at a time, waiting till the ebullition caused by each portion is nearly over before adding more, and cooling the refrigerator with a stream of water, iced in summer. The ether thus distilled over, being received in a bottle, is to be agitated first with a little milk of lime, till it ceases to redden litmus paper, and then with half its volume of concentrated solution of muriate of lime. The pure hyponitrous ether thus obtained, which should have a density of 0.899, is then to be mixed with the remainder of the Rectified Spirit, or exactly four times its volume.

“Spirit of Nitric Ether ought not to be kept long, as it always undergoes decomposition, and becomes at length strongly acid. Its density by this process is 0.847.” *Ed.*

“Add to the matter which remains after the distillation of Nitrous Ether, the Rectified Spirit employed in that operation for condensing the elastic vapour, and distil till the residuum be dry, with the *superior* heat of a water-bath. Mix the distilled liquor with the alkaline liquor which remains after the separation of the Nitrous Ether, and add, moreover, as much well dried Carbonate of Potassa as shall be sufficient to saturate the predominant acid. This is made evident by the test of litmus. Lastly, distil as long as any drops come over by the *medium* heat of a water-bath. The specific gravity of this liquor is 0.850.

“Nitrous Ethereal Spirit may also be prepared by adding gradually *two ounces* of Nitric Acid to *a pint* of Rectified Spirit, and distilling twelve ounces with a proper apparatus and the application of a gentle heat.” *Dub.*

The official spirit of nitric ether is a mixture, in variable proportions,

of hyponitrous ether and alcohol (rectified spirit). Hyponitrous ether is always generated by the reaction of nitric acid and alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid. When the materials for forming the ether contain an excess of alcohol, this distils over with the ether, and forms the preparation under consideration.

The processes of the Pharmacopœias differ considerably. The U. S and Dublin Pharmacopœias obtain the requisite nitric acid by using the materials for generating it; while the London and Edinburgh Colleges mix the acid ready formed with the alcohol. The London and Edinburgh processes, however, differ in one important particular, namely, that while the London College distils the nitric acid with an excess of alcohol, which comes over in large proportion with the ether, forming, at once, the sweet spirit of nitre; the Edinburgh College forms a concentrated, almost pure, hyponitrous acid in the distillation, and dilutes it with a determinate quantity of alcohol.

The *United States* formula is modeled after a recipe communicated by Mr. John Carter, manufacturing chemist, to the Philadelphia College of Pharmacy, and recommended for adoption by a committee of that body. It is in fact the Dublin process for obtaining hyponitrous ether, explained in the preceding article, with the use of alcohol in excess. The nitre and alcohol being mixed in the retort, the sulphuric acid is gradually added, and a gentle heat applied. Nitric acid is set free, and by reacting with a part of the alcohol produces the hyponitrous ether, as explained in the last article. Upon the subsequent increase of the heat, the ether and the remainder of the alcohol distil over as the sweet spirit of nitre. The distilled product, however, contains some acid, and hence is rectified by a distillation from carbonate of potassa. The diluted alcohol is added before commencing this distillation, to enable the operator to obtain a quantity of distilled product equal to that procured at first, without distilling to dryness, which would endanger the production of empyreuma. The alcohol and sulphuric acid are successively added to the nitre, and not previously mixed; as by the latter plan, the sulphuric acid would be converted in part into sulphovinic acid, and the risk would be run of generating some sulphuric ether. The retort should be of such a capacity as to be capable of holding twice the amount of the materials employed.

The above process, as conducted by Mr. Carter on a large scale, is performed in a copper still of about twenty gallons capacity, and furnished with a pewter head and worm. The materials for the first distillation are 18 pounds of purified nitre, 12 gallons of alcohol of 34° Baumé (0.847), and 12 pounds of sulphuric acid; and 10 gallons are drawn off. The distilled product is then mixed with a gallon of diluted alcohol, and rectified by a new distillation from lime or a carbonated alkali; the same quantity being distilled as at first. When large quantities of this preparation are thus obtained, the several portions require to be mixed in a large glass vessel, to render the whole of uniform strength; as the portion which first comes over in the rectification is strongest in hyponitrous ether. Previous to the redistillation, the head and worm must be washed thoroughly with water, to remove a little acid which comes over in the first distillation. (*Journ. of the Phil. Col. of Pharm.* i. 308.)

A similar process to the above for making sweet spirit of nitre, is adopted in the principal laboratories of Philadelphia. As the use of metallic vessels is attended with some risk, it would be an improvement in the above process, if an earthenware still and worm were employed, as is done at Apothe-

caries' Hall, London; the still being heated by the slow application of steam to its outer surface.

In order to understand the process of the *Dublin* College for preparing sweet spirit of nitre, it will be necessary to revert to their formula for obtaining hyponitrous ether, explained in the last article. The residue of this process consists of sulphate of potassa, free nitric acid not consumed in the generation of the ether, and certain products resulting from the oxidation of the alcohol by the nitric acid, as mentioned in the last article. To this residue is added the pound of alcohol, which had been employed in the process for the purpose of absorbing the ether which escapes condensation in the receiver. Of course, after this addition, all the conditions are fulfilled which are necessary for the generation of sweet spirit of nitre, namely, nitric acid in contact with more alcohol than is necessary to form ether. Accordingly, upon distillation, the ether comes over mixed with a certain proportion of alcohol, forming the sweet spirit of nitre. But at the same time, a portion of acid is distilled over, to separate which the product is redistilled from an alkaline carbonate at a *medium* heat (between 100° and 200°) as long as any drops come over. To save the alkaline solution used in purifying the ether described in the last article, it is directed to be applied, as far as it will go, to the purpose of saturating the free acid of this preparation.

From the explanations here and previously given, it is obvious that the formulæ for hyponitrous ether and sweet spirit of nitre of the *Dublin* College form in fact but one process; and whenever it is desirable to obtain nitric ether, it is no doubt expedient to use the residue and part of the products of the process, for procuring sweet spirit of nitre, provided the latter preparation can be obtained from them of good quality. But when it is recollected that the residue is loaded with newly-formed acids, and that the quantity of free nitric acid in it cannot be estimated, it may be well doubted whether this process of the *Dublin* College is an eligible one. As hyponitrous acid is never employed in medicine in a pure state, and has very few uses, it is an objection to this formula that it requires the preparation of another substance which may not be wanted. It is, no doubt, on this account that the College has appended to this process for sweet spirit of nitre, another formula, similar to that of the *London* College, by which it may be obtained independently of any other product.

In the *London* process, nitric acid, ready formed, is mixed with the alcohol; the proportion of acid to the spirit being as 1 to 9 in weight. The proportion of nitric acid to the alcohol in the U. S. formula, is nearly the same as that in the *London* process, if we suppose that the nitre, by its decomposition, yields a pound and a quarter of acid, which is about the quantity obtained in practice. This coincidence may be assumed with the greater confidence, as the preparation obtained by the two processes has the same specific gravity. The proportion of sweet spirit of nitre drawn off to the alcohol employed is a little over two-thirds in the *London* formula, and five-sixths in that of the U. S. Pharmacopœia. When the distillation is pushed too far, the product is high-coloured, specifically heavier than it should be, very acid so as to act strongly on litmus paper, decomposes the alkaline carbonates with effervescence, and contains aldehyd, which gives it a pungent odour. (*Dr. Golding Bird*). The impurities arising from a distillation carried too far are, according to *Dr. Bird*, entirely avoided by following the directions of the *London* Pharmacopœia. The residue of the process, if further distilled, will yield a small additional portion of sweet nitre, nearly pure, of higher specific gravity than the officinal portion; but, afterwards, on continuing the process, the hyponitrous ether ceases to come over, and

about the same time aldehyd appears in the distilled product, and in the residue oxalic acid, which seems to replace the oxalhydric acid, formed at an earlier stage of the reaction. (See last article.) Admitting Dr. Bird's results, it is probable that the sweet spirit of nitre which comes over in the first distillation of the U. S. process will contain aldehyd; as one-fourth more of liquid is drawn over than is distilled in the London process. Supposing this to be the case, it is presumable that it would be separated, together with any contaminating acid, by the second distillation with carbonate of potassa.

The *Edinburgh* process for sweet spirit of nitre, consists of two steps; first, the formation of hyponitrous ether, and, secondly, its dilution with four times its volume of alcohol. Dr. Christison, commenting on this process, states that it may be conducted with safety and despatch, when the precautions are attended to which are enjoined by the *Edinburgh College*. The conditions for success are to add no more spirit at first than what is necessary to commence the action; to wait until the ebullition thus arising shall cease; to add the rest of the acid in small successive portions; to let the acid drop from the height of about an inch into the spirit; to have some clean sand in the bottom of the matrass; and to employ a refrigeratory, such as that figured at *page 772*. Should the ebullition increase too rapidly, it may be repressed by blowing cool air across the matrass. The presence of the sand prevents the dangerous succussions arising from the sudden liberation of ethereal vapour. The ethereal product is first agitated with milk of lime to separate acid, and then with half its volume of a concentrated solution of chloride of calcium, to remove water and alcohol. The density given for this hyponitrous ether is 0.899, which is lower than that of the pure ether. The last step in the process is to mix this ether with the prescribed quantity of alcohol, which gives a sweet spirit of nitre of the density of 0.847. The hyponitrous ether of this process may be presumed to measure, on an average, $7\frac{3}{4}$ fluidounces, and, consequently, the sweet spirit of nitre obtained from it, $38\frac{3}{4}$ fluidounces. The degree of dilution was fixed, so as to make it conform in ethereal strength with the same preparation of the former *Edinburgh Pharmacopœia*. The preparation is intended to contain one-fifth of its volume of ether, and is probably twice or thrice as strong as the sweet spirit of nitre of the U. S. and London *Pharmacopœias*. For making this preparation, Dr. Christison prefers the present plan of the *Edinburgh College*, of diluting the pure ether to a determinate degree, on the ground that it secures a pure and uniform preparation. Many years ago the same plan was proposed by Dr. Hare.

Properties. Spirit of nitric ether is a colourless volatile liquid, of a fragrant ethereal odour, and pungent, aromatic, sweetish acidulous taste. The *Edinburgh* preparation is yellow. If perfectly pure it is devoid of acid reaction, but it generally reddens litmus slightly. Its official sp. gr. is 0.834 *U. S.*, *Lond.*; 0.847 *Ed.*; and 0.850 *Dub.* High density is not necessarily an index of deficient strength, as it may arise, as in the *Edinburgh* preparation, from containing a large proportion of the pure ether. If heated by means of a water-bath, the U. S. sweet spirit of nitre begins to boil at 160°. It mixes with water and alcohol in all proportions. It is very inflammable, burning with a whitish flame, and, when evaporated, produces much cold.

Impurities and Tests. Sweet spirit of nitre, when the product of a distillation too long continued, at first contains aldehyd, which afterwards becomes acetic acid by the absorption of oxygen—rapidly if the preparation be insecurely kept. The presence of aldehyd may be detected by its imparting a

pungent odour and acrid flavour, and by the preparation containing it assuming a yellow tint on the addition of a weak solution of potassa, owing to the formation of aldehyd resin. It is probable that this impurity is not often in large amount, being replaced by its product the acetic acid. As aldehyd appears to be the chief source of impurity in sweet spirit of nitre, and as it is detected by producing a characteristic colour with a solution of potassa, it would seem easy to make this test available as an index when the distillation should be discontinued. For if the distilled product were made to pass through a small portion of this alkaline solution, it would probably give indications of the first appearance of aldehyd, and thus enable the operator to stop the distillation in time. Acetic acid, as well as any others (usually nitrogen acids) that may happen to be present, may be discovered by the taste, by their acting on litmus strongly, and by their decomposing the alkaline carbonates or bicarbonates with effervescence. These acids often operate injuriously by their chemical reactions with other substances, when associated in mixtures. Thus they liberate iodine from iodide of potassium, gradually decolorize infusion of roses, and, in the compound mixture of iron, hasten the conversion of the protoxide into the sesquioxide of iron. To obviate these effects, Mr. Harvey, of Leeds, keeps the sweet spirit of nitre standing on crystals of bicarbonate of potassa, and states that if the preparation be of full strength, no appreciable portion of the alkali will be dissolved. (*Pharm. Journ. and Trans. Jan. 1842.*) A deep olive colour being produced with the sulphate of protoxide of iron, shows the presence of a nitrogen oxide or acid, and a blue tint with tincture of guaiacum, passing through various shades of green, a nitrogen acid.

Other impurities which are often fraudulently added to sweet spirit of nitre, are water and alcohol. These may be detected in the Edinburgh preparation, as stated by the College, by agitating it with twice its volume of a concentrated solution of chloride of calcium. If the sweet spirit of nitre be of full strength, 12 per cent. of ether will slowly separate, which is twelve-twentieths of the quantity present. The test acts by taking up the alcohol and water; and if less ether separate, it shows the presence of too much of the former substances. This test is hardly applicable to the U. S. and London preparation, which is much weaker than the Edinburgh. Dr. Christison states that the London sweet spirit of nitre, when subjected to this test, has never yielded in his trials more than four per cent. of ether. Sometimes it yields none. Specific gravity is no criterion of the goodness of the preparation as obtained by any formula. The addition of water will raise its density; so will the addition of hyponitrous ether. A high density, in connection with deficient ethereal qualities, would, of course, show the presence of free acids, an excess of water, or both. A specific gravity lower than the U. S. and London standard, would probably indicate the presence of alcohol stronger than it should be, which might be either in proper amount or in too large proportion.

The fraudulent dilution of sweet spirit of nitre with alcohol and water is a great evil, considering the extensive use of the medicine, and its valuable remedial powers when pure. We have been informed on good authority, that it is variously diluted, according to the views of the vender, with twice, thrice, and even four times its weight of alcohol and water. In some shops it is stated that a strong and a weak preparation are kept, to suit the views of customers as to price. Some of the wholesale druggists are in the habit of diluting it, either upon the plea that the physician's prescriptions are written in view of the use of a weak preparation, or for the purpose of affording it at a low price. All these evils would be corrected, if the

different manufacturing chemists in the Union would comply with the recommendation of the Philadelphia College of Pharmacy, and adopt for preparing it the formula of the United States Pharmacopœia. A uniform preparation being in this way furnished to the druggists, all that would be necessary on their part, would be carefully to abstain from weakening it by the admixture of alcohol and water.

Medical Properties and Uses. Sweet spirit of nitre is diaphoretic, diuretic, and antispasmodic. It is deservedly much esteemed as a medicine, and is extensively employed in febrile affections, either alone, or in conjunction with tartar emetic, for the purpose of promoting the secretions, especially those of sweat and urine. It often proves a grateful stimulus to the stomach, relieving nausea and removing flatulence, and not unfrequently allays restlessness and promotes sleep. On account of its tendency to the kidneys, it is often conjoined with other diuretics, such as squill, digitalis, acetate of potassa, nitre, &c., for the purpose of promoting their action in dropsical complaints. The late Dr. Duncan praised a combination of it with a small portion of aromatic spirit of ammonia, as eminently diaphoretic and diuretic, and well suited to certain states of febrile disease. The dose is about a teaspoonful, given every two or three hours in a portion of water. When used as a diuretic, it should be given in larger doses. B.

ALCOHOL.

Preparations of Alcohol.

ALCOHOL DILUTUM. U.S. SPIRITUS TENUIOR. *Lond., Ed., Dub. Diluted Alcohol. Proof Spirit.*

“Take of Alcohol, Distilled Water, each, *a pint*. Mix them. The specific gravity of Diluted Alcohol is 0.935.” U. S.

“Take of Rectified Spirit *two pints* [Imperial measure]; Distilled Water *a pint* [Imp. meas.]. Mix them. The density of the product should be 0.912.” *Ed.*

The London and Dublin Colleges have placed diluted alcohol or proof spirit in the list of the *Materia Medica*. The *Edinburgh* College has ordered the strongest diluted alcohol, its density being 0.912, which is 7 over proof. It contains 52 per cent. of absolute alcohol, and is considerably stronger than the corresponding spirit of the former *Edinburgh Pharmacopœia*. The *London* College directs its sp. gr. to be 0.920. When of this strength, it contains 49 per cent. of pure alcohol, and may be formed by mixing five measures of their rectified spirit with three of distilled water at the temperature of 62°. In the *Dublin Pharmacopœia*, it is ordered of the sp. gr. 0.919, and the statement is made in a note, that spirit of almost the same specific gravity may be formed by mixing five and a quarter measures of the rectified spirit of that work with three of distilled water. Such a spirit will contain a little more than 49 per cent. of absolute alcohol, and will agree very nearly in strength with the corresponding spirit of the *London* College. The diluted alcohol of the U. S. Pharmacopœia has the sp. gr. 0.935, and contains only 42 per cent. of absolute alcohol. It, therefore, forms the weakest official proof spirit.

Medical and Pharmaceutical Uses. The medicinal effects of alcohol in a diluted and modified state, as it exists in brandy and other ardent spirits, have been detailed under other heads. (See *Alcohol* and *Vinum*.) As a pure diluted spirit, however, consisting solely of alcohol and water in determinate proportions, its use is exclusively pharmaceutical. It is employed

as an addition to some of the distilled waters and preparations of vinegar; in order to preserve them from decomposition; as a menstruum for extracting the virtues of some plants, preparatory to their being brought to the state of extracts and syrups; and in preparing many of the spirits. But it is in forming the tinctures that diluted alcohol is principally employed. Many of these are formed with the officinal alcohol (rectified spirit), but the majority, with diluted alcohol (proof spirit) as the menstruum. As the latter contains more than half its weight of water, it is well fitted for acting on those vegetables, the virtues of which are partly soluble in water and partly in alcohol. The apothecary, however, is, on no account, to substitute the commercial proof spirit for diluted alcohol, even though it should be of the same strength. On this point, the authors of the Dublin Pharmacopœia have very correctly remarked, that “almost all the spirit which is sold under the name of proof spirit, is contaminated with empyreumatic oil, and unfit for medical use.” But when it is recollected how variable the so called proof spirits are in strength, the objection to their use in pharmacy becomes still stronger. Thus, according to Mr. Brande, gin contains 51·6 per cent. of alcohol of 0·825; and the per centage of the same alcohol is 53·39 in brandy, 53·68 in rum, 53·90 in Irish whisky, and 54·32 in Scotch whisky. The alcohol on which these results are based already contains 11 per cent. of water.

B.

ALUMEN.

Preparations of Alum.

ALUMEN EXSICCATUM. *U.S., Lond., Ed.* ALUMEN SICCATUM. *Dub. Dried Alum.*

“Take of Alum *any quantity*. Melt it in an earthen or iron vessel over the fire, and continue the heat till it becomes dry; then rub it into powder.” *U. S.*

“Melt Alum in an earthen vessel over the fire; then increase the heat until ebullition has ceased.” *Lond.*

The *Edinburgh* and *Dublin* processes agree with that of the *U. S. Pharmacopœia*. When alum is heated, it quickly dissolves in its water of crystallization, which, if the heat be continued, is gradually driven off; and the salt swells up exceedingly, so as to make it expedient to use a vessel, the capacity of which is at least equal to three times the bulk of the alum operated on. When the boiling up has ceased, it is a sign that all the water has been driven off.

Properties. Dried alum is in the form of an opaque white powder, possessing a more astringent taste than the crystallized salt. Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, it loses from 41 to 46 per cent. of its weight in dissipated water. If, however, the heat be strongly urged, some of the acid is driven off, and the loss becomes still greater. Dried alum resists the action of water for a long time, showing that the process to which it has been subjected has altered its state of aggregation. In composition, it differs from crystallized alum merely in the absence of water.

Medical Properties and Uses. Dried alum has occasionally been given in obstinate constipation, with the effect of gently moving the bowels, and of affording great relief from pain. (See *Alumen*.) The dose is about half that of alum. Its principal medical use is as a mild escharotic for destroying fungous flesh.

B.

LIQUOR ALUMINIS COMPOSITUS. *Lond. Compound Solution of Alum.*

“Take of Alum, Sulphate of Zinc, each, *an ounce*; boiling Water *three pints* [Imperial measure]. Dissolve the Alum and Sulphate of Zinc together in the Water, and afterwards strain.” *Lond.*

This was formerly called *aqua aluminosa Bateana*, or *Bates’s alum water*. It is a powerful astringent solution, and is employed for cleansing and stimulating foul ulcers, and as an injection in gleet and leucorrhœa. It is also sometimes employed as a collyrium in ophthalmia after depletion; but when used in this way it must be diluted. A convenient formula is half a fluidounce of the solution mixed with six and a half fluidounces of rose water. B.

AMMONIA.

Preparations of Ammonia.

AMMONIÆ BICARBONAS. *Dub. Bicarbonate of Ammonia.*

“Take of Water of Carbonate of Ammonia *any quantity*. Expose it, in a suitable apparatus, to a stream of carbonic acid gas, evolved during the solution of white marble in Diluted Muriatic Acid, until the alkali is saturated. Then let it rest to form crystals, which are to be dried without heat, and kept in a closely stopped vessel.” *Dub.*

This salt is officinal only in the Dublin Pharmacopœia. The process by which it is formed consists in saturating the sesquicarbonate (officinal carbonate) with carbonic acid, whereby this salt becomes a bicarbonate. The sesquicarbonate consists of three eqs. of acid and two of ammonia; and, by gaining one eq. of carbonic acid, becomes a bicarbonate, consisting of four eqs. of acid and two of ammonia. These proportions reduced to their lowest terms give for the composition of this bisalt, two eqs. of carbonic acid and one of ammonia. The crystallized salt contains two eqs. of water.

Bicarbonate of ammonia, as prepared by this process, is in the form of crystals, which have a faint ammonical taste and smell, and are permanent in the air. It is less soluble in water than the sesquicarbonate, requiring eight times its weight of that liquid to dissolve it. It possesses, though in an inferior degree, the medical properties of the latter salt. As it furnishes the practitioner with the means of prescribing ammonia in a convenient and palatable form, Dr. Barker deems its introduction into the officinal list of the Dublin College a valuable improvement. It ought to have been shown, however, in what respect the Dublin preparation differs from the bicarbonate, obtained by exposing the sesquicarbonate to the air; for if they be identical, it cannot be necessary to resort to the Dublin formula for preparing this bisalt. The dose of bicarbonate of ammonia is from six to twenty-four grains, dissolved in cold water, as hot water decomposes it. B.

AMMONIÆ CARBONAS. *U.S., Ed., Dub. AMMONIÆ SESQUICARBONAS. Lond. Carbonate of Ammonia. Mild Volatile Alkali.*

“Take of Muriate of Ammonia *a pound*; Chalk, dried, *a pound and a half*. Pulverize them separately; then mix them thoroughly, and sublime with a gradually increasing heat.” *U.S.*

“Take of Muriate of Ammonia, pulverized and well dried, Dried Carbonate of soda, each, *one part*. Put the mixture into an earthenware retort, and with a heat gradually increased, sublime the Carbonate of Ammonia into a refrigerated receiver.” *Dub.*

The *London* and *Edinburgh* processes are the same as that of the U. S. Pharmacopœia.

In the above processes, by the reciprocal action of the salts employed, the carbonic acid unites with the ammonia, generating carbonate of ammonia, and the muriatic acid with the lime or soda, so as to form water and chloride of calcium, or the same liquid and chloride of sodium. The carbonate and water sublime together as a hydrated carbonate of ammonia, and the residue is chloride of calcium in the U. S., London, and Edinburgh processes, and chloride of sodium, or common salt, in the Dublin. In conducting the process, the retort should be of earthenware, and have a wide cylindrical neck; and the receiver should be cylindrical, to facilitate the extraction of the sublimate. The relative quantities of chalk and muriate of ammonia for mutual decomposition, are 50·62 of the former and 53·57 of the latter, or one eq. of each. The Pharmacopœias use a great excess of chalk. An excess is desirable to ensure the perfect decomposition of the muriate of ammonia, any redundancy of which would sublime along with the carbonate, and render it impure. The employment of carbonate of soda, in the Dublin process, affords a product of greater whiteness, but is objectionable on the score of expense. The proportions of the muriate and alkaline carbonate, directed by this College, correspond almost precisely with the equivalents; but in practice, the quantity of carbonate of soda is found insufficient.

Carbonate of ammonia is obtained on a large scale, generally by subliming the proper materials from an iron pot into a large earthen or leaden receiver. Sulphate of ammonia may be substituted for the muriate with much economy, as was shown by Payen. Large quantities of this carbonate are manufactured indirectly from *gas liquor* and *bone spirit*; the ammoniacal products in these liquors being successively converted into sulphate, muriate, and carbonate of ammonia. (See *Ammoniæ Murias*.) The salt as first obtained has a slight odour of tar, and leaves a blackish carbonaceous matter when dissolved in acids. Hence it requires to be refined, which is effected in iron pots, surmounted with leaden heads.

Properties. Carbonate (sesquicarbonate) of ammonia, recently prepared, is in white, moderately hard, translucent masses, of a fibrous and crystalline appearance, a pungent ammonical smell, and a sharp penetrating taste. It possesses an alkaline reaction, and when held under a piece of turmeric paper changes it to brown, owing to the escape of monocarbonate of ammonia. When long or carelessly kept, it gradually passes into the state of bicarbonate, becoming opaque and friable, and falls to powder. It is soluble without residue in about four times its weight of cold water, and is decomposed by boiling water with effervescence. According to Dr. Barker (*Observations on the Dublin Pharmacopœia*), it dissolves abundantly in diluted alcohol, as also in heated alcohol of the sp. gr. 0·836, with effervescence of carbonic acid. When heated on a piece of glass, it should evaporate without residue, and if turmeric paper held over it undergoes no change, it has passed into bicarbonate. When saturated with nitric acid, neither chloride of barium nor nitrate of silver causes a precipitate. The non-action of these tests shows the absence of sulphate and muriate of ammonia. It is decomposed by acids, the fixed alkalies and their carbonates, lime-water and magnesia, solution of chloride of calcium, alum, acid salts, such as bitartrate and bisulphate of potassa, solutions of iron (except the tartrate of iron and potassa), corrosive sublimate, the acetate and subacetate of lead, and the sulphates of iron and zinc.

Composition. It consists of three eqs. of carbonic acid 66·36, two of ammonia 34·3, and two of water 18=118·66; or which comes to the same

thing, of one eq. of bicarbonate 61·39, and one of monocarbonate 39·27, combined with the same quantity of water. The medicinal carbonate of ammonia is, therefore, when perfect, a hydrated *sesquicarbonate*, as it is called by the London College. Dalton and Scanlan, however, have rendered it probable that it is a double salt; for when treated with a small quantity of cold water, monocarbonate is dissolved and bicarbonate left. When converted into bicarbonate by exposure to the air, each eq. of the medicinal salt loses one eq. of monocarbonate, a change which leaves the acid and base in the proper proportion to form the bisalt. The mutual decomposition of the salts employed in its preparation, would generate, if no loss occurred, the monocarbonate, and not the sesquicarbonate. The way in which the latter salt is formed may be thus explained. By the mutual decomposition of three eqs. of muriate of ammonia and of chalk respectively, three eqs. of carbonate of ammonia, three of water, and three of chloride of calcium are generated. During the operation, however, one eq. of ammonia and one of water, forming together oxide of ammonium, are lost; so that there remain to be sublimed, three eqs. of carbonic acid, two of ammonia, and two of water; or, in other words, the exact constituents of the hydrated sesquicarbonate. When this is re-sublimed in the process of refining, two eqs. of the salt lose one eq. of carbonic acid, and become one eq. of 5·4 carbonate of ammonia.

Medical Properties and Uses. Carbonate of ammonia is stimulant, diaphoretic, antispasmodic, powerfully antacid, and in large doses emetic. Under certain circumstances it may prove expectorant; as when, in the last stages of phthisis, it facilitates, by increasing the muscular power, the excretion of the sputa. As a stimulant, it is exhibited principally in typhus fever, and very frequently in connexion with wine whey. Its principal advantage, in this disease, is its power to increase the action of the heart and arteries without unduly exciting the brain. It is employed, with a view to the same effect, and as an antacid, in certain stages of atonic gout, and in the derangements of the stomach supervening on habits of irregularity and debauchery. As a diaphoretic, it is resorted to in gout and chronic rheumatism, particularly the latter, in conjunction with guaiac. In diabetes it has been recommended by Dr. Barlow in England, and Bouchardat in France. In cases of scrofula attended with languid circulation and dry skin, it is said to produce excellent effects. It is very seldom used as an emetic; but is supposed to act with advantage, in this way, in some cases of paralysis. As an external application, it is rubefacient, and may be employed in several ways. Reduced to fine powder, and mixed with some mild ointment, it is useful in local rheumatism. One part of it, incorporated with three parts of extract of belladonna, forms a plaster very efficacious in relieving local and spasmodic pains. Coarsely bruised, and scented with oil of lavender, it constitutes the common smelling salts, so much used as a nasal stimulant in syncope and hysteria. The dose as a stimulant, is from five to ten grains, every two, three, or four hours, in the form of pill, or dissolved in some aqueous vehicle; and as an emetic, thirty grains, to be repeated if necessary, and assisted by free dilution. It should never be given in powder, on account of its volatile nature. Pills of it may be made up with some vegetable extract, as of chamomile for example, and should be dispensed in a wide-mouthed vial, and not in a box.

Carbonate of ammonia is used as a chemical agent in preparing Zinc Oxidum, *U. S.*, *Lond.*, *Ed.*, and Ferrum Tartarizatum, *Ed.* It is sometimes employed to make effervescent draughts, with lemon juice or tartaric acid.

Off. Prep. Cuprum Ammoniatum, *U. S.*, *Lond.*, *Ed.*, *Dub.*; Liquor

Ammonia Acetatis, *U. S., Lond., Ed., Dub.*; Liquor Ammonia Sesquicarbonatis, *Lond., Ed., Dub.*; Potassæ Bicarbonas, *Ed.*; Spiritus Ammonia. *Dub.* B.

LIQUOR AMMONIAE SESQUICARBONATIS. *Lond.* AMMONIAE CARBONATIS AQUA. *Ed., Dub.* *Solution of Sesquicarbonate of Ammonia. Solution of Carbonate of Ammonia.*

“Take of Sesquicarbonate of Ammonia *four ounces*; Distilled Water *a pint* [Imperial measure]. Dissolve the Sesquicarbonate of Ammonia in the Water, and strain.” *Lond.*

“Take of Carbonate of Ammonia *four parts*; Distilled Water *fifteen parts*. Dissolve the Carbonate of Ammonia in the Water, and filter through paper. The specific gravity of this solution is 1.090.” *Dub.*

The *Edinburgh* solution is of the same strength as the London.

This preparation may be viewed as a saturated aqueous solution of carbonate of ammonia. The wine pint of water, formerly ordered by the London College, was not, according to Mr. Phillips, sufficient to dissolve the salt. The pint now directed is the Imperial (20 fluidounces), and is adequate for that purpose. This preparation is very properly omitted in the United States Pharmacopœia; as it is liable to change by keeping. The dose is from half a fluidrachm to a fluidrachm, given in any bland liquid.

This solution is used by the London College in preparing the tartrate of potassa and iron.

Off. Prep. Ammonia Bicarbonas, *Dub.*; Linimentum Ammonia Sesquicarbonatis, *Lond.*; Pilulæ Cupri Ammoniaci, *Ed.* B.

AMMONIAE HYDROSULPHURETUM. *Dub.* *Hydrosulphuret of Ammonia. Solution of Hydrosulphate of Ammonia.*

“Take of Sulphuret of Iron, in coarse powder, *five parts*; Sulphuric Acid *seven parts*; Water *thirty-two parts*; Water of Caustic Ammonia *four parts*. Put the Sulphuret into a retort; then gradually pour on the Acid, previously diluted with the Water, and in a suitable apparatus, transmit the gas evolved through the Water of Ammonia. Towards the end of the process, apply a gentle heat to the retort.” *Dub.*

This preparation is a solution of hydrosulphate of ammonia in water, and is formed by passing a stream of hydrosulphuric acid gas (sulphuretted hydrogen) through a portion of water of ammonia, usually contained in a Wolfe's bottle. The hydrosulphuric acid is generated by the action of dilute sulphuric acid on sulphuret of iron. The water yields its oxygen to the iron forming protoxide of iron, with which the sulphuric acid combines; while the hydrogen of the water, uniting with the sulphur, generates the hydrosulphuric acid.

Properties. Solution of hydrosulphate of ammonia is a liquid of a greenish-yellow colour, very fetid smell, and acid, disagreeable taste. It is characterized by giving coloured precipitates with neutral metallic solutions, for which it is much used as a test. It is decomposed by acids, which cause the escape of hydrosulphuric acid with effervescence, and the deposition of sulphur. The salt present in it appears to be a bihydrosulphate, consisting of two eqs. of hydrosulphuric acid 34.2, and one of ammonia 17.15 = 51.35.

Medical Properties and Uses. This preparation acts on the system as a sedative, lessening the action of the heart and arteries in a remarkable degree, and producing nausea, vomiting, vertigo, and drowsiness. It has been used in diabetes mellitus, in which disease it was proposed as a remedy by Dr. Cruickshank, for the purpose of lessening the morbid appetite which often attends that affection, and has been employed by Dr. Rollo and others.

The dose is from five to six drops in a tumblerful of water three or four times a day, to be gradually increased until giddiness is produced. This solution has been expunged from the U. S. and Edinburgh Pharmacopœias. B.

LIQUOR AMMONIÆ. U. S., *Lond.* AMMONIÆ AQUA. *Ed.*
AMMONIÆ CAUSTICÆ AQUA. *Dub.* AQUA AMMONIÆ. *Solution of Ammonia. Water of Ammonia*

“Take of Muriate of Ammonia, in fine powder, Lime, each, *a pound*; Distilled Water *a pint*; Water *nine fluidounces*. Break the Lime in pieces, and pour the Water upon it in an earthen or iron vessel; then cover the vessel, and set it aside till the Lime falls into powder and becomes cold. Mix this thoroughly with the Muriate of Ammonia in a mortar, and immediately introduce the mixture into a glass retort. Place the retort upon a sand-bath, and adapt to it a receiver, previously connected, by means of a glass tube, with a quart bottle containing the Distilled Water. Then apply heat, to be gradually increased till the bottom of the iron vessel containing the sand becomes red-hot; and continue the process so long as ammonia comes over. Remove the liquor contained in the quart bottle, and for every fluidounce of it add three and a half fluidrachms of Distilled Water, or so much as may be necessary to raise its specific gravity to 0.96. Keep the solution in small bottles well stopped.

“Solution of Ammonia may also be prepared by mixing one part, by measure, of Stronger Solution of Ammonia with two parts of Distilled Water.” *U. S.*

“Take of Hydrochlorate [Muriate] of Ammonia *ten ounces*; Lime *eight ounces*; Water *two pints* [Imperial measure]. Put the Lime slaked with Water into a retort; then add the Hydrochlorate of Ammonia broken into small pieces, and the remainder of the Water. Distil fifteen fluidounces [Imp. meas.] of Solution of Ammonia.” *Lond.* The specific gravity of this Solution is 0.960.

“Take of Muriate of Ammonia, in powder, *three parts*; Lime, recently burnt, *two parts*; Water *ten parts*. Pour one part of the Water, previously heated, on the Lime, placed in an earthen vessel, and cover it. Dissolve the salt in the remainder of the Water, also heated. When the lime has fallen into powder and become cool, put it into a retort, and add to it the saline solution also cold. Then distil five parts with a medium heat into a refrigerated receiver. The specific gravity of this Solution is 0.950.” *Dub.*

The *Edinburgh* process includes the formation of Liquor Ammonia Fortior and this preparation at one operation. The process has been quoted at length and explained at page 82. (See *Liquor Ammonia Fortior*.) The Liquor Ammonia of this College is directed to have the sp. gr. 0.960.

The object of the above processes is to obtain a weak aqueous solution of the alkaline gas ammonia. The muriate of ammonia is decomposed by the superior affinity of the lime for its acid, ammonia is disengaged, and the lime, combining with the acid, forms chloride of calcium and water. The ammonia is either evolved from the dry materials and passed into water, by which it is absorbed, as in the U. S. and Edinburgh processes, or distilled over in connexion with water, as directed by the London and Dublin Colleges. The lime is slaked to render it pulverulent, in which state it acts more readily on the muriate of ammonia. The receiver directed in the *United States* process is intended to retain any water holding in solution undecomposed muriate, or the oily matter sometimes contained in this salt, as well as other impurities, which may be driven over by the heat; while the pure gas passes forward through the glass tube into the bottle containing the

distilled water, which should not more than half fill it, on account of the increase of bulk which it acquires during the absorption of the gas. The tube should continue down to near the bottom of the bottle, and pass through a cork, loosely fitting its mouth. To prevent the regurgitation of the water from the bottle into the receiver, the latter should be furnished with a Welter's tube of safety. Large bottles are improper for keeping the water of ammonia obtained; as, when they are partially empty, the atmospheric air contained within them is apt to furnish a little carbonic acid to the ammonia.

In the process of the London Pharmacopœia, which was very much changed in the revision of 1836, a given measure of water of ammonia is distilled over from the materials employed. The muriate of ammonia, instead of being pulverized, is directed to be broken into small pieces, in order to avoid the loss of gas which the powdered form of the salt is apt to occasion from the too sudden extrication of the ammonia. The present is a decided improvement on the last London process. Time is saved in conducting it, the boiling of part of the water is omitted, straining the mixed solution is dispensed with, and a larger proportional amount of water of ammonia is obtained from the materials. By the old process Mr. Phillips states that "at least fifty measures of a mixed solution of ammonia and chloride of calcium were subjected to distillation in order to procure twelve measures of product. In the present Pharmacopœia the same quantity is obtained by heating only thirty-two measures of the mixed solution."

The general plan of the *Dublin* process is the same as that of the *London*. The differences consist in heating the portions of water intended to slake the lime and dissolve the muriate, and in adding the saline solution instead of the solid salt to the lime. Dr. Barker objects to the *Dublin* formula that the ammonia is apt to be generated in the retort faster than the water present can take it up, which circumstance causes a loss. He, therefore, believes it would be an improvement to direct that part of the water should be placed in the receiver. Another objection to the formula is the use of heated water; for cold water will readily slake lime, and dissolve powdered muriate of ammonia.

The proportion of lime varies in the different formulæ. The equivalent proportions are 53·57 of salt and 28·5 of lime, a quantity of the latter only a little more than half the weight of the former. By comparing these numbers with those expressing the proportions of the ingredients employed, it will be seen that all the Pharmacopœias use an excess of lime, the excess being least in the *Dublin*. The earth is most in excess in the *U. S.* and *Edinburgh* processes, where equal parts are used, and Mr. Phillips alleges that its bulk is an inconvenience by requiring large vessels; but Dr. Hope contends that the excess of lime is useful by accelerating the disengagement of the ammonia, and by rendering a less elevated temperature necessary. The excess of lime, to the extent directed by the *Dublin* College, is stated by Dr. Barker to be necessary to compensate for the impurities in ordinary lime. The use of no more lime than is absolutely required to produce complete decomposition, has the incidental advantage of rendering the residual solution of chloride of calcium less impure; an object of some importance where it is reserved for purification, as is done by the *Dublin* College.

The three Pharmacopœias which include *Liquor Ammonix Fortior* (*U. S.*, *London*, and *Edinburgh*) give directions for its dilution so as to bring it to the strength of *Liquor Ammonix*. This is effected by mixing one measure of the stronger preparation with two measures of distilled water, (*U. S.*, *Lond.*) or with two and a half measures (*Ed.*). By dilution to this extent the stronger solution is brought uniformly to the sp. gr. of 0·960; the

Edinburgh solution requiring more water, because more concentrated. (See page 83.)

Properties. The properties of "Stronger Solution of Ammonia" have already been indicated. (See *Liquor Ammonia Fortior*.) Those of the officinal solution of ammonia, described in this place, are the same in kind, but weaker in degree. Its sp. gr. in the U. S., London, and Edinburgh Pharmacopœias is the same, 0.960; in the Dublin, 0.950. When of the density 0.960, 100 grains of it saturate 30 grains of officinal sulphuric acid. It is incompatible with acids, and with acidulous and most earthy and metallic salts; but it does not decompose the salts of lime, baryta, or strontia, and those of magnesia only partially. If precipitated by lime-water, the ammonia is partly carbonated. When saturated with nitric acid it should give no precipitate with carbonate of ammonia or nitrate of silver. A precipitate with the former shows earthy matter; with the latter, muriatic acid or a chloride.

Composition. Water is capable of absorbing 670 times its volume of ammoniacal gas at 50°, and increases its bulk about two-thirds. But the officinal solution of ammonia is by no means a saturated one. Thus the ammonia contained in the U. S., London, and Edinburgh preparation is about 10 per cent.; in the Dublin, about 12½ per cent. For the percentage of ammonia in the *Liquor Ammonia Fortior*, see that title. The following table, constructed by Sir H. Davy, gives the percentage of ammoniacal gas in aqueous solutions of different specific gravities.

Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.
0.8750	32.50	0.9326	17.52	0.9545	11.56
0.8875	29.25	0.9385	15.88	0.9573	10.82
0.9000	26.00	0.9435	14.53	0.9577	10.17
0.9054	25.37	0.9476	13.46	0.9619	9.60
0.9166	22.07	0.9513	12.40	0.9692	9.50
0.9255	19.54				

Medical Properties and Uses. Solution of ammonia, usually called *water of ammonia*, is stimulant, sudorific, antacid, and rubefacient. It stimulates more particularly the heart and arteries, without unduly exciting the brain. It is rarely used internally, other ammoniacal preparations being preferred, the dose of which is larger and more easily managed. As a stimulant, it is occasionally employed in paralysis, hysteria, syncope, asphyxia, and similar affections, with a view to rouse the vital powers. In the same complaints it is often applied to the nostrils with advantage. As an antacid, it is one of the best remedies in heartburn, and for the relief of sick headache when dependent on acidity of stomach. In these cases it acts usefully also by stimulating the stomach. Externally applied, it may be made to act either as a rubefacient or vesicant. As a rubefacient it is employed united with oil in the form of volatile liniment. (See *Linimentum Ammonia*.) As a vesicant it is applied by means of a piece of linen wet with it. As such it has the advantages over cantharides of acting more speedily, and of not affecting the urinary organs. (See *Liquor Ammonia Fortior*, and *Linimentum Ammonia Compositum*.) The dose is from ten to thirty drops, largely diluted with water to prevent its caustic effect on the mouth and throat. When swallowed in an over-dose, its effects are those of a corrosive poison. The best antidotes are vinegar and lemon-juice, which act by neutralizing the

ammonia, and must be promptly applied to be useful. The consecutive inflammation must be treated on general principles.

LIQUOR AMMONIÆ ACETATIS. *U. S.*, *Lond.* AMMONIÆ ACETATIS AQUA. *Ed.*, *Dub.* SPIRITUS MINDERERI. *Solution of Acetate of Ammonia. Spirit of Mindererus.*

"Take of Diluted Acetic Acid *two pints*; Carbonate of Ammonia, in powder, *a sufficient quantity*. Add the Carbonate of Ammonia gradually to the Acid until it is saturated." *U. S.*

"Take of Sesquicarbonate of Ammonia *four ounces and a half*, or as much as may be sufficient; Distilled Vinegar *four pints* [Imperial measure]. Add the Sesquicarbonate of Ammonia to the Vinegar to saturation." *Lond.*

"Take of Distilled Vinegar (from French Vinegar in preference) *twenty-four fluidounces* [Imperial measure]; Carbonate of Ammonia *an ounce*. Mix them and dissolve the salt. If the solution has any bitterness, add by degrees a little Distilled Vinegar till that taste be removed. The density of the Distilled Vinegar should be 1.005, and that of the Aqua Acetatis Ammoniæ 1.011." *Ed.*

"Take of Carbonate of Ammonia *one part*. Add gradually, and with frequent agitation, as much warm Distilled Vinegar as may be necessary to saturate the ammonia, namely, about *thirty parts*. The saturation may be ascertained by means of litmus." *Dub.*

This preparation is an aqueous solution of acetate of ammonia. The process by which it is formed constitutes a case of single elective affinity. The acetic acid decomposes the carbonate, combines with the ammonia, forming the acetate of ammonia, and disengages the carbonic acid with effervescence. The British Colleges employ distilled vinegar, while, according to the United States Pharmacopœia, the saturation is effected with a pure acetic acid, diluted to a determinate extent with distilled water. (See *Acidum Aceticum Dilutum*.) The use of the acid in the latter form is a decided improvement; for besides furnishing the solution of the acetate of uniform strength, a result which cannot be attained by the employment of distilled vinegar, unless it be carefully brought to a given density, it avoids the production of a brownish solution, which uniformly follows the use of the latter, especially when it has been condensed in a metallic worm. The quantity of carbonate of ammonia necessary to saturate a given weight of the acid of average strength, cannot be laid down with precision, on account of the variable quality of this salt. The preparation, when made with the diluted acetic acid of the U. S. Pharmacopœia, contains 6 per cent. of acetate of ammonia. The addition of the salt to the acid, as directed in the U. S. and London Pharmacopœias, is more convenient than the contrary order; as the point of saturation is thus more easily attained. This point is best ascertained by the alternate use of turmeric and litmus paper; and it is a good rule to allow rather a slight acidity to prevail, which will be due to carbonic acid dissolved in the liquid, and will disappear as soon as this acid is dissipated by time.

Properties. Solution of acetate of ammonia, when made of pure materials, is a limpid and colourless liquid. Its taste is saline and resembles that of a mixture of nitre and sugar. If it contain an excess of alkali, its taste is bitterish. It should not be made in large quantities at a time, as its acid becomes decomposed, and a portion of carbonate of ammonia is generated. As formerly prepared, under the name of *spiritus Mindereri*, it was made from the impure carbonate of ammonia, containing animal oil, which modified the preparation by giving rise to a portion of ammoniacal soap. When pure it is not coloured by hydrosulphuric acid, nor precipitated by nitrate of silver or chloride of barium. When evaporated to dryness, the residue is wholly dissipated by heat, with the smell of ammonia. It is incompatible with acids, the fixed alkalies and their carbonates, lime-water, magnesia, sulphate of magnesia, corrosive sublimate, the sulphates of iron, copper, and zinc, and nitrate of silver. When it contains free carbonic acid, it produces with the acetate or subacetate of lead, a precipitate of carbonate of lead, which being mistaken for the sulphate, has sometimes led to the erroneous conclusion that sulphuric acid was present in the distilled vinegar, when this has been employed. Acetate of ammonia, the salt in solution in this preparation, is difficultly crystallizable, and very deliquescent. It may be obtained by sublimation from a mixture of equal parts of dry acetate of potassa or of lime, and muriate of ammonia. It consists of one eq. of acetic acid 51.48, and one of ammonia 17.15 = 68.63. When crystallized it contains seven eqs. of water 63.

Medical Properties and Uses. Solution of acetate of ammonia is a valuable diaphoretic, much employed in febrile and inflammatory diseases. According to the indications to be answered by its use, it is variously combined with nitre and antimonials, camphor and opium. If, instead of promoting its determination to the skin by external warmth, the patient walk about in a cool air, its action will be directed to the kidneys. It is sometimes used externally as a discutient. Mr. Brande speaks of it as an excellent application in mumps, applied hot upon a piece of flannel. Mixed in the quantity of a fluidounce with seven fluidounces of rose-water, and two fluidrachms of laudanum, it forms a useful collyrium in chronic ophthalmia. Dr. A. T. Thomson has used it as a lotion with good effect in porrigo affecting the scalp. The dose is from half a fluidounce to a fluidounce and a half, every three or four hours, mixed with water and sweetened with sugar. It proves sometimes very grateful to febrile patients, when prescribed with an equal measure of carbonic acid water. B.

SPIRITUS AMMONIÆ. U.S., Lond., Ed., Dub. *Spirit of Ammonia.*

“Take of Muriate of Ammonia, in fine powder, Lime, each, *a pound*; Alcohol *twenty fluidounces*; Water *nine fluidounces*. Slake the lime with the Water, mix it with the Muriate of Ammonia, and proceed in the manner directed for Solution of Ammonia, the Alcohol being introduced into the quart bottle instead of Distilled Water. When all the ammonia has come over, remove the liquor contained in the quart bottle, and keep it in small bottles well stopped.” U.S.

“Take of Rectified Spirit *two pints* [Imperial measure]; fresh-burnt Lime *twelve ounces* [a pound]; Muriate of Ammonia, in very fine powder, *eight ounces*; Water *six fluidounces and a half* [Imp. meas.]. Let the Lime be slaked with the Water in an iron or earthenware vessel, and cover the vessel till the powder be cold, mix the Lime and Muriate of Ammonia quickly and thoroughly in a mortar, and transfer the mixture at once into a

glass retort; adapt to the retort a tube which passes nearly to the bottom of a bottle containing the Rectified Spirit; heat the retort in a sand-bath gradually, so long as any thing passes over, preserving the bottle cool. The bottle should be large enough to contain one-half more than the spirit used." *Ed.*

"Take of Hydrochlorate [Muriate] of Ammonia *ten ounces*; Carbonate of Potassa *sixteen ounces*; Rectified Spirit, Water, each, *three pints* [Imperial measure]. Mix them, and distil three pints [Imp. meas.]." *Lond.*

"Take of Rectified Spirit *three pints*; Carbonate of Ammonia, coarsely powdered, *three ounces and a half*. Mix them, and dissolve the salt with a medium heat; then filter the solution." *Dub.*

The spirit of ammonia of the U. S. and Edinburgh Pharmacopœias is a solution of ammonia in rectified spirit: that of the London and Dublin Colleges, a solution of monocarbonate of ammonia in the same menstruum. The proportions of the ingredients of the *United States* formula are so adjusted as to give a preparation, containing between 10 and 11 per cent. of ammonia, and capable of saturating about 30 per cent. of officinal sulphuric acid. Accordingly, it agrees, as it was intended it should, in ammoniacal strength with the U. S. *Liquor Ammonix*. Its sp. gr. is 0.831, or thereabouts. The *Edinburgh* spirit may be roughly estimated to be less than one-third as strong as that of the U. S. Pharmacopœia; for the ammonia extricated from the same quantity of muriate of ammonia, is passed into three times as much rectified spirit. The density of the *Edinburgh* spirit of ammonia is "about 0.845." As rectified spirit becomes lighter by the absorption of ammoniacal gas, it is evident that the alcoholic menstruum gains water as well as ammonia in the distillation. This addition of water to the product is prevented by the intermediate receiver, used in the U. S. process, and consequently the spirit of ammonia obtained has a less specific gravity than that of rectified spirit. In the *London* process a double decomposition takes place between the muriate of ammonia and carbonate of potassa, resulting in the formation of the monocarbonate of ammonia which distils over with the spirit, and chloride of potassium which remains behind in solution. This process is somewhat wasteful, as part of the carbonate formed remains undissolved in the receiver, in an imperfectly crystalline state, the spirit not being capable of dissolving the whole which comes over. The *Dublin* process consists in merely dissolving the officinal carbonate in heated rectified spirit. The officinal carbonate is a sesquicarbonate; and during its solution in the spirit, just so much carbonic acid is disengaged with effervescence, as to convert it into monocarbonate, of which thirty grains dissolve in each fluidounce. The spirit thus obtained, therefore, contains the ammonia, carbonated to the same extent in which it exists in the *London* preparation.

Properties. The U. S. spirit of ammonia, formerly called *ammoniated alcohol*, is a transparent colourless liquid, having a strong ammoniacal odour, and acrid taste. When good it does not effervesce with diluted muriatic acid; but if old or carelessly kept, it is apt to be partially carbonated, as shown by this test. It, however, absorbs carbonic acid more slowly than *Liquor Ammonix*. The *Edinburgh* preparation has similar properties with those above given. The *London* and *Dublin* spirits have a weaker odour of ammonia. The former has the officinal density 0.860. Both effervesce with acids. Though carbonated, they are more pungent and alkaline than if they contained the sesquicarbonate; as the ammonia present in them is combined with one-third less of carbonic acid.

Medical Properties and Uses. Spirit of ammonia is stimulant and anti-

spasmodic, and is given in hysteria, flatulent colic, and nervous debility. It is, however, not much used; the aromatic spirit, which is pleasanter and has similar properties, being preferred. The dose of the U. S. preparation is from ten to thirty drops in a wineglassful of water; of the Edinburgh, somewhat larger. The dose of the carbonated spirit is still larger—from thirty drops to a teaspoonful, properly diluted. All these spirits dissolve resins, gum-resins, camphor, and the volatile oils; but the caustic are more active solvents than the carbonated preparations. The Edinburgh College use their spirit for making the aromatic and fetid spirits of ammonia, and the *ammoniated tinctures*, as is seen by the list subjoined.

Off. Prep. Spiritus Ammoniaë Aromaticus, *Ed.*; Spiritus Ammoniaë Fœtidus, *Ed.*; Tinctura Castorei Ammoniata, *Ed.*; Tinct. Guaiaci Ammoniata, *Ed.*; Tinct. Opii Ammoniata, *Ed.*; Tinct. Valerianæ Ammoniata, *Ed.*, *Dub.* B.

SPIRITUS AMMONIÆ AROMATICUS, U. S., *Lond.*, *Ed.*, *Dub.* *Aromatic Spirit of Ammonia.*

“Take of Muriate of Ammonia *five ounces*; Carbonate of Potassa *eight ounces*; Cinnamon, bruised, Cloves, bruised, each, *two drachms*; Lemon Peel *four ounces*; Alcohol, Water, each, *five pints*. Mix them and distil seven pints and a half.” *U. S.*

The London formula is the original of the above, and, therefore, need not be given.

“Take of Spirit of Ammonia *eight fluidounces*; Volatile Oil of Lemon Peel *a fluidrachm*; Volatile Oil of Rosemary *a fluidrachm and a half*. Dissolve the Oils in the Spirit by agitation.” *Ed.*

“Take of Spirit of Ammonia *two pints*; Essential Oil of Lemons *two drachms*; Nutmegs, bruised, *half an ounce*; Cinnamon Bark, bruised, *three drachms*. Macerate in a covered vessel for three days, shaking occasionally; then distil a pint and a half.” *Dub.*

The *London* and *U. S.* aromatic spirit of ammonia is made on the same plan as the London carbonated simple spirit; namely, by impregnating the menstruum with monocarbonate of ammonia, formed by double decomposition between muriate of ammonia and carbonate of potassa. Thus the product is a spirituous solution of the monocarbonate, impregnated with aromatics. From the relation between the muriate of ammonia and the quantity of liquid distilled, it will be found that this aromatic spirit is only one-fourth as ammoniated as the corresponding simple spirit. This aromatic spirit is also weaker in the density of the alcohol present in it; for, while in the corresponding simple spirit the distilled product is just equal to the rectified spirit employed, in the aromatic spirit it is half as much again; the proportional excess being water. Hence it is that the aromatic spirit of this process is so much heavier than the corresponding simple spirit; the former having the specific gravity 0.914, the latter 0.860, as determined by the London College. The aromatic spirit of the *Edinburgh* College is a mere solution of certain volatile oils in the caustic, simple spirit of that College. The omission to distil is a defect in this process; for if the volatile oils contain impurity, the preparation will be coloured and turbid. The *Dublin* College make the preparation by distilling their carbonated simple spirit with the aromatics.

Medical Properties and Uses. Aromatic spirit of ammonia is fitted to fulfil the same indications as the simple spirit; but is much more used, on account of its grateful taste and smell. It is advantageously employed as a stimulant antacid in sick headache. The dose is from twenty to sixty drops or more, sufficiently diluted with water. This spirit is compatible with sul-

phate of magnesia, and may be usefully added to aperient draughts of that salt, to render them less offensive to the stomach.

Off. Prep. Tinctura Colchici Composita, *Lond.*; Tinct. Guaiaci Ammoniata, *U. S., Dub., Lond.*; Tinct. Valerianæ Ammoniata, *U. S., Lond.* B.

SPIRITUS AMMONIÆ FÆTIDUS. *Lond., Ed., Dub. Fetid Spirit of Ammonia.*

“Take of Hydrochlorate [Muriate] of Ammonia *ten ounces*; Carbonate of Potassa *sixteen ounces*; Rectified Spirit, Water, each, *three pints* [Imperial measure]; Assafetida *five ounces*. Mix them; then with a slow fire distil *three pints*.” *Lond.*

“Take of Spirit of Ammonia *ten fluidounces and a half* [Imp. meas.]; Assafetida *half an ounce*. Break the Assafetida into small fragments, digest it in the Spirit for twelve hours, and distil over ten fluidounces and a half by means of a vapour-bath heat.” *Ed.*

“Take of Spirit of Ammonia *two pints*; Assafetida *an ounce and a quarter*. Macerate in a close vessel for three days, shaking occasionally; then pour off the clear liquor, and distil a pint and a half.” *Dub.*

This preparation differs from spirit of ammonia only in containing a small proportion of the volatile oil of assafetida, which has little other effect than to communicate an unpleasant odour and taste to the spirit. It is colourless at first, but becomes brownish with age. It is given in hysteria in doses of from thirty drops to a fluidrachm.

ANTIMONIUM.

Preparations of Antimony.

ANTIMONII OXIDUM. *Ed. Oxide of Antimony. Sesquioxide of Antimony.*

“Take of Sulphuret of Antimony, in fine powder, *four ounces*; Muriatic Acid (commercial) *a pint* [Imperial measure]; Water *five pints* [Imp. meas.]. Dissolve the Sulphuret in the Acid with the aid of a gentle heat; boil for half an hour; filter; pour the fluid into the Water; collect the precipitate on a calico filter; wash it well with cold water, then with a weak solution of Carbonate of Soda, and again with cold water till the water ceases to affect reddened litmus paper. Dry the powder over the vapour bath.” *Ed.*

This is a new official of the Edinburgh College. It is formed precisely on the same principles as the powder of Algaroth, described in the next article. As the object of the process is to obtain a pure oxide, the precipitate is washed with a weak solution of carbonate of soda to remove sesquichloride, and afterwards with water to separate any remains of alkali. The soda removes the sesquichloride, by forming with it sesquioxide of antimony and chloride of sodium. Sesquioxide of antimony is a snow-white heavy powder, permanent in the air, insoluble in water, but readily soluble in muriatic or tartaric acid, or in a boiling solution of bitartrate of potassa. When heated in close vessels, it becomes yellow, fuses at a full red heat, and finally sublimes in crystalline needles. When cooled from a state of fusion, it forms a fibrous crystalline mass. Heated in open vessels, it suddenly becomes red-hot, and, by the absorption of oxygen, changes into antimonious acid, which differs from the oxide in being insoluble in muriatic acid, less fusible, and not volatile. This oxide is the active ingredient of all the medicinal preparations of antimony. It is frequently impure from containing antimonious acid, in which case it will not be *entirely* soluble in muriatic acid. When antimonious acid is substituted for it, the fraud may be detected by the spurious preparation being *entirely* insoluble

in muriatic acid. It consists of two eqs. of antimony and three of oxygen ($2\text{Sb} + 3\text{O}$).

Medical Properties. This oxide possesses the general therapeutic properties of the antimonials. It deserves more attention than has been paid to it, and its effects, comparatively with tartar emetic, should be carefully studied. It is probable that its sedative operation would be found the same, with less nausea and disturbance of the stomach. Unfortunately, like antimonial powder, it is very unequal in its effects. The dose is from three to ten grains, repeated every two or three hours, and given in powder with syrup or molasses, or in pill made up with confection of roses. B.

ANTIMONII OXYDUM NITROMURIATICUM. *Dub. Nitromuriatic Oxide of Antimony. Powder of Algaroth.*

“Take of Prepared Sulphuret of Antimony *twenty parts*; Muriatic Acid *one hundred parts*; Nitric Acid *one part*. Add the Sulphuret gradually to the Acids, previously mixed in a glass vessel, avoiding the vapours. Digest with a heat gradually increased, until the effervescence cease, and then boil for an hour. Receive the cooled and filtered liquor in a gallon of water. Wash the Oxide of Antimony, after it has subsided, repeatedly, in a sufficiently large quantity of water, until the liquor poured off be perfectly free from acid, as known by the test of litmus. Lastly, dry the oxide on bibulous paper.” *Dub.*

The object of this process is to obtain the *oxychloride of antimony*, consisting of the sesquioxide and sesquichloride, and formerly called *powder of Algaroth*. When sesquisulphuret of antimony is dissolved, by the aid of heat, in muriatic acid, a double decomposition takes place, resulting in the formation of sesquichloride of antimony (butter of antimony) and hydrosulphuric acid (sulphuretted hydrogen), which by its evolution causes the effervescence. When the sesquichloride is poured into a large quantity of water, the greater part of it is converted into muriatic acid and sesquioxide, the former remaining in solution with a little of the undecomposed sesquichloride, the latter falling in union with the remainder of it, as a white flocculent precipitate, constituting the oxychloride of antimony, or powder of Algaroth. The precipitate is washed for the purpose of freeing it from adhering muriatic acid. The heat should be applied moderately at first, for fear the materials should unduly swell; but towards the close of the process it should be increased, to ensure the complete action of the acid. The small portion of nitric acid used by the College is not necessary to assist the muriatic acid in dissolving the sesquisulphuret; but it acts usefully by decomposing any remains of hydrosulphuric acid which may exist in the solution, and which, by its presence, would impair the whiteness of the oxychloride, when precipitated in the next step of the process by the water. The employment of nitric acid, for the purpose of giving whiteness to the product, originated with the late Dr. Perceval of Dublin. There exists a defect in the formula; inasmuch as the ingredients are taken in parts, which are *relative* quantities, while the water is directed in the *absolute* quantity of a gallon.

Properties. Oxychloride of antimony is a white powder, having a crystalline appearance if left long in contact with the solution from which it is precipitated. When exposed to a red heat, it enters into fusion, and forms a yellow liquid, which, on cooling, concretes into a grayish crystalline mass of a pearly aspect. It consists mainly of sesquioxide, being composed of nine eqs. of sesquioxide 1378.8 and two of sesquichloride 470.92 = 1849.72. (*Malaguti and Johnston.*)

Medical Properties and Uses. The powder of Algaroth was formerly used in medicine, but, owing to its unequal operation, has been laid aside. It is employed in pharmacy in the preparation of tartar emetic, for which purpose it is placed among the preparations of the Dublin Pharmacopœia. It is also applied to the same use in the United States and Edinburgh Pharmacopœias, but without being recognised under a distinct name, being formed as the first step of the process adopted for preparing tartar emetic in those works. The name given to this oxide by the Dublin College is very exceptionable. It is not formed on correct chemical principles; neither has it any pharmaceutical convenience to recommend it.

B.

ANTIMONII ET POTASSÆ TARTRAS. *U.S.* ANTIMONII ET POTASSÆ TARTRAS sive TARTARUM EMETICUM. *Dub.* ANTIMONII POTASSIO-TARTRAS. *Lond.* ANTIMONIUM TARTARIZATUM. *Ed.* Tartrate of Antimony and Potassa. Tartarized Antimony. Tartar Emetic.

“Take of Sulphuret of Antimony, in fine powder, *four ounces*; Muriatic Acid *twenty-five ounces*; Nitric Acid *two drachms*; Water *a gallon*. Having mixed the Acids together in a glass vessel, add by degrees the Sulphuret of Antimony, and digest the mixture, with a gradually increasing heat, till effervescence ceases; then boil for an hour. Filter the liquor when it has become cold, and pour it into the Water. Wash the precipitated powder frequently with water, till it is entirely freed from acid, and then dry it. Take of this powder *two ounces*; Bitartrate of Potassa, in very fine powder, *two ounces and a half*; Distilled Water *eighteen fluidounces*. Boil the Water in a glass vessel; then add the powders previously mixed together, and boil for an hour; lastly, filter the liquor while hot, and set it aside to crystallize. By further evaporation, the liquor may be made to yield an additional quantity of crystals, which should be purified by a second crystallization.” *U.S.*

“Take of Sulphuret of Antimony, in fine powder, *four ounces*; Muriatic Acid (commercial) *a pint* [Imperial measure]; Water *five pints* [Imp. meas.]. Dissolve the Sulphuret in the Acid with the aid of a gentle heat; boil for half an hour; filter; pour the liquid into the Water; collect the precipitate on a calico filter, wash it with cold water till the water ceases to redden litmus paper, dry the precipitate over the vapour-bath. Take of this precipitate *three ounces*; Bitartrate of Potash, *four ounces and two drachms*; Water *twenty-seven fluidounces* [Imp. meas.]. Mix the powders, add the Water, boil for an hour, filter, and set the liquid aside to crystallize. The mother-liquor, when concentrated, yields more crystals, but not so free of colour, and, therefore, requiring a second crystallization.” *Ed.*

“Take of Nitromuriatic Oxide of Antimony *four parts*; Bitartrate of Potassa, in very fine powder, *five parts*; Distilled Water *thirty-four parts*. Boil the Water in a glass vessel; then gradually throw into it the Oxide and Bitartrate of Potassa, previously mixed, and boil for half an hour; then filter the liquor through paper, and crystallize by slow cooling.” *Dub.*

“Take of Sesquisulphuret of Antimony, rubbed to powder, Nitrate of Potassa, powdered, each, *two pounds*; Bitartrate of Potassa, powdered, *fourteen ounces*; Hydrochloric [Muriatic] Acid *four fluidounces* [Imperial measure]; Distilled Water *a gallon* [Imp. meas.]. Mix the Sesquisulphuret of Antimony, accurately, with the Nitrate of Potassa; the Hydrochloric Acid being then added, and the powder spread upon an iron plate, ignite it. Rub

what remains, when it is cold, to very fine powder, and wash it frequently with boiling water until it is free from taste. Mix the powder thus prepared with the Bitartrate of Potassa, and boil for half an hour in a gallon of Distilled Water. Strain the liquor while yet hot, and set it aside that crystals may form. These being removed and dried, let the liquor again evaporate that it may yield crystals." *Lond.*

This preparation is a double salt, consisting of tartrate of potassa, united with tartrate of the sesquioxide of antimony. The principle of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate (cream of tartar) with sesquioxide of antimony. The officinal processes all consist in boiling a mixture of cream of tartar and some form of sesquioxide with water. The U. S., Edinburgh, and Dublin Pharmacopœias now all agree in using the form of sesquioxide called *oxychloride of antimony*, or *powder of Algaroth*, which is officinal under a distinct name only in the Dublin Pharmacopœia, where it is called nitromuriatic oxide of antimony. (See *Antimonii Oxydum Nitromuriaticum*, under which title it is described.) In the U. S. and Edinburgh Pharmacopœias, the same substance is formed as the first step of the tartar emetic process. The London College employs for making tartar emetic, the *crocus of antimony*. This substance was used for the same purpose in the former Edinburgh Pharmacopœia; but upon the last revision of that work, the oxychloride was judiciously substituted for it.

The Pharmacopœias which use the oxychloride, agree in the same general plan of making it. The sesquisulphuret of antimony is dissolved in from five to six times its weight of muriatic acid; assisted by a hundredth of nitric acid in the U. S. and Dublin formulas, but without this acid in the Edinburgh. The solution is thrown into a large quantity of water, equal to about 25 or 30 times the weight of the sulphuret employed, and the oxychloride is precipitated. This is mixed with from one and a quarter to about one and a half times its weight of cream of tartar, and boiled from half an hour to an hour, with about eight times its weight of distilled water; and the liquor obtained is filtered while hot and set aside to crystallize. By further evaporation the mother-liquor may be made to yield a second crop of crystals, which, not being free from colour, must be purified by a second crystallization. When no more crystals can be obtained, the liquor which is left contains, according to Knapp, a gummy salt which consists of tartrate of potassa, united to the tertartrate of sesquioxide of antimony. If this liquor be boiled with a fresh portion of oxychloride, as long as this is taken up, it will furnish an additional quantity of crystals of tartar emetic; and, finally, if the new mother-liquor be saturated with carbonate of potassa, it will furnish a fresh portion of the antimonial salt, after which the liquor is entirely exhausted. (*Journ. de Pharm.* xxvi. 136, *from the Annal. der Pharm.*) The oxychloride, as its name imports, contains a portion of sesquichloride. This is decomposed during the boiling, by means of the elements of water, into sesquioxide, which goes to form the tartar emetic, and muriatic acid which serves to hold in solution iron and other metallic impurities, which otherwise would fall and contaminate the crystals. Hence it is that the pure sesquioxide is not so well fitted for making tartar emetic as the oxychloride, in which the oxide is usefully associated with some sesquichloride.

In the *London* formula, the crocus is not prepared by a separate formula, but formed in the first part of the process. It is generated during the deflagration of equal weights of sesquisulphuret of antimony, and nitrate of potassa. The nitric acid of the nitre is decomposed, nitrogen and nitric

oxide being given off, and by furnishing oxygen to part of the sesquisulphuret, converts its constituents into sulphuric acid and sesquioxide of antimony. The sulphuric acid then combines with the potassa of the nitre, to form sulphate of potassa; while the sesquioxide unites or mixes with the undecomposed portion of the sesquisulphuret to constitute the crocus. From its constituents, therefore, the crocus may be called an oxysulphuret of antimony; but its composition is not uniform. The London formula is peculiar in directing the addition to the materials for deflagration, of a portion of muriatic acid, the object of which is to neutralize some free potassa, and either to prevent the formation of a portion of sulphuret of potassium, or immediately to decompose it, if formed, with the result of forming chloride of potassium. (*Phillips.*) The product of the deflagration is reduced to a very fine powder, and washed to remove the sulphate of potassa and chloride of potassium. The old plan of fusing this product, before reducing it to powder, is very properly avoided; as the fused crocus, from the difficulty of making it fine, is not readily soluble in the bitartrate of potassa. Crocus of antimony, as obtained by this process, is in the form of a saffron-brown powder, and contains only about $\frac{2}{3}$ ths of its weight of sesquioxide, the rest being sesquisulphuret, which is not available in the process, for forming the tartar emetic. By an approximate calculation, it may be assumed, from the quantities of sesquisulphuret of antimony and nitre taken in the formula, that 9 ounces of the washed crocus will be obtained, which is boiled with a little more than one and half times its weight of cream of tartar, and the solution filtered while hot. On the supposition that 9 ounces of crocus are formed, the quantity of water directed is large, being about 16 times the weight of the former. This amount may be necessary on account of the large proportion of insoluble sesquisulphuret of antimony present in the crocus.

Having given a sketch of the several officinal formulas, and of the proportions employed, it may be useful to present them in a tabular form. The sesquioxide is reduced to a common quantity, and the measures of water in the U. S., London, and Edinburgh Pharmacopœias are converted into the nearest corresponding weights.

AUTHORITY.	Form of Sesquioxide employed.	Proportion of Sesquioxide.	Proportion of Cream of Tartar.	Proportion of Water.
U. S. Pharm.	Oxychloride.	4	5	34
Dublin do.	Do.	4	5	34
Edinb. do.	Do.	4	5·7	33
London do.	Crocus.	4	6·2	65

It is seen by the table that the proportions of the U. S. and Dublin Pharmacopœias are identical. The proportion of cream of tartar increases, somewhat, in the Edinburgh formula, and still more in the London. It must be admitted, however, that the quantity of crocus generated by the London process is not precisely known, and may have been under-estimated. If so, the proportion of cream of tartar is given at too high a number.

In judging of the relative eligibility of these processes, several circumstances are to be taken into view. The cream of tartar should not be in excess; as in that case it is apt to crystallize upon cooling with the tartar emetic formed. To avoid such a result it is better to have a slight excess of antimonial oxide; and we are assured by Dr. Barker that the proportion of

4 of oxide to 5 of cream of tartar (U. S. and Dublin proportion) furnishes such an excess. According to Dr. Christison, however, the excess is too great; for upon making the experiment he found that there was a slight excess of antimonial oxide, even when using the larger proportion of cream of tartar directed in the Edinburgh Pharmacopœia. No rule is applicable to the determination of the proper proportion of water, except that it should be sufficient to dissolve the tartar emetic formed. The London Pharmacopœia employs a large quantity, and the probable reason why it is necessary has been suggested. The hot filtration directed may be conveniently performed by means of the tin apparatus, devised by Dr. Hare for filtering liquors at the point of ebullition. (See page 757 for a figure of this apparatus.) The U. S. and Edinburgh Pharmacopœias boil for an hour; the London and Dublin, for half an hour. In all cases the salt should be obtained in well defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists, of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.

The London College formerly used the glass of antimony for making tartar emetic, but have very properly laid it aside, on account of the difficulty of procuring it, and its liability to be mixed with glass of lead. On the last revision of their Pharmacopœia, they substituted the crocus, using a process which is characterized by Mr. Phillips as economical and easy of execution. Its economy, compared with the Edinburgh oxychloride process, is called in question by Dr. Christison, who tries it by the test of the relation of the cream of tartar expended to the sesquisulphuret employed. But here Dr. Christison has inadvertently made a miscalculation in assuming that 4 to $4\frac{1}{4}$ is in the proportion of 100 to 125. The true ratio between the sesquisulphuret and cream of tartar in the Edinburgh formula is as the numbers 100 to 106; while the ratio of the same substances in the London process is as 100 to 58. Thus, with the same expenditure of sesquisulphuret, the London College uses less cream of tartar, and consequently obtains less tartar emetic. But in making this comparison, the cost of all the materials must be taken into consideration; and if the London College uses a portion of nitre, and nearly twice as much sesquisulphuret as the Edinburgh College; on the other hand, it must be recollected that the latter College uses nearly 17 times as much muriatic acid as the former. Though the use of the crocus may not be objectionable on the score of expense, yet we think that the London College would have made a better choice, if they had substituted for the glass, the oxychloride rather than the crocus. The preference is given to the oxychloride by Berzelius; and M. Henry, an eminent pharmacist of Paris, after an elaborate comparison of the different processes in use for preparing tartar emetic, declares in favour of the one in which this oxide is employed. This testimony in favour of the Dublin process induced the revisers of our national Pharmacopœia to adopt it in 1830, and the Edinburgh College have judiciously substituted it for the crocus process, in their revision of 1839.

The French Codex uses the glass of antimony in preparing tartar emetic, and as the formula is somewhat peculiar, it may be useful to give it. According to the Codex, 300 parts of cream of tartar, in coarse powder, and 200 parts of the glass, in very fine powder, are boiled, in a silver or copper basin, with 2000 parts of water for half an hour, agitating continually, and replacing the water as it evaporates. The liquor is allowed to cool without filtering, and the crystals which form are removed, and washed repeatedly, by decantation,

with the mother-liquor. This is then filtered, and evaporated to dryness, and the residue exhausted by boiling water. The solution thus obtained is then filtered, and allowed to crystallize by cooling. The crystals obtained are all dissolved anew in boiling water, and the solution, after having been clarified with white of egg, is filtered, concentrated so as to mark 25° , and allowed to crystallize by slow cooling.

It has been already mentioned that M. Henry prefers the use of the oxychloride (*powder of Algaroth*) for making tartar emetic; in other words, the Dublin process. He has thought, however, that it was susceptible of some improvements, and has given a process on a large scale, which he prefers. As this formula may be useful to the manufacturing chemist, we subjoin it, turning the French weights into the nearest *apothecaries'* weights and measures. Take of prepared sulphuret of antimony, in very fine powder, three pounds four ounces; muriatic acid, marking 22° (sp. gr. 1.178), eighteen pounds and a half; nitric acid two ounces and a half. Introduce the sulphuret into a glass matrass, of a capacity double the volume of the mixture to be formed, and add to it from three to five pounds of the acids previously mixed, so that the sulphuret may be thoroughly penetrated by them, then add the remainder of the acids. Place the matrass on a sand-bath, and heat the mixture gradually to ebullition, avoiding the vapours, which are disengaged in large quantity. Continue the heat, until the vapours given off are so far deprived of sulphuretted hydrogen as not to blacken white paper moistened with solution of acetate of lead; after which allow the liquor to cool, and to remain at rest until it has become clear. Decant the clear liquid, and to obtain the portion of it which may be retained by the moist residue, mix this with a small portion of muriatic acid, and again decant. Mix the decanted liquids, which consist of a solution of sesquichloride of antimony, and add them to a large quantity of water, in order that the oxychloride may be precipitated; taking care, during their addition, to stir constantly in order that the precipitated powder may be more minutely divided, to facilitate its subsequent washing. To determine whether the water has been sufficient to decompose the whole of the sesquichloride, a part of the supernatant liquid, after the subsidence of the powder, is to be added to a fresh portion of water; and if a precipitate takes place, more water must be added to the mixture, so as to obtain the largest possible quantity of the oxychloride. The precipitation being completely effected, wash the powder repeatedly with water, until this no longer affects litmus, and then place it on linen to drain for twenty-four hours. The quantity of nitromuriatic oxide thus obtained will be about three pounds and a half in the moist state, or two pounds nine ounces when dry. Assuming it to be this quantity, mix it with three pounds eleven ounces of cream of tartar, in fine powder, and add the mixture to two gallons and five pints of boiling water, contained in an iron kettle. Concentrate the liquor rapidly until it marks 25° of Baumé's hydrometer for salts, and then filter. By repose, the liquor furnishes a crop of very pure crystals, which require only to be dried. The mother waters are treated in the following manner. Saturate the excess of acid with chalk, filter, and concentrate to 25° . By cooling, a second crop of crystals will be obtained; and by proceeding in a similar manner, even a third crop. But these crystals are somewhat coloured, and must be purified by recrystallization.

With regard to the above process, it may be observed, that the proportions of the cream of tartar and oxychloride must be adjusted according to the numbers given, on the assumption that the latter is dry; but it by no means follows that the whole of the oxide should be dried. To proceed thus would

cause a waste of time. The mode of proceeding is to weigh the whole of the moist oxide, and afterwards to weigh off a small part of it, and to ascertain how much this loses in drying. Then by a calculation it is easy to determine how much of the moist oxide must be taken, to be equivalent to a given weight of the dry.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; and it is not material what plan is adopted, provided the crystals of the antimonial salt are carefully purified. In an extensive manufactory in London, antimony ash is employed for boiling with the cream of tartar, and it is stated to form the cheapest material for making tartar emetic. (*Pereira, Mat. Med.*) The antimony ash is formed by roasting sesquisulphuret of antimony, and consists principally of sesquioxide and undecomposed sesquisulphuret. (*See page 105.*)

Properties, &c. Tartrate of antimony and potassa was discovered in 1631 by Adrian de Mynsicht. It is in the form of transparent, colourless crystals, which possess a nauseous, metallic, styptic taste, and have usually the form of rhombic octohedrons, the lateral planes of which are striated. When prepared from the oxychloride, it crystallizes in tetrahedrons, and the crystals are often an inch or more in diameter. As it occurs in the shops it is in the form of a white powder, resulting from the pulverization of the crystals. The crystals, when exposed to the air, effloresce slightly and become white and opaque. They are insoluble in alcohol, but dissolve in proof spirit or wine. (*See Vinum Antimonii.*) They are soluble in about fifteen parts of water at 60°, and in between two and three parts of boiling water. The late Dr. Perceval, of Dublin, alleged that good tartar emetic dissolves in twelve parts of water; and this statement agrees nearly with the result of Brandes, who found it to be soluble in 12.65 parts of water at 70°. Its aqueous solution slightly reddens litmus, and undergoes decomposition by keeping. When the salt is calcined in close vessels it yields a pyrophorus, consisting of an alloy of antimony and potassium. It is incompatible with acids, with alkalies and their carbonates, with some of the earths and metals, with chloride of calcium, and with acetate and subacetate of lead. It is incompatible also with astringent vegetable infusions and decoctions, such as of rhubarb, cinchona, catechu, galls, &c.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent.

Characteristics and Tests of Purity. Tartar emetic, when pure, exhibits its appropriate crystalline form. A crystal or two, dropped into a solution of hydrosulphuric acid, will become covered with an orange-coloured deposit of sesquisulphuret of antimony. Entire solubility in water is not a character belonging exclusively to the pure salt; for, according to Mr. Hennell, tartar emetic may contain ten per cent. of uncombined cream of tartar, and yet be wholly soluble in the proper proportion of water. (*Phillips.*) This being the case, the character, given in the U.S. and Edinburgh Pharmacopœias, of entire solubility in twenty parts of water is not to be depended upon. A dilute solution is not precipitated by chloride of barium or nitrate of silver, nor rendered blue by ferrocyanuret of potassium. A solution, containing one part of tartar emetic in forty of water, is not disturbed by an equal volume of a solution of eight parts of acetate of lead in thirty-two of water, and fifteen of acetic acid. This test is adopted in the U.S. Pharmacopœia from the Edinburgh, and is intended to show the absence of uncombined bitartrate of potassa; for when the acidulated acetate is used as here directed, it does not form the white tartrate of lead, except

with the tartaric acid of the bitartrate, when this happens to be present as an impurity. The acidulated acetate is a delicate test of this impurity, capable of detecting one per cent. of it in tartar emetic; but Dr. Christison finds difficulties in using it which render it too precarious for practice. Mr. Hennel's method of detecting uncombined bitartrate, is to add a few drops of a solution of carbonate of soda to a boiling solution of the antimonial salt, and if the precipitate formed is not redissolved, no bitartrate is present. (*Phillips*.)

The impurities found in tartar emetic are, uncombined cream of tartar from faulty preparation or fraudulent admixture, tartrate of lime, iron, sulphates, and chlorides. The mode of detecting cream of tartar has been indicated above. Tartrate of lime is derived from cream of tartar, which always contains this impurity. It is apt to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Iron is sometimes present, especially when the antimonial salt has been prepared from glass of antimony. It is detected by a blue colour being *immediately* produced by ferrocyanuret of potassium, added after a little acetic acid. If the blue colour be *slowly* produced, it may arise from reactions on the iron of the ferrocyanuret itself. If much iron be present, the solution of the tartar emetic will be yellow instead of colourless. Sulphates are detected by chloride of barium. The presence of a chloride is shown by a precipitate being produced by nitrate of silver, added to a dilute solution. According to Serullas, tartar emetic, except when well crystallized, and all the other antimonial preparations, usually contain a minute portion of arsenic, derived from the native sesquisulphuret of antimony, which almost always contains this dangerous metal. (For the mode of detecting it, see *Acidum Arseniosum*.) Tartar emetic is sometimes sold in powder to conceal its imperfections. It should never be bought in this state by the apothecary, but always in crystals, in which state the salt is pure, or very nearly so, and entirely free from arsenic. Its powder is perfectly white, and when yellowish-white, iron is probably present. It is said that some druggists ignorantly prefer a tartar emetic which is yellowish-white in powder.

It has been already stated in general terms, that tartar emetic in solution is incompatible with acids and alkalies, and with some of the earths; but this salt is so important, that some details in regard to the effects of particular reagents, included under these titles, seem to be necessary. Muriatic and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of subchloride or subsulphate of antimony mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of it. This effect of nitric acid is given by the London College as a character of good tartar emetic; but is certainly not very distinctive. When caustic potassa is added to a tolerably concentrated solution of the antimonial salt, it produces at first no effect, then a precipitate of sesquioxide, and afterwards the solution of this precipitate, if the addition of the alkali be continued. Lime-water acts in a weaker solution, and throws down a white precipitate, consisting of a mixed tartrate of lime and antimony. Carbonate of potassa affects still weaker solutions, throwing down a white precipitate of sesquioxide; but this test does not act in solutions containing less than a quarter of a grain of the antimonial salt to the fluidounce. Carbonate of ammonia also precipitates a solution of tartar emetic, throwing down a pure sesquioxide; and Dr. Barker, of Dublin, has proposed this method of obtaining the oxide, when wanted as a medicine. To these reagents may be added the infusion of galls, which, when fresh and strong, causes a dirty, yellowish-white precipitate of tannate of the sesquioxide of antimony.

Composition. Tartar emetic consists of two eqs. of tartaric acid 132·96, one of potassa 47·15, one of sesquioxide of antimony 153·2, and three of water 27=360·31. It is evident that it contains tartaric acid and potassa in the precise proportions to form bitartrate of potassa or cream of tartar; and accordingly, it may be viewed as a compound of one eq. of cream of tartar, and one of antimonial sesquioxide. The excess of acid in the bitartrate may be considered as united with the sesquioxide; and in that view it is a double salt, composed of the tartrate of potassa united with the tartrate of the sesquioxide of antimony. The name, therefore, of the U. S. and Dublin Pharmacopœias is correct.

Medical Properties and Uses. Tartrate of antimony and potassa is the most important of the antimonials, and is capable of fulfilling numerous indications in disease. Its general action is that of a sedative upon the circulation; while, on the contrary, it excites most of the secretions. According to the dose, and the peculiar circumstances under which it is administered, it acts variously, as an alterative, diaphoretic, diuretic, expectorant, purgative, and emetic. In minute doses, it is employed either alone, or conjoined with calomel, with a view to its alterative effects, and has been found useful in diseases of the skin. In small doses, mostly associated with saline remedies, such as nitre or sulphate of magnesia, and assisted by copious dilution, it is frequently resorted to in febrile complaints, for the purpose of producing perspiration, which is often copiously induced, especially if the remedy creates nausea. If the surface be exposed to cool air, so as to constrict the pores, the tendency will be to the kidneys, with the effect of producing an increased flow of urine. On the principle of exciting the secretions, it proves useful, on many occasions, in pulmonary and bronchial disease as an expectorant; and with a view to its action in this way, it is frequently conjoined with squill, ammoniac, and similar remedies. In full doses, it acts as an emetic, and as such is characterized by certainty, strength, and permanency of operation. It remains longer in the stomach than ipecacuanha, produces more frequent and longer continued efforts to vomit, and exerts a more powerful impression upon the system generally. The nausea and attendant prostration are often very considerable. As an emetic, its use is indicated where the object is not merely to evacuate the stomach, but to agitate and compress the liver and other abdominal viscera. By the extension of its action to the duodenum, it often causes copious discharges of bile, and hence forms an appropriate remedy in those diseases, in which there is an accumulation of that secretion. It is employed as an emetic in the commencement of fevers, especially those of an intermittent or bilious character, in jaundice, hooping cough, and croup, and in several diseases of the nervous system, such as mania, amaurosis, tic douloureux, &c. In efforts to reduce old dislocations, its relaxing power over the muscles, when acting as a nauseant, is taken advantage of, in order to facilitate the operation. As an incidental effect to its diaphoretic and emetic operation, tartar emetic often produces purging. Taking advantage of this tendency, practitioners are frequently in the habit of adding it to purgatives, the operation of which it promotes in a remarkable degree. It is contra-indicated in diseases of great debility, in the advanced stages of febrile affections, and in fevers attended with extreme irritability of stomach.

Of late years, on the continent of Europe, and to a certain extent in Great Britain and this country, tartar emetic has been given in large doses, with a view to its sedative, or as it is usually termed, *controstimulant* operation. This practice originated with Rasori, professor of clinical medicine at Milan, who published his views in 1800. The principal diseases in which it has

been thus used, are peripneumony, pleurisy, bronchitis, acute rheumatism, especially of the joints, articular dropsies, chorea, hydrocephalus, and apoplexy. The medicine is directed in doses, varying from a grain to two grains or more, every two hours, dissolved in a small quantity of water; the patient being restricted in the use of drinks whilst under its operation. It is stated that when the remedy is thus given in diseases of high action, it seldom produces vomiting, an effect which the authors of the practice wish to avoid. The power of the system to bear large doses of tartar emetic during the existence of acute disease, was considered by Rasori to depend upon the coexistent high morbid excitement, and the capability of bearing them was expressed by the term *tolerance*. It is in peripneumony especially that the controstimulant practice has most advocates. It is admitted to have the effect of lowering the force and frequency of the pulse and the rapidity of the respirations; and in not a few instances, it produces marked remedial effects. In pleurisy and bronchitis, the good effects of the same practice are less decided. Though we are disposed to admit the controlling influence of tartar emetic, when thus exhibited, in the diseases named, yet we by no means think that its use should supersede blood-letting, or even form our chief reliance. In cases, however, in which blood-letting, both local and general, has no effect, or has been carried as far as the circumstances of the case will permit, tartar emetic, administered on the controstimulant plan, may be found useful. If the tolerance cannot be otherwise established, laudanum may be conjoined with the antimony, in order to bring it about. In the treatment of articular dropsies, the decided benefit derived from large doses of tartar emetic, is fully shown by M. Gimelle, who has reported twenty-eight successful cases in support of the practice. The medicine was gradually increased from four grains to sixteen or twenty daily, and, generally, the tolerance was established on the first day. The effusion was absorbed in a space of time varying from eight to sixteen days. (*Amer. Journ. of Med. Sci. N. S.*, i. 520, from the *Bull. Gén. de Thérap.*)

Externally, tartar emetic is sometimes employed as a counter-irritant, mixed with lard or cerate, or sprinkled in very fine powder on adhesive plaster. (See *Unguentum Antimonii*.) It causes, after a longer or shorter interval, a burning sensation, accompanied by a peculiar and painful pustular eruption. This mode of producing counter-irritation is exceedingly serviceable in a number of diseases; but particularly in deep-seated pains, spinal irritation, whooping cough, and chronic inflammation of the chest threatening consumption. Care must be taken, when the salt is applied by means of a plaster, that the pustular inflammation does not proceed too far; as in that event, it produces deep and very painful ulcerations, difficult to heal. It acts by destroying the skin and subjacent cellular tissue in spots, but without being ordinarily absorbed.

Tartar emetic is generally given in solution, and in an amount which varies with the intention in view in its administration. Its dose as an alterative, is from the thirty-second to the twelfth of a grain; as a diaphoretic or expectorant from the twelfth to the sixth of a grain; and as a nauseating sudorific, from a quarter to half a grain; in each case, repeated once every one, two, or four hours. If required to act as a purgative, a grain may be dissolved in half a pint of water with an ounce of Epsom salt, and two tablespoonfuls of the solution given every two or three hours. As an emetic, the full dose is from two to three grains, though it is usually given in divided portions of a grain dissolved in a tablespoonful of water, every ten or fifteen minutes until it vomits, the operation being aided by warm water, or warm chamomile tea. It is often conjoined with ipecacuanha, in the proportion of one

or two grains to twenty of the vegetable emetic. For convenient administration in small doses, the Pharmacopœias order it dissolved in wine. (See *Vinum Antimonii*.) It is given very conveniently to children in dilute aqueous solution, which, being nearly tasteless, is readily taken by them.

Effects as a Poison. The effects produced by a poisonous dose of tartar emetic are an austere metallic taste; nausea; copious vomiting; frequent hickup; burning pain in the stomach; colic; frequent stools and tenesmus; fainting; small, contracted, and accelerated pulse; coldness of the skin; sometimes intense heat; difficult respiration; loss of sense; convulsive movements; very painful cramps in the legs; prostration; and death. To these effects is sometimes added difficulty of deglutition. Vomiting and purging in a few instances do not take place; and when they are absent, the other symptoms are aggravated. These are the effects produced on the healthy economy; but it has been fully proved that the doses which in a state of health would prove fatal, are sometimes borne without danger in certain morbid states of the system, attended with internal acute inflammation.

In treating a case of poisoning by tartar emetic, if it is found that the patient has not vomited, immediate recourse must be had to tickling the throat with a feather, and the use of abundance of warm water. Usually, however, the vomiting is excessive and distressing, and here it is necessary to use remedies calculated to decompose the poison, and to allay the pain and irritation. To effect the former object, astringent decoctions and infusions, such as of bark and common tea, are recommended as antidotes. These, however, act but imperfectly, according to the experiments of M. Toulmouche, who found that a decoction of cinchona had usually no power in lessening the emetic effect of this antimonial, though it had the property of decomposing the excess of the salt over a certain definite amount. (*Arch. Gén. 3ème Sér.*, ii. 363.) Similar observations have been made by Dr. Clutterbuck. (*Pereira*.) The decoction of galls acts more decidedly; but M. Toulmouche accords the preference to the galls given in substance, as an antidote in poisoning by tartar emetic. It no doubt acts by the tannic acid which it contains, and which forms, with the antimonial salt, the insoluble and probably inert tannate of antimony. To stop the vomiting and relieve pain, laudanum should be given, either by the mouth or injection, and to combat consecutive inflammation, bleeding, both local and general, and other antiphlogistic measures should be resorted to.

After death from suspected poisoning by tartar emetic, it is necessary to search for the poison in the body. The substances in the stomach should be digested in water, acidulated with a little muriatic and tartaric acid. The former acid will serve to coagulate some organic matter; the latter to give complete solubility to the antimony. The solution obtained, after having been filtered, is subjected to a stream of sulphuretted hydrogen, which will throw down the orange-red sesquisulphuret of antimony, distinguishable from the sulphuret of arsenic and all other precipitates by its forming with hot muriatic acid a solution, from which, when added to water, a white curdy precipitate of oxychloride of antimony is thrown down. Sulphuretted hydrogen is by far the most delicate test for tartar emetic.

Sometimes the antimony cannot be found in the stomach and bowels, and yet may exist in other parts. When it leaves the alimentary canal, it has been found by Orfila, especially in the liver and kidneys and their secretions. The mode of extracting the antimony, recommended by Orfila, is to carbonize the dried viscera with concentrated pure nitric acid in a porcelain capsule, to boil the charred mass obtained for half an hour with muriatic acid, assisted with a few drops of nitric acid, to filter the liquor, and

introduce it into Marsh's apparatus. Antimoniuretted hydrogen will be formed, which, being inflamed, will deposit the antimony on a cold surface of porcelain, as a black stain, distinguishable from the similar stain produced by arsenic by its less volatility, and by its forming with hot muriatic acid, a solution which affords a white precipitate when added to water. (See *Arch. Gén.*, 3ème Sér., vii. 511.)

VINUM ANTIMONII. *U. S.* VINUM ANTIMONII POTASSIO-TARTRATIS. *Lond.*; VINUM ANTIMONIALE. *Ed.* LIQUOR TARTARI EMETICI. *Dub.* *Antimonial Wine.*

"Take of Tartrate of Antimony and Potassa *a scruple*; Wine [Sherry] *ten fluidounces*. Dissolve the Tartrate of Antimony and Potassa in the Wine." *U. S.*

The *London* and *Edinburgh Colleges* direct *two scruples* of the salt to be dissolved in a *pint* [Imperial measure] of Sherry Wine. The *Dublin College* dissolves *one scruple* of the salt in *eight fluidounces* of boiling distilled water, and adds *two fluidounces* of Rectified Spirit.

In the first edition of the United States Pharmacopœia, the proportion of tartar emetic was four grains to the fluidounce of wine. In the revision of 1830, the quantity was reduced to two grains; and, as this is very nearly the proportion directed by the British Colleges, the highly important object has been accomplished, of uniformity in the strength of this very popular preparation. The seeming discrepancy between the formula of the *London* and *Edinburgh*, and that of the *U. S. Pharmacopœia*, will disappear when it is considered that the imperial pint, adopted by the two British Colleges, contains twenty fluidounces, each very nearly equal to the fluidounce of the ordinary apothecaries' measure. The *U. S.* officinal name was adopted as most convenient, sufficiently expressive, and in accordance with the nomenclature of several other metallic preparations, such as *Emplastrum Ferri*, *Mistura Ferri Composita*, &c.

Difficulty is often experienced in effecting a solution of tartar emetic in wine; and precipitation is very apt to occur after the solution has been effected. These results are attributable either to impurity in the antimonial salt, which frequently contains bitartrate of potassa and various insoluble substances, or to inferiority in the character of the wine, which holds in solution vegetable principles that form insoluble compounds with the sesquioxide of antimony. Dr. Paris states that he has seen the decomposition of the tartar emetic so complete, that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan, at one time directed, of first dissolving the antimonial in water, and then adding the wine; for even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and sound Sherry or Teneriffe wine, which make a permanent solution. To obviate the risk of decomposition and consequent inequality of strength, the *Dublin College* directs water and rectified spirit in about the proportions in which these exist in the wines just mentioned. The only objection to this menstruum is the want of colour, which renders the preparation liable to be confounded with less active liquids.

The advantages of antimonial wine are, that it affords the means of administering minute doses of tartar emetic, and is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is

usually administered in small doses as a diaphoretic or expectorant, or as an emetic in infantile cases. Where a considerable quantity of tartar emetic is requisite, it should always be given in extemporaneous aqueous solution. The dose of the wine as an expectorant or diaphoretic, is from ten to thirty drops, given frequently; as an emetic for children, from thirty drops to a fluidrachm, repeated every fifteen minutes till it operates. W.

ANTIMONII SULPHURETUM PRÆPARATUM. *Dub. Prepared Sulphuret of Antimony.*

“Take of Sulphuret of Antimony *any quantity*. Reduce it to powder, and separate for use the impalpable particles, in the manner directed for the preparation of Chalk.” *Dub.*

Sulphuret of antimony in mass is placed in the *Materia Medica* list of all the Pharmacopœias noticed in this work. But for use in medicine, and for some pharmaceutical processes, it requires to be in powder, and the above process is intended to effect this purpose. But it is hardly necessary to have a distinct formula to indicate the mode of proceeding, and accordingly this preparation has been expunged from the U. S. and Edinburgh Pharmacopœias. It was not included in the London.

Properties. Prepared sulphuret of antimony is in the form of an insoluble powder, without taste or smell; usually of a dull blackish colour, but, when perfectly pure, reddish-brown. By exposure to air, it absorbs, according to Buchner, a portion of oxygen, and becomes partially converted into sesquioxide. Its impurities and composition are mentioned under another head. (See *Antimonii Sulphuretum*.)

Medical Properties and Uses. This preparation is very uncertain in its operation; being sometimes without effect, at other times, if it meet with acid in the stomach, operating with extreme violence by vomiting and purging. The effects usually attributed to it are those of a diaphoretic and alterative; and the diseases in which it has been principally used, are scrofula, glandular obstructions, cutaneous diseases, and chronic rheumatism. It is not employed by physicians in the United States, its use in this country being exclusively confined to veterinary practice. The dose is from ten to thirty grains, given in powder or bolus.

ANTIMONII SULPHURETUM PRÆCIPITATUM. U. S. ANTIMONII OXYSULPHURETUM. *Lond.* ANTIMONII SULPHURETUM AUREUM. *Ed.* SULPHUR ANTIMONIATUM FUSCUM. *Dub.* *Precipitated Sulphuret of Antimony. Oxysulphuret of Antimony.*

“Take of Sulphuret of Antimony, in fine powder, *six ounces*; Solution of Potassa *four pints*; Distilled Water, Diluted Sulphuric Acid, each, *a sufficient quantity*. Mix the Sulphuret of Antimony with the Solution of Potassa and twelve pints of Distilled Water, and boil them over a gentle fire for three hours, constantly stirring, and occasionally adding Distilled Water so as to preserve the same measure. Strain the liquor immediately through a double linen cloth, and drop into it, while yet hot, Diluted Sulphuric Acid so long as it produces a precipitate; then wash away the sulphate of potassa with hot water, dry the Precipitated Sulphuret of Antimony, and rub it into a fine powder.” U. S.

“Take of Sesquisulphuret of Antimony, powdered, *seven ounces*; Solution of Potassa *four pints* [Imperial measure]; Distilled Water *two gallons* [Imp. meas.]; Diluted Sulphuric Acid *a sufficient quantity*. Mix the Sesquisulphuret of Antimony, Solution of Potassa, and Water together, and

boil with a slow fire for two hours, frequently stirring, Distilled Water being often added, that it may fill about the same measure. Strain the liquor, and gradually drop into it as much Diluted Sulphuric Acid as may be sufficient to throw down the Oxysulphuret of Antimony; then wash away the sulphate of potassa with water, and dry what remains with a gentle heat." *Lond.*

"Take of Sulphuret of Antimony, in fine powder, *an ounce*; Solution of Potash *eleven fluidounces* [Imperial measure]; Water *two pints* [Imp. meas.]. Mix the Water and Solution of Potash, add the Sulphuret, boil for an hour, filter immediately, and precipitate the liquid, while hot, with an excess of Diluted Sulphuric Acid. Collect the precipitate on a calico filter, wash it thoroughly with water, and dry it with a gentle heat." *Ed.*

"Take of Prepared Sulphuret of Antimony *one part*; Water of Caustic Potassa *eighteen parts*; Diluted Sulphuric Acid *eleven parts*, or a sufficient quantity. Add the Sulphuret of Antimony to the Water of Caustic Potassa, and boil for an hour. Strain the hot liquor through a double linen cloth, and drop into it the Diluted Sulphuric Acid. Wash away the sulphate of potassa with warm water. Dry the Brown Antimoniated Sulphur, and rub it into fine powder." *Dub.*

As the theory of the formation of the precipitated sulphuret of antimony is intimately connected with that of the production of the substances called *kermes mineral* and *golden sulphur*, we shall first describe the latter preparations as introductory to our account of the former.

Kermes mineral, according to Thenard, may be obtained by treating the sesquisulphuret of antimony in three ways; 1st with a boiling solution of the carbonated alkalies, 2d with a boiling solution of the caustic alkalies, and 3d with the carbonated alkalies at a red heat. These several processes give brown powders, which vary in their shade of colour, and which, though usually considered as identical, differ in composition. The kermes obtained by means of the carbonated alkalies is an oxysulphuret, that is, a mixture of sesquioxide of antimony with hydrated sesquisulphuret; while the product, when either the caustic alkalies, or the carbonated alkalies at a red heat are used, is essentially a hydrated sesquisulphuret, though containing occasionally a little oxysulphuret.

In France the process by the use of the carbonated alkalies in solution is preferred for preparing kermes; and the alkali selected is soda as giving a handsomer product. The formula of Cluzel is to boil for half an hour one part of pulverized sesquisulphuret of antimony with twenty-two or twenty-three parts of crystallized carbonate of soda, in two hundred and fifty parts of water, to filter the liquor, and receive it in warm earthen pans, which must be covered, and allowed to cool slowly. At the end of twenty-four hours, the kermes is deposited. It is then collected on a filter, washed with *boiled* water, cooled without contact of air, dried at the temperature of 77°, and kept in bottles well stopped. This formula is substantially the same with that given in the French Codex of 1837.

The rationale of the formation of kermes by this process is as follows. A portion of the carbonate of soda is converted by a transfer of carbonic acid, into caustic soda and sesquicarbonate. By a double decomposition taking place between a part of the sesquisulphuret of antimony and the caustic soda, sesquioxide of antimony, and sulphuret of sodium are formed. The sesquioxide then dissolves in the solution of the remaining carbonate of soda, and the undecomposed portion of the sesquisulphuret in that of the sulphuret of sodium. The sesquioxide and sesquisulphuret, being both more soluble in these menstrua hot than cold, precipitate together as the liquid cools, and constitute this variety of kermes. When thus obtained, it

is light, velvety, of a dark reddish-purple colour, brilliant in the sun, and of a crystalline appearance. It consists, according to M. Henry, jun., of sesquisulphuret of antimony 62·5, sesquioxide 27·4, water 10, and soda a trace; proportions which correspond most nearly with two eqs. of sesquisulphuret, one of sesquioxide, and six of water. In consequence of the presence of a considerable amount of sesquioxide of antimony in this variety of kermes, it must be far more active than the other kinds which contain comparatively little of this oxide. It ought, therefore, to be preferred for medical use.

Kermes, when obtained by means of the caustic alkalies, may be formed by boiling for a quarter of an hour, two parts of the sesquisulphuret of antimony with one part of caustic potassa dissolved in twenty-five or thirty parts of water, filtering the liquor, and allowing it to cool; whereupon the kermes precipitates. In this process, one portion of the sesquisulphuret, by reacting with a portion of the potassa, gives rise to sesquioxide of antimony and sulphuret of potassium. A second portion dissolves in the solution of sulphuret of potassium formed, and a third forms an insoluble compound with a part of the sesquioxide. The remainder of the sesquioxide unites with the potassa, forming a compound, which, being but sparingly soluble, is only in part dissolved. The hot filtered liquor, therefore, contains this compound dissolved in water, and sesquisulphuret of antimony dissolved in the solution of sulphuret of potassium. By refrigeration, the sesquisulphuret in a hydrated state falls down, free or nearly free from sesquioxide, this latter being still held in solution by means of the caustic alkali with which it is united.

Kermes is obtained by the third method, that is, in the dry way, by rubbing together two parts of sesquisulphuret of antimony and one of the potash of commerce, fusing the mixture in a crucible by a red heat, reducing the fused mass to powder, and boiling it with water. As the liquor cools the kermes is deposited. The rationale of its formation is nearly the same with that of the second variety of kermes. An inferior kermes, prepared in the dry way and intended for use in veterinary medicine, is directed in the French Codex to be prepared by fusing together, well mixed, 500 parts of sesquisulphuret of antimony, 1000 of carbonate of potassa, and 30 of washed sulphur, reducing the fused mass to powder, and boiling it with 10,000 parts of water. The liquor, upon cooling, lets fall the kermes, which must be washed with care and dried.

Kermes mineral is an insipid, inodorous powder, of different shades of brown. By the action of air and light it gradually becomes lighter coloured, and at last yellowish-white. It first came into use as a remedy in France about the beginning of the last century. Its mode of preparation was possessed as a secret by a French surgeon named La Ligerie. In 1720, the recipe was purchased by the French government and made public.

Golden sulphur is formed by the addition of an acid to the liquor which remains after the precipitation of the kermes. According to the directions of the French Codex, acetic acid is employed for this purpose. The liquor, when caustic potassa has been used, consists at first chiefly of sesquisulphuret of antimony, dissolved in solution of sulphuret of potassium, but in part also of sesquioxide, dissolved in solution of potassa. By the action of the air on the liquor, however, the sulphuret of potassium passes to a higher state of sulphuration; and consequently, the addition of an acid, while it throws down the sesquisulphuret and sesquioxide of antimony with disengagement of sulphuretted hydrogen, will precipitate at the same time the excess of sulphur in the sulphuret of potassium. Agreeably to this

explanation, golden sulphur is a mixed sesquisulphuret and sesquioxide of antimony containing more or less sulphur. It is in the form of a powder of a golden yellow colour. It may be worth while to mention that the kermes liquor, after the use of the carbonated alkalies, gives but little golden sulphur; while the liquors resulting from the two other processes yield it in abundance.

M. Musculus (*Journ. de Pharm. for May, 1836*) recommends the following process for preparing golden sulphur and kermes mineral by the method of displacement. He takes 6 parts of slaked lime, 4 of carbonate of potassa or of dried carbonate of soda, 2 of finely powdered sesquisulphuret of antimony, 1 of flowers of sulphur, and 8 of well washed and dried sand. These are accurately mixed and put into a glass or stoneware displacement apparatus, the bottom of which is covered with little pebbles, or coarsely powdered glass. (See page 763.) The mixture being covered with a layer of sand, cold water is poured upon it until the liquor which passes is no longer precipitated by muriatic acid. The liquor obtained is then diluted with pure water, and treated with muriatic acid, which throws down the golden sulphur. This is carefully washed and dried, and amounts to about the quantity of sesquisulphuret employed. In preparing the kermes the same method is pursued, except that the sulphur is omitted and the liquor obtained precipitated by a solution of bicarbonate of soda.

M. Boullay, who repeated the above process, speaks of it with commendation, as enabling the apothecary to operate on a small scale, and without the employment of heat. The golden sulphur was very handsome, but the kermes was heavy and imperfect in colour. These defects in the latter, he found might be remedied by using exclusively the dried carbonate of soda, and by diluting the liquid with an equal volume of river water, deprived of air by boiling before precipitating. The kermes thus obtained was abundant, light, and of a very intense and beautiful colour. The editors of the *Annalen der Pharmacie* also repeated the process with good results. They remark, however, that it is indispensable that the sand employed should be free from iron.

From the explanations which have been given, the reader is prepared to understand that the method of preparing the precipitated sulphuret of antimony of the United States and British Pharmacopœias, combines the process for forming the kermes mineral by means of a *caustic alkali*, with that for obtaining golden sulphur; for while the refrigeration of the solution acting alone would cause the precipitation of this variety of kermes, which contains little or no antimonial oxide, the sulphuric acid added would throw down more or less of the golden sulphur. But the question here arises how far this golden sulphur would be identical with that obtained from the mother-liquor of kermes which has been some time made. From the explanations given above in relation to golden sulphur, it may be inferred as probable that the precipitate by acids, if thrown down immediately while the solution is hot as directed by the Pharmacopœias, and before the air has had time to act, would consist exclusively of sesquisulphuret and sesquioxide; but if thrown down from the kermes mother-liquor, would contain more or less free sulphur, according as the liquor had been more or less subject to the influence of the air. If these views be admitted, then the so called golden sulphur must be a very variable preparation as to the free sulphur it contains, dependent upon the greater or less change which the kermes liquor may have undergone, before being used for furnishing the precipitate.

Properties of the Precipitated Sulphuret. This substance is a bright

orange-coloured insoluble powder, tasteless when pure, but having usually a slightly styptic taste. The greater portion of it is not readily acted on by dilute acids. When it contains no free sulphur it is wholly soluble in nitro-muriatic acid, with the escape of sulphuretted hydrogen. If free sulphur be present, it will be left behind. If it effervesce with diluted sulphuric acid, its adulteration with chalk may be suspected. Recently prepared it is completely soluble in the officinal solution of potassa, but as it is found in the shops, a white residuum is usually left undissolved. When boiled with a solution of cream of tartar, about 12 per cent. of sesquioxide is dissolved. Exposed to heat it takes fire, burning with a greenish-blue flame and giving off sulphurous acid, while the metal remains behind in the state of a grayish oxide. Precipitated sulphuret of antimony, as analyzed by Mr. Phillips, consists, in the 100 parts, of sesquisulphuret 76·5, sesquioxide 12, and water 11·5; corresponding most nearly with five eqs. of sesquisulphuret, one of sesquioxide, and sixteen of water. It usually, however, contains a portion of free sulphur, as shown by the action of nitro-muriatic acid. Its active ingredient is the sesquioxide; and in reference to its presence, the London College calls the preparation oxysulphuret of antimony. The Edinburgh College names it incorrectly, *golden sulphuret of antimony*; this name being properly applicable to the precipitate produced by the sole action of acids, and not to it when obtained by the action of acids and refrigeration conjointly.

Medical Properties. The precipitated sulphuret is alterative, diaphoretic and emetic. It is, however, an uncertain medicine, as well from the want of uniformity in its composition, as from its liability to vary in its action with the state of the stomach. It is seldom given alone, but generally in combination with calomel and guaiac, in the form of Plummer's pill, as an alterative in secondary syphilis and cutaneous eruptions, or conjoined with henbane or hemlock in chronic rheumatism. (See *Pilulæ Hydrargyri Chloridi Compositæ*.) During its use the patient should abstain from acidulous drinks. Its dose as an alterative is from one to two grains twice a day in the form of pill; as an emetic, from five grains to a scruple. The *kermes* obtained by means of the carbonated alkalies, as it contains between two and three times as much sesquioxide as the precipitated sulphuret, is a more active preparation, and must be used in a smaller dose. This latter is sometimes used in large doses as an antiphlogistic in peripneumony and other inflammations of the chest.

Off. Prep. *Pilulæ Hydrargyri Chloridi Comp., Lond., Ed., Dub. B.*

PULVIS ANTIMONIALIS. *Ed., Dub.* **PULVIS ANTIMONII COMPOSITUS.** *Lond.* *Antimonial Powder. Compound Powder of Antimony.*

“Take of Sesquisulphuret of Antimony, powdered, *a pound*; Horn shavings *two pounds*. Mix, and throw them into a red-hot crucible, and stir constantly until vapour ceases to arise. Rub the residue to powder, and put it into a proper crucible. Then apply heat, and raise it gradually to redness, and keep it so for two hours. Rub the residue into a very fine powder.” *Lond.*

“Take of Sulphuret of Antimony, in coarse powder, Hartshorn shavings, *equal weights*. Mix them, put them into a red-hot iron pot, and stir constantly till they acquire an ash-gray colour, and vapours no longer arise. Pulverize the product, put it into a crucible with a perforated cover, and expose this to a gradually increasing heat till a white heat is produced, which is to be maintained for two hours. Reduce the product when cold to fine powder.” *Ed.*

The *Dublin College* use the proportions of the London formula, taking their prepared sulphuret, but treat the materials in the manner directed in the *Edinburgh Pharmacopœia*.

This preparation consists mainly of bone-phosphate of lime, or bone-earth, mixed with antimonious acid, and is intended to furnish a substitute for the celebrated empirical remedy of Dr. James, an English physician who died in 1776, and after whom the original composition was called *James's powder*. Dr. Pearson, of London, found the genuine powder, on analysis, to consist of phosphate of lime and oxidized antimony, and, guided by his results, devised the formula adopted by the British Colleges for producing an imitation of it. By burning the materials directed, while they are constantly stirred, the sulphur is expelled in the form of sulphurous acid, and the antimony oxidized; while the hartshorn, which is of the nature of bone, has its animal matter converted into charcoal. By the subsequent calcination, the charcoal is dissipated, leaving only the phosphate of lime mixed with the oxidized antimony. This mixture constitutes the antimonial powder. The only material difference between the processes of the Colleges is that the London and Dublin use two parts of horn shavings to one of sulphuret; while the Edinburgh College employs equal weights, which are also the proportions adopted in the French Codex. The use of the larger proportion of horn is said to obviate the inconvenience of the vitrification of part of the antimony; but the late Dr. Duncan alleged that the product thus obtained did not correspond so well with James's powder, as analyzed by Dr. Pearson, as when the smaller proportion was employed.

In consequence of the variable nature of antimonial powder, as obtained in the processes of the Colleges by the agency of fire, Mr. Chenevix proposed to form it in the humid way, by dissolving equal weights of oxychloride of antimony (*powder of Algaroth*) and precipitated phosphate of lime in the smallest possible quantity of muriatic acid, and precipitating this solution by adding it to diluted water of ammonia. The solvent power of the muriatic acid being destroyed by its union with the ammonia, the sesquioxide of antimony and phosphate of lime are thrown down in determinate proportions, and in a state of intimate mixture. This precipitate, Mr. Chenevix states, is soluble in any acid capable of dissolving its constituents separately. On the other hand, 28 per cent. of James's powder, and about 44 per cent. of the London Antimonial powder, resist the action of all acids. It is hence evident that Mr. Chenevix's powder would prove far more active than those for which it is proposed as a substitute. This objection to it might be obviated by increasing the proportion of phosphate of lime; but still it is liable to the defect, according to Mr. Brande, of becoming horny or gritty, and of being difficult to pulverize.

Properties, Composition, and Tests. This preparation is a tasteless, inodorous, gritty powder, of a dull-white colour. As often prepared it is insoluble in water; but usually a small portion, consisting of antimonite and superphosphate of lime, dissolves in boiling distilled water. Its composition varies exceedingly, a circumstance which forms a strong objection to it as a medicine. When entirely insoluble in boiling water, it probably contains nothing but antimonious acid and phosphate of lime; for when its soluble constituents are absent, the sesquioxide is absent also. The best samples, as stated by the Edinburgh College, are formed of "a mixture chiefly of antimonious acid and phosphate of lime, with some sesquioxide of antimony, and a little antimonite of lime." To these ingredients may be added superphosphate of lime, which was found in small quantity by Dr. D. MacLagan of Edinburgh. This writer obtained in his experiments about 50 per cent. of anti-

monious acid, 45 of phosphate of lime, nearly 4 of sesquioxide, and not quite 1 of antimonite and superphosphate of lime. In testing the goodness of the preparation, the first step is to act on it with boiling distilled water. If any antimonite should be dissolved, the solution will form with sulphuretted hydrogen an orange-coloured precipitate of bisulphuret of antimony; if superphosphate be present, nitrate of silver will throw down phosphate of silver. What remains of the powder, unacted on by the distilled water, is next digested with muriatic acid, which will dissolve the phosphate of lime, and also sesquioxide of antimony if present, and leave a residue which is the antimonious acid. If sesquioxide is present in the muriatic solution, it will be precipitated by sulphuretted hydrogen, as an orange-coloured sesquisulphuret, and from the filtered solution, water of ammonia will throw down the phosphate of lime. In this way all the ingredients of antimonial powder may be detected and separated. It might be supposed that the muriatic solution would be more readily tested for the presence of sesquioxide by the action of water, which is known to cause a white precipitate of the oxide in this solution; but there appears to be some ambiguity in relation to the action of water. The Edinburgh College, in their formula of tests, state that the muriatic solution of the residue, after the action of water, does not become turbid by dilution; but, according to Dr. Barker and Dr. Pereira, this effect sometimes takes place. These different results may be explained by the different qualities of the preparation. A small quantity of sesquioxide may be in the muriatic solution, and yet not be precipitated by water; while a larger quantity will be so precipitated. On the other hand a precipitate may be produced with water, without its proving the presence of sesquioxide; for unless the antimonial powder be most carefully exhausted by the distilled water, before being subjected to the acid, the muriatic solution may contain antimonite of lime which, like the sesquioxide, gives it the property of becoming turbid with water.

Medical Properties and Uses. This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it may be given. Until within a few years it was frequently used in febrile diseases, with a view to its diaphoretic effect. According to Dr. A. T. Thomson, it is advantageously given in acute rheumatism, conjoined with camphor, calomel, and opium, and with calomel and guaiac in several cutaneous affections. The estimation in which this preparation is held is very various. The late Dr. Duncan characterized it as one of the best antimonials we possess; yet he acknowledged that its effects are very unequal, either from idiosyncrasy, or variations in its composition. Dr. Thomson found it sometimes to answer his expectations, but as often to disappoint them. Mr. Brande admits its activity sometimes, and entire inertness at others, differences which he attributes to the presence or absence of *sesquioxide* of antimony. Upon the whole it appears that, whatever may be the occasional efficacy of this medicine, it is too variable in its composition, from circumstances in its preparation scarcely within the control of the pharmaceutical chemist, to make it a safe remedy. No therapeutical effect can be expected from it, which cannot be more certainly and safely produced by tartar emetic; and it seems to be the sentiment of some of the best practitioners, that antimonial powder may very well be dispensed with as a remedy. Considerations of this kind caused it to be omitted from the U. S. Pharmacopœia upon the revision of 1830.

The dose of antimonial powder as a diaphoretic, is from three to eight grains every third or fourth hour, given in the form of pill. In larger doses

it is purgative or emetic. It is impossible, however, to give precise directions as to the dose; as it sometimes proves violently emetic in moderate doses, and at other times produces no obvious effect, even in doses of 100 grains.

AQUA.

Water.

AQUA DESTILLATA. *U.S., Lond., Ed.* AQUA DISTILLATA. *Dub. Distilled Water.*

"Take of Water *ten gallons*. First distil *two* pints, and throw them away; then distil *eight* gallons. Keep the distilled Water in glass bottles." *U.S.*

The *London* formula is the same as the above.

"Take any convenient quantity of spring Water; distil it from a proper vessel, rejecting the first twentieth part, and preserving the first half of the remainder." *Ed.*

"Take of Water *twenty pounds*. Put it into a glass retort, and having rejected the first pound which comes over, distil a gallon with a moderate heat." *Dub.*

The purest natural water is not sufficiently pure for some pharmaceutical purposes; and hence the necessity of the above processes for its distillation. It is best to reject the first portion which comes over, as this may contain carbonic acid and other volatile impurities; and the last portions of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The Dublin College directs the distillation to be conducted in a glass retort; but it is usually performed with the ordinary still and condenser, and such an apparatus is evidently contemplated in the United States and London formulæ. Mr. Brande states that distilled water often derives from the still a foreign flavour, which it is difficult to avoid. He, therefore, recommends that a still and condenser be exclusively kept for distilling water; or, where this cannot be done, that steam be driven through the condensing pipe for half an hour, for the purpose of washing it out before it is used; the worm-tub having been previously emptied.

Properties, &c. Distilled water, as usually obtained, has a vapid and disagreeable taste. It is not perfectly pure; water, to be so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua*. Distilled water should undergo no change by sulphuretted hydrogen, or on the addition of tincture of soap, subacetate of lead, chloride of barium, oxalate of ammonia, nitrate of silver, or lime-water. It is uselessly employed in some formulæ, but is essential in others. As a general rule, when small quantities of active remedies are to be given in solution, and in the preparation of collyria, distilled water should be employed. The following list contains the chief substances which require distilled water as a solvent;—tartar emetic, corrosive sublimate, nitrate of silver, chloride of barium, acetate and subacetate of lead, the sulphates of iron and zinc, sulphate of quinia, and the sulphate, muriate, and acetate of morphia.

B.

AQUÆ MEDICATÆ. U.S.

Medicated Waters.

Under this head are included, in the United States Pharmacopœia, all those preparations consisting of water impregnated with some medicinal substance, which are not arranged in any other class. Among them are the Distilled Waters of the British Pharmacopœias, which therefore require some notice in the present place.

AQUÆ DESTILLATÆ. *Lond.* AQUÆ DISTILLATÆ. *Dub.* DISTILLED WATERS. *Ed.*

“Distilled waters may be prepared from fresh, and generally also from dried, vegetables. In the latter case only half the weight of material should be used. They may also be prepared, for the most part, by agitating the volatile oils of the plants with water and filtering the solution. But distilled waters obtained in this way have seldom so fine a flavour as those obtained from the plants themselves.” *Ed.*

Many vegetables impart to water distilled from them their peculiar flavour, and more or less of the medical properties by which they are distinguished. The distilled waters chiefly used are those prepared from aromatic plants, the volatile oil of which rises with the aqueous vapour, and is condensed with it in the receiver. But as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed rather as pleasant vehicles or corrigents of other medicines, than with a view to any remediate action of their own.

In the preparation of the distilled waters, dried plants are sometimes used, because the fresh are not to be had at all seasons; but the latter, at least in the instances of herbs and flowers, should be preferred if attainable. Flowers which lose their odour by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state, according to M. Decroizilles, afford distilled waters of very delicate flavour.

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previously to the operation. The quantity of materials should not bear too large a proportion to the capacity of the alembic, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state till the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the vegetable matter, lest a portion of the latter, coming in contact with the sides of the vessel, might be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously or carried too far, a slimy matter is apt to form, which adheres to the sides of the alembic above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil-bath regulated by a thermometer, or of a bath of solution of chloride of calcium, by which any temperature may be obtained between 212° and 270°, according to the strength of the solution; or, when the process is conducted upon a large scale, by means of steam introduced under pressure into a space around the still. If any volatile oil float upon the surface of the distilled water, it should be separated.

But, however carefully the process may be conducted, the distilled waters

prepared from plants always have at first an unpleasant smoky odour. They may be freed from this by exposure for a short time to the air, before being enclosed in well-stopped bottles, in which they should be preserved. When long kept, they are apt to form a viscid ropy matter, and to become sour. This result has been ascribed to other principles, which rise with the oil in distillation, and promote its decomposition. To prevent this decomposition, the *London College* orders proof spirit, and the *Edinburgh* rectified spirit, to be added to the water employed in the process of distillation. For the same purpose, the *Dublin College* directs half an ounce of rectified spirit to be added to each pound of the distilled water. But this addition is inadequate to the intended object. A better plan is to redistil the waters; as, when thus purified, it is said that they may be kept for several years unchanged.

Robiquet considers the mucosity which forms in distilled waters as the result of a vegetative process, to which the presence of air is essential. He has found that, so long as the water is covered with a layer of essential oil, it undergoes no change; but that the oil is gradually altered by exposure to the air, and as soon as it disappears, the water begins to be decomposed. He states that camphor exercises the same preservative influence over the distilled waters by resisting the vegetation, and that those in which the odour of camphor is developed keep better on this account. Finally, he has observed that the more distilled water is charged with volatile oil, the more abundant is the mucosity, when it has begun to form. Robiquet unites with Henry and Guibourt, and with Virey, in recommending that all these waters, when intended to be kept for a considerable time, should be introduced, immediately after distillation, into bottles of a size proportionate to the probable consumption of the water when brought into use; and that the bottles should be quite filled, and then sealed or otherwise well stopped, so as entirely to exclude the air. Thus treated, they may be preserved without change for many years. (*Journ. de Pharm.* xxi. 402.)

Another mode of preparing the distilled waters is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed by the *London* and *Dublin Colleges* in several instances. It is said to afford a more permanent product than the preceding; but does not always preserve the flavour of the plant.

In relation to most of the aromatics, the *United States Pharmacopœia* discards altogether the process by distillation, and directs that water should be impregnated with the volatile oil by trituration with carbonate of magnesia, and subsequently filtered. This is by far the most simple and easy process; and the resulting preparation is in all respects equal to that obtained by distillation from the oil. The aromatic solution is pure and permanent, and is perfectly transparent, the carbonate of magnesia being separated by the filtration. The carbonate of magnesia is preferable to the pure earth; as the latter sometimes gives a brownish colour to the liquid, and requires to be used in larger proportion. A minute quantity, moreover, of the magnesia is dissolved, and, attracting carbonic acid from the air, becomes a carbonate, and is precipitated in a flocculent form. Besides, it would prove incompatible with small quantities of sulphate of morphia and certain metallic salts given in minute doses, as bichloride of mercury and nitrate of silver. The object of the magnesia or its carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. Chalk and sugar answer a similar purpose; but the latter, by being dissolved with the oil, renders the preparation impure.

We are pleased to find that the *London College*, in the edition of their

Pharmacopœia for 1836, recognise the above mode of preparing the distilled waters. After directions for preparing them severally by distillation, they state that "Several of the DISTILLED WATERS may be prepared in a very short time, when wanted for more speedy use, by carefully rubbing a *drachm* of any distilled oil with a *drachm* of Carbonate of Magnesia, and then with *four pints* [Imperial measure] of Distilled Water, and finally filtering the liquor." W.

AQUA ACIDI CARBONICI. *U. S. Carbonic Acid Water. Artificial Seltzer Water.*

"By means of a forcing pump, throw into a suitable receiver, nearly filled with Water, a quantity of Carbonic Acid equal to five times the bulk of the Water. Carbonic Acid is obtained from Marble by means of dilute Sulphuric Acid." *U. S.*

This preparation, which is peculiar to the United States Pharmacopœia, consists of water highly charged with carbonic acid. Water is found to take up its volume of this acid under the pressure of the atmosphere; and Dr. Henry ascertained that precisely the same *volume* of the *compressed* gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. A double pressure will force a double quantity into a given space, and, therefore, cause a double quantity to be absorbed; a treble pressure will drive a treble quantity into the same space, and cause its absorption; and so on for higher pressures, the *bulk* of the *compressed* gas absorbed always remaining the same. From the principles above laid down it follows, that, to saturate water with five times its volume of carbonic acid, as directed in the formula, it must be subjected to a pressure of five atmospheres; and this is about the strength of the carbonic acid water manufactured in the United States.

Carbonic acid water is familiarly called in this country "mineral water," and "soda water;" the latter name, originally applied to the preparation when it contained a small portion of carbonate of soda, being from habit continued since the alkali has been omitted. As it is largely consumed, both as an agreeable beverage and as a medicine, it will be proper to give a sketch of the apparatus usually employed in its preparation. This consists of a generator, gasometer, forcing pump, reservoir or fountain, and refrigerator. The generator is usually formed of a wooden tub somewhat like a churn, into which the dilute sulphuric acid is put. On this is luted a small cylindrical wooden vessel, through the bottom of which passes a wooden stirrer. This vessel is filled with marble powder, which, by the movement of the stirrer, is made gradually to fall into the acid below, generating the carbonic acid, which by a lead pipe is conducted into the gasometer. This is a large cylindrical tub, in which another is inverted suspended by a pulley. As soon as the gasometer is full, which should have five or six times the capacity of the reservoir, the operation of condensing the gas into the latter is commenced. This is effected by a condensing pump, the chamber of which is made to communicate, by leaden tubes on opposite sides, with the gasometer and reservoir. The latter, usually called the fountain, is a very strong cylindrical copper vessel, with hemispherical extremities, tinned on the inside, and, before receiving the carbonic acid, nearly filled with water. When the water has been duly charged with the acid gas, it is drawn off as it is wanted, by means of a stop-cock connected with a tube

which passes to the bottom of the reservoir. The tube may be of any desired length, so as to draw off the water at a distance from the reservoir. The apparatus is usually placed in the cellar, and the tube from the reservoir is made to pass through the floor and counter of the shop, and to terminate in a stop-cock, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool in summer, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, placed under the counter and surrounded with ice, and from this vessel a separate tube penetrating the counter proceeds.

The acid gas for the impregnation of the water is always obtained from marble dust by the action of sulphuric acid; these being the cheapest materials for the purpose. Chalk may also be used, but is objectionable on account of its communicating an unpleasant smell to the carbonic acid. When sulphuric acid is employed, sulphate of lime is formed, which interferes with the action of the acid; and hence it is necessary to stir the mixture to render the decomposition of the carbonate complete.

Properties. Carbonic acid water is a sparkling liquid, possessing an agreeable, pungent, acidulous taste. It reddens litmus feebly, and is precipitated by lime-water. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its briskness, it should be kept in strong well corked bottles, placed inverted in a cool place. Several natural waters are of a similar nature; such as those of Seltzer, Spa, and Pyrmont; but the artificial water has the advantage of a stronger impregnation with the acid gas. Carbonic acid water, when pure, is not discoloured by sulphuretted hydrogen or solution of ammonia, and yields no precipitate with sulphate of soda or ferrocyanuret of potassium. It should be made with every precaution to avoid metallic impurity. Hence the necessity of having the reservoir or fountain well tinned on the inner surface. Even with this precaution, a slight metallic impregnation is not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the reservoir. Glass fountains are sometimes used with advantage at this season; and a patent has been taken out for a stoneware fountain enclosed in tinned copper, which has been found to answer a good purpose. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. A case of colica pictonum occurred to one of the authors, arising from the daily use of the first draught of carbonic acid water from a fountain furnished with tubes of lead. Tin tubes are sometimes employed, enclosed in lead ones to give them strength.

Carbonic acid, formerly called *fixed air*, is a colourless gas, of a slightly pungent odour and acid taste. It reddens litmus feebly, and combines with salifiable bases, forming salts called carbonates, from which it is expelled by all the strong acids. It extinguishes flame, and is quickly fatal to animals when respired. All kinds of fermented liquors, which are brisk or sparkling, such as champagne, cider, porter, &c., owe these properties to its presence. Its sp. gr. is 1.52. In 1823 it was liquified by Faraday by a pressure of 36 atmospheres, and in 1836 solidified by Thilorier, by taking advantage of the cold generated by the sudden gasefaction of the liquid acid, when freed from pressure. It is composed of one eq. of carbon 6.12, and two of oxygen 16=22.12.

Carbonic acid gas has been used by Professor Mojon, of Geneva, as an injection in dysmenorrhœa with the most soothing effects. It is applied by means of a flexible tube, inserted into the vagina, and proceeding from a

bottle containing pieces of chalk and dilute sulphuric acid. The application is continued for five minutes, and repeated several times a day. (*Am. Journ. of the Med. Sci.* xxii. 469, from the *Bull. Gén. de Thérap.*)

Medical Properties and Uses. Carbonic acid water is diaphoretic, diuretic, and anti-emetic. It forms a very grateful drink to febrile patients, allaying thirst, lessening nausea and gastric distress, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, sulphate of magnesia, and the saline cathartics generally; rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces will be sufficient. B.

AQUA ANETHI. *Lond., Ed. Dill Water.*

"Take of Dill [fruit], bruised, a pound and a half; Proof Spirit seven fluidounces; Water two gallons [Imperial measure]. Distil a gallon." *Lond.*

The *Edinburgh College* takes the same quantity of dill and of water, with three fluidounces of rectified spirit, mixes, and distils a gallon.

This is seldom if ever used in the United States. W.

AQUA CAMPHORÆ. U.S. MISTURA CAMPHORÆ. *Lond., Ed., Dub. Camphor Water.*

"Take of Camphor two drachms; Alcohol forty minims; Carbonate of Magnesia a drachm; Distilled Water two pints. Rub the Camphor first with the Alcohol, afterwards with the Carbonate of Magnesia, and lastly with the Water gradually added; then filter through paper." *U. S.*

The *London College* takes half a drachm of camphor, ten minims of rectified spirit, and a pint [Imperial measure] of water; rubs the camphor first with the spirit, and then with the water gradually added; and strains through linen. The *Dublin College* orders a scruple of camphor, ten drops of alcohol, a pint of warm water, and, instead of the carbonate of magnesia, half an ounce of sugar; and completes the process as directed in the *U. S. Pharmacopœia*. The *Edinburgh College* directs a scruple of camphor and half an ounce of sugar, well rubbed together, to be beat, with half an ounce of blanched sweet almonds, into a smooth pulp; a pint [Imp. meas.] of water to be gradually added, and the mixture to be strained.

In all these processes the object is to effect a solution of the camphor. Water is capable of dissolving but a small proportion of this principle; but the quantity varies with the method employed. The *London* preparation is very feeble. Made according to the *Edinburgh* and *Dublin* processes, one pint of the water contains less than twenty grains of camphor; while our own officinal preparation contains about fifty grains to the pint, or more than three grains to the fluidounce. (*Journ. of the Phil. Col. of Pharm.* iv. 13.) The difference is attributable to the minute division effected in the camphor by trituration with the carbonate of magnesia, which is afterwards separated by filtration. The use of the alcohol is simply to break down the cohesion of the camphor, and enable it to be more easily pulverized. The process of the *U. S. Pharmacopœia* is much preferable to the others, as it affords a permanent solution of sufficient strength to be employed with a view to the influence of the camphor on the system; while the *British* preparations have little more than the flavour of the narcotic, and are fit only for vehicles of other medicines. The camphor is separated by a solution of pure potassa, and, according to *Dr. Paris*, by sulphate of magnesia and several other salts.

Camphor water is chiefly employed in low fevers and typhoid diseases attended with restlessness, slight delirium, or other symptoms of nervous derangement or debility. It is used also to allay uterine after-pains. It has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is not applicable to cases where very large doses of the medicine are required. It is usually given in the dose of one or two tablespoonfuls repeated every hour or two hours. W.

AQUA CARUI. *Lond., Dub. Caraway Water.*

The *London College* prepares this in the same manner as *Dill Water*. (See *Aqua Anethi*.) The *Dublin College* takes a pound of bruised caraway seeds, and sufficient water to prevent empyreuma, and distils a gallon.

Caraway water has the flavour and pungency of the seeds, but is not used in this country. W.

AQUA CASSIÆ. *Ed. Water of Cassia.*

"Take of Cassia-bark, bruised, *eighteen ounces*; Water, *two gallons* [Imperial measure]; Rectified Spirit *three fluidounces*. Mix them together, and distil off one gallon." *Ed.*

The distinction between cassia and cinnamon is not recognised in our Pharmacopœia; so that this preparation would rank as a variety of cinnamon water. (See *Aqua Cinnamomi*.) W.

AQUA CHLORINII. *Dub. CHLORINEI AQUA.* *Ed. Chlorine Water.*

"Take of dried Muriate of Soda *one hundred parts*; Oxide of Manganese *thirty parts*; Sulphuric Acid *eighty-seven parts*; Water *one hundred and twenty-four parts*. Add the Acid gradually to the Water, and when the mixture has grown cold, pour it on the Muriate of Soda and Oxide of Manganese, reduced to fine powder, well mixed, and put into a retort. Then with a proper apparatus and a moderate heat gradually increased, transmit the gas escaping from the mixture through *two hundred parts* of Distilled Water; the operation being concluded as soon as the effervescence in the retort has ceased. Chlorine Water should be kept in well stopped glass bottles, and in a place impervious to the rays of light." *Dub.*

"Take of Muriate of Soda *sixty grains*; Sulphuric Acid (commercial) *two fluidrachms* [Imperial measure]; Red Oxide of Lead *three hundred and fifty grains*; Water *eight fluidounces* [Imp. meas.]. Triturate the Muriate of Soda and Oxide together; put them into the Water contained in a bottle with a glass stopper; add the Acid; agitate occasionally till the Red Oxide becomes almost all white. Allow the insoluble matter to subside before using the liquid." *Ed.*

These formulæ are intended to furnish a saturated solution of chlorine in water. The materials employed by the *Dublin College* are those usually taken for generating chlorine; and this, as it is extricated in a gaseous state, is passed into a portion of water, with a view to its being absorbed. Muriate of soda is the chloride of sodium of modern chemists. This, when acted on by dilute sulphuric acid and deutoxide of manganese, is decomposed, the chlorine is extricated, and the sodium and deutoxide of manganese, having been converted, by a transfer of oxygen from the latter to the former, into soda and protoxide, unite with the sulphuric acid, and form sulphate of soda and sulphate of protoxide of manganese, which remain behind. The water, intended to receive the gas is most conveniently placed in a Wolfe's bottle, connected with a common bottle containing milk of lime, to absorb any excess of chlorine, which might otherwise produce inconvenience by its escape.

The Edinburgh process differs from the Dublin in forming the solution in the liquid way, avoiding the transmission of the gas from one vessel to another. Red oxide of lead is substituted for the deutoxide of manganese, and performs the same part in the play of affinities. It oxidizes the sodium, and is itself reduced to the state of protoxide. The chlorine is set free and dissolved by the water, and the sulphuric acid forms with the soda, sulphate of soda which remains in solution, and with the protoxide, sulphate of protoxide of lead which is precipitated. The action is completed in the course of a few hours, and the sulphate of lead having subsided, the supernatant liquid forms an aqueous solution of chlorine, containing a little sulphate of soda.

Properties. The Dublin chlorine water has a pale yellowish-green colour, an astringent taste, and the peculiar odour of the gas. Like gaseous chlorine, it destroys vegetable colours. When cooled to about the freezing point, it forms deep-yellow crystalline plates, consisting of hydrate of chlorine. At the temperature of 50° , it contains about twice its volume of the gas. It is decomposed by light, with the production of muriatic acid, and the evolution of oxygen, and hence must be kept in a dark place. The Edinburgh preparation differs from the Dublin only in containing a small portion of sulphate of soda, which is not thought to interfere with its medicinal properties.

Chlorine is an elementary gaseous fluid, of a greenish-yellow colour, and characteristic and disagreeable smell and taste. It is a supporter of combustion. Its sp. gr. is 2.47, and equivalent number 35.42. It is irrespirable when undiluted. When the attempt is made to breathe it, even much diluted, it excites cough and a sense of suffocation, and causes a discharge from the nostrils resembling coryza. When breathed in considerable quantities, it produces spitting of blood, violent pains, and sometimes death. It has been recommended in minute doses, by Gannal, in chronic bronchitis and pulmonary consumption, exhibited by inhalation four or six times a day. Its first effect is to produce some dryness of the fauces, with increased expectoration for a time, followed ultimately with diminution of the sputa, and amendment. Dr. Christison states that he has repeatedly observed these results in chronic catarrh; and in consumption, both he and Dr. Elliotson have witnessed the temporary melioration of the symptoms from chlorine inhalations, such as they have never obtained by any other means. The liquid in the inhaler may be formed of water containing from ten to thirty drops of chlorine water, or of chlorinated lime dissolved in forty parts of water, to which a drop or two of sulphuric acid must be added each time the inhalation is practised; the inhaler being placed in water, heated to about 100° . For a notice of *iodine inhalations*, see page 396.

Medical Properties and Uses. Chlorine water is stimulant and antiseptic. It has been used in typhus, and chronic affections of the liver; but the diseases in which it has been most extolled are scarlatina and malignant sorethroat. Externally it may be used, duly diluted, as a gargle in putrid sorethroat, as a wash for ill-conditioned ulcers and cancerous sores, and as a local bath in diseases of the liver; though for the latter purpose, the nitromuriatic acid, which is in effect a solution of chlorine, is usually employed. As it depends upon chlorine for its activity, its medical properties coincide generally with those of chlorinated lime, chlorinated soda, and nitromuriatic acid, under which heads they are more particularly given. (See *Calx Chlorinata*, *Liquor Sodæ Chlorinatæ*, and *Acidum Nitromuriaticum*.)

The dose of chlorine water is from one to four fluidrachms, properly diluted.

B.

AQUA CINNAMOMI. *U. S., Lond., Ed., Dub. Cinnamon Water.*

"Take of Oil of Cinnamon *half a fluidrachm*; Carbonate of Magnesia *half a drachm*; Distilled Water *two pints*. Rub the Oil of Cinnamon first with the Carbonate of Magnesia, then with the Water gradually added, and filter through paper." *U. S.*

"Take of Cinnamon, bruised, *a pound and a half*, or Oil of Cinnamon *two drachms*; Proof Spirit *seven fluidounces*; Water *two gallons* [Imperial measure]. Distil a gallon." *Lond.*

The *Dublin College* takes *a pound* of cinnamon bruised and macerated for a day in water, or *three drachms* of the oil, and, with sufficient water to prevent empyreuma, distils a gallon. The *Edinburgh College* prepares this from cinnamon in the same manner as the Water of Cassia.

Of these processes, that of the United States Pharmacopœia is decidedly preferable, as much easier than the others, and affording a product in every respect equal, if not superior. Cinnamon water is a favourite vehicle with many practitioners for other less pleasant medicines; but should be used cautiously in inflammatory affections. For ordinary purposes it is sufficiently strong when diluted with an equal measure of water.

Off. Prep. Mistura Cretæ, *U. S., Lond.*; Mistura Guaiaci, *Lond., Ed.*; Mistura Spiritus Vinj Gallici, *Lond.*

W.

AQUA FLORUM AURANTII. *Lond. AURANTII AQUA.* *Ed. Orange Flower Water.*

"Take of Orange Flowers *ten pounds*; Proof Spirit *seven fluidounces*; Water *two gallons* [Imperial measure]. Distil a gallon." *Lond.*

This is placed by the *Edinburgh College* in their *Materia Medica* list, with the following explanation;—"Distilled water of the flowers of *Citrus vulgaris*, and sometimes of *Citrus Aurantium*."

Orange-flower water is not prepared in this part of the United States, though the flowers might be imported for the purpose, if previously incorporated with one-third or one-quarter of their weight of common salt. It is made in Italy and France, and the flowers of the bitter orange are preferred, as yielding the most fragrant product. It is nearly colourless, though usually of a pale yellowish tint. In consequence of being kept in copper bottles, it is apt to contain metallic impurity. This is chiefly carbonate of lead, derived from the lead used as a solder to join the sheets of copper. The *Edinburgh College*, therefore, directs that it should not be affected by sulphuretted hydrogen, which, if either lead or copper were present, would throw down a dark precipitate. Much colour, an offensive odour, or mouldiness, would indicate impurity derived from the flowers in the process of distillation. Orange-flower water is used exclusively as a perfume. W.

AQUA FŒNICULI. *U. S., Lond., Ed., Dub. Fennel Water.*

The *U. S. Pharmacopœia* directs this to be prepared from Oil of Fennel, in the same manner as cinnamon water. (See *Aqua Cinnamomi*.)

The *London* and *Edinburgh Colleges* prepare it in the same manner as dill water (see *Aqua Anethi*); the *Dublin College*, in the same manner as caraway water (see *Aqua Carui*).

Fennel water is an agreeable vehicle for other medicines, and useful when a mild aromatic is indicated.

W.

AQUA LAURO-CERASI. *Ed., Dub. Cherry-laurel Water.*

“Take of Fresh Leaves of Cherry-laurel, *a pound*; Water *two pints and a half* [Imperial measure]; Compound Spirit of Lavender *an ounce*. Chop down the Leaves, mix them with the Water, distil off one pint [Imp. meas.], agitate the distilled liquid well, filter it if any milkiness remain after a few seconds of rest, and then add the Lavender spirit.” *Ed.*

“Take of Fresh Leaves of Cherry Laurel *a pound*; Water *three pints*. Distil a pint, and instead of Rectified Spirit, add of Compound Spirit of Lavender *an ounce*.” *Dub.*

The substitution of the compound spirit of lavender for alcohol, is in order to impart colour to the preparation, and thus prevent it from being mistaken for common water. It is employed in Europe as a sedative narcotic, identical in its properties with a dilute solution of hydrocyanic acid; but is of very uncertain strength. The dose is from thirty minims to a fluidrachm. *W.*

AQUA MENTHÆ PIPERITÆ. *U.S., Lond., Ed., Dub. Peppermint Water.*

This is prepared, according to the United States Pharmacopœia, from the oil of peppermint, in the manner directed for cinnamon water. (See *Aqua Cinnamomi*.)

“Take of Peppermint, dried, *two pounds*, or Oil of Peppermint, *two drachms*; Proof Spirit *seven fluidounces*; Water *two gallons* [Imperial measure]. Distil *a gallon*. When the fresh herb is used the quantity should be doubled.” *Lond.*

The *Edinburgh College* mixes *four pounds* of fresh or *two* of dry peppermint, *two gallons* [Imp. meas.] of water, and *three fluidounces* of rectified spirit, and distils a gallon. The *Dublin College* proceeds as in the instance of Caraway Water, employing *a pound and a half* of the herb; or simply distils a mixture of *three drachms* of the oil and *a gallon* of water. *W.*

AQUA MENTHÆ PULEGII. *Lond. AQUA PULEGII. Ed., Dub. Pennyroyal Water.*

This is prepared from the European pennyroyal or its oil, precisely in the manner directed by the British Colleges for peppermint water. It is not used in this country, as we have not the plant. A water prepared from the *Hedeoma pulegioides*, or American pennyroyal, might be substituted.

Pennyroyal water is employed for the same purposes as those of peppermint and spearmint.

Off. Prep. Mistura Ammoniaci, *Dub.*; Mistura Assafœtidæ, *Dub.* *W.*

AQUA MENTHÆ VIRIDIS. *U.S., Lond., Ed., Dub. Spearmint Water.*

This is prepared, according to the United States Pharmacopœia, from the oil of spearmint, in the manner directed for cinnamon water. (See *Aqua Cinnamomi*.)

By the British Colleges it is prepared in the manner directed by them for peppermint water.

The two mint waters are among the most grateful and most employed of this class of preparations. Together with cinnamon water, they are used in this country, almost to the exclusion of all others, as the vehicle of medicines given in the form of mixture. They serve not only to conceal or qualify the taste of other medicines, but also to counteract their nauseating properties. The peppermint water is generally thought to have a more pleasant flavour than that of spearmint, but some prefer the latter. Their effects are the same. *W.*

AQUA PICIS LIQUIDÆ. *Dub. Tar Water.*

"Take of Tar *two pints*; Water *a gallon*. Mix, stirring with a wooden rod for fifteen minutes; then, after the Tar shall have subsided, strain the liquor, and keep it in well stopped bottles." *Dub.*

Water takes from tar a small portion of acetic acid, empyreumatic oil, and resinous matter, acquiring a sharp empyreumatic taste, and the colour of Madeira wine. Thus impregnated it is stimulant and diuretic; and, though at present little used, was formerly highly extolled as a remedy in pulmonary consumption. It may be given with occasional advantage in chronic catarrhal affections, and complaints of the urinary passages. From one to two pints may be taken in the course of the day. It is also used as a wash in chronic cutaneous affections.

W.

AQUA PIMENTÆ. *Lond., Ed., Dub. Pimento Water.*

"Take of Pimento, bruised, *a pound*, or Oil of Pimento *two drachms*; Proof Spirit *seven fluidounces*; Water *two gallons* [Imperial measure]. Distil a gallon." *Lond.*

The *Edinburgh College* mixes *a pound* of bruised pimento, *two gallons* [Imp. meas.] of water, and *three fluidounces* of rectified spirit, and distils a gallon. The *Dublin College* distils a gallon from *half a pound* of pimento, previously bruised, and macerated for twenty-four hours in *a pint* of water, and takes care that sufficient water shall remain to prevent empyreuma.

Pimento water is brownish when first distilled, and upon standing deposits a brown resinous sediment. It is used as a carminative in the dose of one or two fluidounces.

W.

AQUA ROSÆ. *U.S., Lond., Ed., Dub. Rose Water.*

"Take of Fresh Hundred-leaved Roses *eight pounds*; Water *two gallons*. Mix them and distil a gallon." *U.S.*

The *Dublin College* orders a gallon of the water to be distilled from *eight pounds* of the petals. The *London College* takes *ten pounds* of roses, *seven fluidounces* of proof spirit, and *two gallons* [Imperial measure] of water, and distils a gallon. The *Edinburgh College* proceeds as the *London*, substituting *three fluidounces* of rectified spirit for seven of proof spirit; and adds the following notice. "The petals should be preferred when fresh; but it also answers well to use those which have been preserved by beating them with twice their weight of muriate of soda."

It should be observed that, in the nomenclature of the United States Pharmacopœia, the term "Roses" implies only the petals of the flower. These are directed in the recent state; but it is said that when preserved by being incorporated with one-third of their weight of common salt, they retain their odour, and afford a water equally fragrant with that prepared from the fresh flower. Rose water is sometimes made by distilling together water and the oil of roses.

When properly prepared, it has the delightful perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters it is liable to spoil when kept; and the alcohol which is added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour by promoting the acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. This distilled water is chiefly employed on account of its pleasant odour in collyria and other lotions. It is wholly destitute of irritating properties, unless when it contains alcohol.

Off. Prep. Confectio Rosæ, *U.S.*; Mistura Ferri Composita, *U.S.*, *Lond., Ed., Dub.*; Mist. Moschi, *Lond.*; Ung. Aquæ Rosæ, *U.S.* W.

AQUA SAMBUCI. *Lond., Ed. Elder Water.*

"Take of Elder Flowers *ten pounds*, or of Oil of Elder *two drachms*; Proof Spirit *seven fluidounces*; Water *two gallons* [Imperial measure]. Distil a gallon." *Lond.*

The *Edinburgh College* mixes *ten pounds* of the fresh flowers, *two gallons* [Imp. meas.] of water, and *three fluidounces* of rectified spirit, and distils a gallon.

Elder flowers yield very little oil upon distillation; and if the water be needed, it may be best prepared from the flowers. In this country it is not used. W.

ARGENTUM.

Preparations of Silver.

ARGENTI CYANURETUM. *U. S.* ARGENTI CYANIDUM. *Lond.* *Cyanuret of Silver. Cyanide of Silver.*

"Take of Nitrate of Silver *fifteen drachms*; Hydrocyanic Acid, Distilled Water, each, *a pint*. Having dissolved the Nitrate of Silver in the Water, add the Hydrocyanic Acid and mix them. Wash the precipitate with Distilled Water and dry it." *U. S.*

The *London* formula is the same as that above given, which was adopted from the *London Pharmacopœia*, merely adjusting the proportions to suit the *U. S.* official measure, instead of the Imperial measure.

This preparation was introduced into the *London Pharmacopœia*, and afterwards into that of the United States, for the purpose of being used in the extemporaneous preparation of diluted hydrocyanic acid. (See page 786.) Its formation is a case of double decomposition between the oxide of silver of the nitrate, and the hydrocyanic acid, resulting in the formation of water, and a white curdy precipitate of cyanuret or cyanide of silver.

Properties. Cyanuret of silver is a tasteless white powder, insoluble in water and cold nitric acid, but readily soluble, with decomposition, in that acid when boiling hot. It is decomposed by muriatic and hydrosulphuric acid, and the hydrosulphates. It is not soluble in potassa or soda, but readily so in ammonia. When well dried, it is resolved by a red heat into silver and cyanogen gas; but when it contains water, it yields hydrocyanic acid and cyanogen, the residue being silver mixed with charcoal. It consists of one eq. of cyanogen 26.39, and one of silver 108 = 134.39. It has no medical uses.

Off. Prep. Acidum Hydrocyanicum, *U. S., Lond.*

B.

ARGENTI NITRAS. *U. S., Lond., Ed.* ARGENTI NITRAS FUSUM. *Dub.* *Nitrate of Silver. Lunar Caustic.*

"Take of Silver, in small pieces, *an ounce*; Nitric Acid *five fluidrachms*; Distilled Water *two fluidounces*. Mix the Acid with the Water, and dissolve the Silver in the mixture on a sand-bath; then gradually increase the heat, so that the resulting salt may be dried. Melt this in a crucible over a gentle fire, and continue the heat until ebullition ceases; then immediately pour it into suitable moulds." *U. S.*

"Take of Silver *an ounce and a half*; Nitric Acid *a fluidounce* [Imperial measure]; Distilled Water *two fluidounces* [Imp. meas.]. Mix the Nitric Acid with the Water, and dissolve the Silver in them on a sand-bath. Then increase the heat gradually that the Nitrate of Silver may be dried. Melt this in a crucible with a slow fire, until, the water being expelled, ebullition has ceased; then immediately pour it into proper moulds." *Lond.*

“Take of pure Silver *an ounce and a half*; Pure Nitric Acid *a fluid-ounce* [Imperial measure]; Distilled Water *two fluidounces* [Imp. meas.]. Mix the Acid and Water, add the Silver, and dissolve it with the aid of a gentle heat; increase the heat gradually till a dry salt be obtained; fuse the salt in an earthenware or porcelain crucible, and pour the fused matter into iron moulds, previously heated and greased slightly with tallow. Preserve the product in glass vessels.” *Ed.*

“Dissolve Silver in Diluted Nitric Acid [in the manner directed in the formula for *Crystals of Nitrate of Silver*]; then evaporate the solution to dryness. Melt the residuum, placed in a crucible, over a slow fire; then pour it out into proper moulds, and keep it in a glass bottle.” *Dub.*

During the solution of silver in nitric acid, part of the acid is decomposed into nitric oxide which is given off and becomes red fumes by contact with the atmosphere, and oxygen which oxidizes the silver. The oxide formed then combines with the remainder of the acid, and generates the nitrate of silver in solution. The water is next driven off by heat, and the salt fused and cast into little cylinders about the size of a quill. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both muriatic and sulphuric acids, should never be used in this process. The muriatic acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble sulphate of silver. In the former London and Edinburgh Pharmacopœias the nitric acid was used in excess; but was reduced to the proper proportion upon the revision of those works in 1836 and 1839. As the salt sinks into a common crucible, the fusion should be performed in one of porcelain, as recommended by the Edinburgh College, the size of which should be sufficient to hold five or six times the quantity of the dry salt operated on, in order to prevent its overflowing in consequence of the ebullition. Sometimes small portions of the liquid are spirted out; and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should be warmed, but not greased, as directed by the Edinburgh College; as grease furnishes organic matter which partially decomposes the salt.

Properties. Nitrate of silver is a white salt, having an intensely metallic, bitter taste. As prepared by the above process, it is in the form of hard, brittle sticks, at first white, but becoming gray and more or less dark under the influence of light, owing to the reduction of the silver, effected probably by organic matter or sulphuretted hydrogen contained in the atmosphere. That the change does not depend on the sole action of light has been proved by Mr. Scanlan, who finds that nitrate of silver, in a clean glass tube hermetically sealed, undergoes no change by exposure to light; while on the other hand it is known that the solution of nitrate of silver is discoloured by the most minute portion of organic matter, of which it is a delicate test. Its affinity for animal matter is evinced by its forming definite compounds with albumen and fibrin. The surface of the sticks often becomes dark coloured and nearly black, and when they are broken across, they exhibit a crystalline fracture with a radiated surface. Nitrate of silver is soluble in its own weight of cold water, and in four parts of alcohol. When perfectly pure it is wholly soluble in distilled water; but even good samples of the fused salt will not totally dissolve, a very scanty black powder being left of

reduced silver, arising from the salt having been exposed to too high a heat in fusion. Its solution stains the skin of an indelible black colour. When exposed to heat it fuses at 426° , and at about 600° undergoes decomposition, with evolution of oxygen and nitrous acid, and reduction of the metal. This statement explains why it is necessary to guard against the application of too high a heat during the fusion of the salt. Nitrate of silver is incompatible with almost all spring and river water, on account of the common salt usually contained in it; with soluble chlorides; with sulphuric, hydrosulphuric, muriatic, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime-water; and with astringent vegetable infusions. It is an anhydrous salt, and consists of one eq. of nitric acid 54.15, and one of oxide of silver $116=170.15$.

Impurities and Tests. Nitrate of silver is liable to contain free silver from having been exposed to too high a heat, the nitrates of lead and copper from the impurity of the silver dissolved in the acid, and nitrate of potassa from fraudulent admixture. Free silver will be left undissolved as a black powder, after the action of distilled water. A very slight residue of this kind is hardly avoidable; but if there is much free silver, it will be shown by the surface of a fresh fracture of one of the sticks presenting an unusually dark-gray colour. (*Christison.*) A solution of chloride of sodium in excess should throw down the whole of the silver as a white curdy precipitate, and nothing besides. This precipitate should be entirely soluble in ammonia. If not entirely soluble, the insoluble part is probably chloride of lead. If the supernatant liquid, after the removal of the above mentioned precipitate, be discoloured or precipitated by sulphuretted hydrogen, the fact shows the presence of metallic matter, which is probably copper or some remains of lead, or both. In order to detect nitre, a solution of the suspected salt should be precipitated by muriatic acid in excess and sulphuretted hydrogen, to remove the silver, and other metals if they happen to be present. The filtered solution, if the salt be pure, will entirely evaporate by heat; if it contain nitre, this will be left, easily recognizable by its properties as a nitrate. This impurity sometimes exists in nitrate of silver in large amount, varying, according to different statements, from 10 to 75 per cent. According to Dr. Christison, it may be suspected if the sticks present a colourless fracture. A test is given in the Edinburgh Pharmacopœia for indicating impurity in nitrate of silver, without determining its nature. It depends upon the fact that the pure salt requires for its conversion into chloride, a given quantity of a muriate or chloride; and that if a little less than this quantity be used to precipitate it, the supernatant liquid will be precipitable by more of the test. Now this will not be the case with the impure salt, unless its impurity be minute. In applying this test, the Edinburgh College directs that 29 grains of the salt should be dissolved in a fluidounce of distilled water acidulated with nitric acid, precipitated with a solution of 9 grains of muriate of ammonia, briskly agitated for a few seconds, and then allowed to rest. If the salt be impure, it will not be precipitated on the addition of more of the test.

Medical Properties and Uses. Nitrate of silver, as an internal remedy, is deemed tonic and antispasmodic. The principal diseases in which it has been employed are epilepsy, chorea, angina pectoris, and other spasmodic affections. In epilepsy it occasionally effects a cure; but the kind of cases to which it is applicable and its *modus operandi* are not understood. It is said to produce most good in this disease when it acts upon the bowels. Dr. James Johnson and other practitioners have found it useful as a palliative and sedative in chronic disease of the stomach attended with pain and vomiting. Dr. Boudin, of Marseilles, has employed it in typhoid fever as

a remedy for the inflammation and ulceration of the ileum, which constitute the most constant lesion in that disease. When the gastric symptoms predominate, he gives the nitrate in pill, in doses of a fourth to half a grain. When diarrhœa is the principal symptom, he administers, night and morning by injection, a solution of the salt containing three or four grains to six fluidounces of water. The injections appeared to be useful by promoting the cicatrization of the intestinal ulcers, and were found to extend their operation as high up as the small intestines. In chronic diarrhœa, especially in that kind attendant on phthisis, Dr. Macgreggor, of Dublin, has found the nitrate of silver, conjoined with opium, a valuable remedy. Whatever may be the remedial value of this salt internally administered, its occasional effect of producing a blue or black discoloration of the skin, which can hardly be removed, is a great objection to its use. This effect proves the absorption of the medicine, and is alleged to show itself first on the tongue and fauces. The discoloration is said to be removed by a steady course of cream of tartar. Dr. A. T. Thomson has suggested as a preventive of this effect, the administration of nitric acid in conjunction with the salt; and Dr. Patterson, of Ireland, has proposed as a substitute for the nitrate, the iodide of silver, which he supposes would have the same remedial effect, without producing discoloration.

Externally nitrate of silver is employed as a vesicant, stimulant, and escharotic, either dissolved in water, or in the solid state. In the proportion of about half a grain to the fluidounce of water, it has been recommended as a mouth wash for healing ulcers produced by mercury. Dissolved to the extent of from one to five grains in the same quantity of water, it is used for the purpose of stimulating indolent ulcers, and as an injection for fistulous sores. A solution containing two grains to the fluidounce is an excellent application in ophthalmia with ulcers of the cornea, in fetid discharges from the ear, in aphthous affections of the mouth, and spongy gums. It is, in general, most conveniently applied to ulcers by means of a camel's hair pencil. A drachm of the salt, dissolved in a fluidounce of water, forms an escharotic solution, which may often be resorted to with advantage. But nitrate of silver is most frequently employed in the solid state; and as it is not deliquescent nor apt to spread, it forms the most manageable caustic that can be used. When thus employed, it is useful to coat the caustic, as recommended by M. Dumeril, by dipping it into melted engraver's sealing wax, which strengthens the stick, protects it from change, prevents it from staining the fingers, and affords facilities for limiting the action of the caustic to particular spots. If it is desired, for example, to touch a part of the throat with the caustic, it is prepared by scraping off the wax, with a penknife, to a suitable extent from one end. If the solid nitrate be applied three or four times to the moistened skin, it generally vesicates, causing usually less pain than is produced by cantharides. It is employed in the solid form to destroy strictures of the urethra, warts and excrescences, fungous flesh, incipient chancres, and the surface of other ulcers. Mr. Higginbottom considers its free application to ulcers, so as to cover them with an eschar, as an excellent means of expediting their cicatrization. He alleges that, if an adherent eschar be formed, the parts underneath heal before it falls off. The same writer recommends lunar caustic as a topical remedy in various external inflammations, but particularly in erysipelas, applied both to the inflamed and to surrounding healthy parts. In some cases it is sufficient to blacken the cuticle; in others it is best to produce vesication. It has also been used with good effect, in the solid state, by Dr. Jewell in leucorrhœa, and by

Ricord, Hannay, and others in the gonorrhœa of women. In these cases the pain produced is much less than would be expected. It has been recommended in gonorrhœa in the male, even in the acute stage, used in solution containing 10 or 12 grains to the fluidounce; but, although some quick cures are well authenticated, the practice is extremely dangerous. In smallpox it has been proposed by Bretonneau and Serres, to cauterize each pustule after its top has been removed, on the first or second day of the eruption, in order to arrest its development and prevent pitting. The solid nitrate also forms an efficacious application to certain ulcerations in the throat, to punctured and poisoned wounds, and to chilblains, slowly rubbed over the moistened part. If, unexpectedly, the pain produced by the external use of the nitrate should be excessive, it may be immediately allayed by washing the parts with a solution of common salt, which acts by decomposing the caustic.

The dose of nitrate of silver is a fourth of a grain, gradually increased to four or five grains, three times a day. It should always be given in pill, in which form, according to Dr. Powell, the system bears a dose three times as large as when given in solution. In the treatment of epilepsy, this physician recommends the exhibition at first of grain doses, to be gradually increased to six grains, three times a day. Its effects vary very much, owing no doubt to the salt being more or less decomposed by the substances used in preparing it in pill, or with which it comes in contact in the stomach. It should not be made up into pill with crumb of bread, as this contains common salt, but with some vegetable powder and mucilage. Considering that chloride of sodium is used in food, and exists in the secretions, and that free muriatic acid and albuminous fluids are present in the stomach, it is almost certain that, sooner or later, the whole of the nitrate of silver will be converted into a chloride or albuminate, far less active than the original salt. Such being the inevitable result when the nitrate is given, the question arises how far it would be expedient to anticipate the change, and give the silver as a chloride ready formed. One of the authors of this work has tried the chloride in large doses, in two very unpromising cases of epilepsy, but without advantage. The *oxide of silver*, to be noticed in the Appendix, would probably produce the remedial effects of this metal, and is not liable to the objections which lie to the nitrate and chloride; to the former on account of its unequal activity, to the latter as being extremely insoluble, and difficultly decomposable. As the fused nitrate is often impure, it is safer to employ the crystallized salt for internal exhibition. (See *Argenti Nitratis Crystalli*.) Solutions intended for the eye should be made with distilled water; for ordinary purposes, good common water is sufficiently pure for dissolving the salt.

Nitrate of silver, in an over-dose, produces the effects of the corrosive poisons. The proper antidote is common salt, which acts by converting the poison into the insoluble chloride of silver. Consecutive inflammation must be combated by bleeding, both general and local, and other antiphlogistic measures.

Off. Prep. Argenti Cyanuretum, U. S., Lond.; Liquor Argenti Nitratis, Lond. B.

LIQUOR ARGENTI NITRATIS. Lond. *Solution of Nitrate of Silver.*

“Take of Nitrate of Silver *a drachm*; Distilled Water *a fluidounce* [Imperial measure]. Dissolve the Nitrate of Silver in the Water, and strain;

then, the access of light being prevented, keep it in a well-closed vessel.”
Lond.

The London College have made the above solution officinal in their Pharmacopœia of 1836. According to Mr. Phillips, it is intended merely as a test for detecting the presence of muriatic acid and soluble chlorides, with which it gives a white curdy precipitate, insoluble in acids and the fixed alkalies, but readily soluble in ammonia. This solution, however useful as a test, is certainly out of place in a Pharmacopœia. B.

ARGENTI NITRATIS CRYSTALLI. *Dub.* *Crystals of Nitrate of Silver.*

“Take of Silver, laminated and cut in pieces, *thirty-seven parts*; Diluted Nitric Acid *sixty parts*. Put the Silver in a glass vessel, and pour upon it the Acid, previously diluted with water. Dissolve the metal with a heat gradually increased, and, by evaporation and refrigeration, let crystals be formed. Dry them without heat, and preserve them in a glass bottle in a dark place.” *Dub.*

The Dublin is the only Pharmacopœia noticed in this work which has made the crystals of nitrate of silver officinal; and the motive for doing so is to have a purer salt for internal exhibition than the fused nitrate generally is. By an oversight in the process, the acid, though ordered to be the officinal diluted acid, is directed to be diluted in the body of the formula. The crystals are in colourless transparent rhomboidal plates, often of large size. Their other properties, as well as their medical applications, are the same as those of the fused nitrate; to the article on which the reader is referred. B.

ARSENICUM.

Preparations of Arsenic.

ARSENICI OXYDUM ALBUM SUBLIMATUM. *Dub.* *Sublimed White Oxide of Arsenic.*

“Reduce the Oxide of Arsenic to a coarse powder, and, avoiding the vapours, expose it to heat in a suitable vessel, that the White Oxide of Arsenic may sublime.” *Dub.*

The Dublin College, deeming the commercial white oxide of arsenic (*Acidum Arseniosum*, U.S., *Lond.*) not sufficiently pure for medicinal employment, has given the above formula for its purification. But as the commercial oxide itself has undergone a second sublimation, this process is superfluous. The only precaution necessary to be taken on the part of the apothecary, is to purchase the oxide in lump; for when in powder it is apt to be adulterated with chalk or sulphate of lime. The chemical, medical, and toxicological properties of this substance have been given under the head of *Acidum Arseniosum*.

Off. Prep. Liquor Arsenicalis, *Dub.*

B.

LIQUOR POTASSÆ ARSENITIS. *U.S., Lond.* LIQUOR ARSENICALIS. *Ed., Dub.* *Solution of Arsenite of Potassa. Arsenical Solution. Fowler's Solution.*

“Take of Arsenious Acid, in small fragments, Pure Carbonate of Potassa, each, *sixty-four grains*; Distilled Water *a sufficient quantity*; Compound Spirit of Lavender *half a fluidounce*. Boil the Arsenious Acid and Carbonate of Potassa with twelve fluidounces of Distilled Water, in a glass vessel, till the Acid is entirely dissolved. To the solution, when cold, add

the Spirit of Lavender, and afterwards sufficient Distilled Water to make it fill exactly the measure of a pint." *U. S.*

"Take of Arsenious Acid, broken into small pieces, Carbonate of Potassa, each, *eighty grains*; Compound Tincture of Lavender *five fluidrachms*; Distilled Water *a pint* [Imperial measure]. Boil the Arsenious Acid and Carbonate of Potassa with half a pint of the Water in a glass vessel, until they are dissolved. Add the Compound Tincture of Lavender to the cooled liquor. Lastly, add besides sufficient Distilled Water, that it may accurately fill a pint measure." *Lond.*

The *Edinburgh* formula is substantially the same with the London, from which it injudiciously varies by ordering the arsenious acid in powder, and water instead of distilled water. In it the lavender preparation is misnamed "tincture," it being recognised as a spirit in the nomenclature of the Edinburgh College.

The *Dublin* is the same as the *U. S.* formula, with the exception that the sublimed white oxide of arsenic of the College is used instead of the commercial oxide, and that the quantity of the arsenious acid and carbonate is reduced from sixty-four to sixty grains.

This preparation originated with Dr. Fowler, and was intended as a substitute for the celebrated empirical remedy known under the name of "the tasteless ague drop." It is an arsenite of potassa dissolved in water, and is formed by the combination of the arsenious acid with the potassa of the carbonate, the carbonic acid being evolved. The name, therefore, by which it is designated in the United States and London Pharmacopœias, is obviously the most correct. The spirit of lavender is added to give it taste, in order to prevent its being mistaken for simple water. The United States preparation is of about the same strength as those of the London and Edinburgh Colleges; for, although one-fourth more acid and alkali is taken in the London and Edinburgh than in the *U. S.* formula, yet it is to be recollected that the Imperial pint is nearly one-fourth larger than the wine pint. The Dublin solution is one-sixteenth weaker, in consequence of the very injudicious alteration from the standard formula, of substituting sixty instead of sixty-four grains of arsenious acid to the pint of liquid. Dr. Barker, in his Observations on the Dublin Pharmacopœia, informs us, that the reason for this change was the supposition that less danger of error would arise in weighing out sixty than sixty-four grains; as the former quantity could be weighed by a single weight.

In making this preparation, care should be taken that the arsenious acid be pure. This object is best secured by using the acid in small fragments, instead of in powder. Sulphate of lime is a common adulteration, and if present will remain undissolved, and cause the solution to be weaker than it should be. Hence if the arsenious acid do not entirely dissolve, the preparation must be rejected.

Properties. Solution of arsenite of potassa is a transparent liquid, having the colour, taste, and smell of the spirit of lavender. It has a strong alkaline reaction. It is decomposed by the usual reagents of arsenic, such as nitrate of silver, the salts of copper, lime-water, and sulphuretted hydrogen; and is incompatible with infusions and decoctions of cinchona. Before sulphuretted hydrogen will act, the solution must be supersaturated with some acid, as the muriatic or acetic.

Medical Properties and Uses. This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arsenious Acid*. Its liquid form makes it convenient for exhibition and gradual increase; and it is the preparation generally resorted to,

when arsenic is given internally. It is employed principally in intermittent fever. Dr. Thomas D. Mitchell, Professor of Materia Medica in the University of Transylvania, has given the result of his experience, as to its efficacy and safety in this disease, when exhibited in the large dose of fifteen or twenty drops three times a day. (*Med. Recorder*, iv. 640.) It is a valuable resource in the intermittents of children, who are with difficulty induced to swallow bark or even sulphate of quinia. Dr. Dewees (*Phil. Journ. of Med. and Phys. Sci.* xiv. 187.) relates the case of a child only six weeks old, affected with a severe tertian, in which this solution was given with success. A fluidrachm was diluted with twelve fluidrachms of water; and of this six drops were given every four hours.

Fowler's solution, while partaking of the general therapeutical properties of the arsenical preparations, appears to be peculiarly adapted to the treatment of several diseases. It has been employed with encouraging success in lepra and other inveterate cutaneous affections. The late Dr. S. Colhoun (*Med. Recorder*, iii. 347.) published an account of five cases of nodes, successfully treated by it; and in consequence of his success, Dr. Baer of Baltimore, and the late Dr. Eberle, were induced to give it a trial in this affection, and they obtained satisfactory results. Several cases of chorea, cured by this remedy, are reported by Mr. Martin, Mr. Slater, and Dr. Gregory, in the *Medico-Chirurgical Transactions of London*. Two interesting cures of periodical headache, performed by this solution, are related by Dr. Otto of Philadelphia, in the fourth and fifth volumes of the *North American Med. and Surg. Journal*. Mr. H. Hunt found it useful in menorrhagia, but prefers the use of arsenious acid, as less apt to produce unpleasant effects, requiring the discontinuance of the remedy. (See page 19.) A diluted solution, in the proportion of a fluidrachm to the fluidounce of water, has been used with advantage as a topical application to foul ulcers, occasioned by the indiscreet use of mercury.

Each fluidrachm of the solution contains half a grain of arsenious acid. The average dose for an adult is ten drops two or three times a day. For the peculiar effects which it produces in common with the other arsenical preparations, and for the signs by which the practitioner is warned that its further exhibition would be unsafe, the reader is referred to the article on *Arsenious Acid*. B.

BARYTA.

Preparations of Baryta.

BARI CHLORIDUM. *U. S., Lond.* BARYTÆ MURIAS. *Ed., Dub.*
Chloride of Barium. Muriate of Baryta.

"Take of Carbonate of Baryta, in small fragments, *a pound*; Muriatic Acid *twelve fluidounces*; Water *three pints*. Mix the Acid with the Water, and gradually add the Carbonate of Baryta. Towards the close of the effervescence apply a gentle heat, and, when the action has ceased, filter the liquor, and boil it down so that crystals may form when it cools." *U. S.*

"Take of Carbonate of Baryta, broken into small pieces, *ten ounces*; Hydrochloric [Muriatic] Acid *half a pint* [Imperial measure]; Distilled Water *two pints* [Imp. meas.]. Mix the Acid with the Water, and add the Carbonate of Baryta gradually to them. Then, heat being applied, and the effervescence finished, strain, and boil down the liquor that crystals may form." *Lond.*

The *Edinburgh College* gives two processes for obtaining this chloride;

one in which the native carbonate of baryta is used, the other in which the native sulphate is employed. The process with the carbonate is the same with the London, just quoted; the formula with the sulphate is as follows.

“Take of Sulphate of Baryta *two pounds*; Charcoal, in fine powder, *four ounces*; Pure Muriatic Acid *a sufficiency*. Heat the sulphate to redness, reduce it to fine powder, mix the charcoal with it thoroughly, heat the mixture in a covered crucible for three hours at a low white heat. Pulverize the product, put it gradually into five pints [Imperial measure] of boiling water; boil for a few minutes; let it rest for a little over a vapour-bath; pour off the clear liquor, and filter it if necessary, keeping it hot. Pour three pints [Imp. meas.] of boiling water over the residuum, and proceed as before. Unite the two liquids; and while they are still hot, or, if cooled, after heating them again, add Pure Muriatic Acid gradually so long as effervescence is occasioned. In this process the solutions ought to be as little exposed to the air as possible; and in the last step the disengaged gas should be discharged by a proper tube into a chimney or the ash-pit of a furnace. Strain the liquor, concentrate it, and set it aside to crystallize.” *Ed.*

The *Dublin College* obtains the chloride of barium by means of the native sulphate also; but as the process is in principle the same as that just quoted from the *Edinburgh Pharmacopœia*, it need not be given.

When the carbonate of baryta is employed for obtaining chloride of barium, the reactions are exceedingly simple. The muriatic acid displaces the carbonic acid with effervescence; and by reacting with the baryta, forms chloride of barium and water. A solution of chloride of barium being thus obtained, it yields crystals of the chloride by concentration and cooling. The reactions occurring in the process in which the sulphate is used, are more complicated. The ignition with carbonaceous matter deoxidizes its constituents, converting it into sulphuret of barium, the oxygen flying off in combination with the carbon as carbonic oxide and acid. The sulphuret of barium, when dissolved in water, is decomposed on the addition of muriatic acid, sulphuretted hydrogen being given off in large quantities, and chloride of barium formed in solution, from which, in the usual manner, the solid salt is obtained. The direction to discharge the sulphuretted hydrogen into a chimney or the ash-pit of a furnace, is intended to provide for its decomposition by smoke; for if the gas is not disposed of in this or some similar way, it becomes exceedingly annoying to the operator.

Of the official processes, that in which the native carbonate is used is the simplest and most convenient; but as it may happen that the operator possesses the native sulphate and not the carbonate, the additional process above given from the *Edinburgh Pharmacopœia* may prove useful.

Properties. Chloride of barium is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with beveled edges. It dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 222° , the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol, impregnated with it, burns with a yellow flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates, and tartrates, and the alkaline phosphates, borates, and carbonates; also by nitrate of silver, acetate and phosphate of mercury, and acetate of lead. When pure, it does not deliquesce. Its solution is not affected by ammonia, which proves the absence of alumina and sesquioxide of iron, or by sulphuretted hydrogen, which shows, that neither copper nor lead is present. After the whole of the barium has been precipitated by an excess of sul-

phuric acid, the supernatant liquid is shown to be free from lime by the non-action of carbonate of soda. If strontia be present, its alcoholic solution will burn with a red flame. Like all the soluble salts of barium, it is poisonous. It consists of one eq. of chlorine 35·42, one of barium 68·7, and two of water 18=122·12. It is used in medicine only in solution.

Off. Prep. Liquor Barii Chloridi, *U. S., Lond., Ed., Dub.* B.

LIQUOR Barii CHLORIDI. *U. S., Lond.* SOLUTIO BARYTÆ MURIATIS. *Ed.* BARYTÆ MURIATIS AQUA. *Dub.* *Solution of Chloride of Barium. Solution of Muriate of Baryta.*

“Take of Chloride of Barium *an ounce*; Distilled Water *three fluid-ounces*. Dissolve the Chloride of Barium in the Water, and filter.” *U. S.*

“Take of Chloride of Barium *a drachm*; Distilled Water *a fluidounce* [Imperial measure]. Dissolve the Chloride of Barium, and strain.” *Lond.*

The *Edinburgh* formula is the same as the London.

“Take of Muriate of Baryta *one part*; Distilled Water *three parts*. Dissolve. The sp. gr. of this solution should be 1·230.” *Dub.*

Chloride of barium, not being used in the solid state, is here dissolved for convenient exhibition. The *U. S.* and *Dublin* solutions are of about the same strength. The *London* and *Edinburgh* preparations are much weaker, an ounce of the salt being dissolved in eight fluidounces of water, instead of three, as directed in the *United States Pharmacopœia*. The solution should be limpid and colourless; and to make it so, the salt in crystals, and not in powder, should be employed. The *U. S.* and *Dublin* solutions are nearly saturated ones, and are probably too strong for convenient use.

Medical Properties and Uses. This solution is deobstruent and anthelmintic, and in large doses poisonous; its action, according to some, being analogous to that of arsenic. It was introduced into practice by Dr. Crawford as a remedy for cancer and scrofula. Its value in the latter disease has been particularly insisted on by Hufeland. This physician considers it to act more particularly on the lymphatic system, in the irritated states of which he esteems it a valuable remedy. Hence he recommends it in the scrofulous affections of delicate and irritable organs, such as the eyes, lungs, &c. In the commencement of scrofulous phthisis, he views it as one of the best remedies to which we can have recourse. It is employed also in diseases of the skin, in ulcers, and ophthalmia. The dose for an adult of the *U. S.* solution is about five drops, given twice or thrice a day, and gradually but cautiously increased, until it produces nausea, or some other sensible impression. When taken in an over-dose it causes violent vomiting and purging, vertigo, and other dangerous symptoms. To combat its poisonous effects, recourse must be had immediately to a weak solution of sulphate of magnesia, which acts by converting the poison into the insoluble sulphate of baryta. If vomiting does not come on, it should be induced by tickling the fauces, or by the administration of an emetic.

B.

BISMUTHUM.

Bismuth.

BISMUTHI SUBNITRAS. *U. S., Dub.* BISMUTHI TRISNITRAS. *Lond.* BISMUTHUM ALBUM. *Ed.* *Subnitrate of Bismuth. Tris-nitrate of Bismuth. White Oxide of Bismuth.*

“Take of Bismuth, in fragments, *an ounce*; Nitric Acid *a fluidounce* and

a half; Distilled Water *a sufficient quantity*. Mix a fluidounce of Distilled Water with the Nitric Acid, and dissolve the Bismuth in the mixture. When the solution is complete, pour the clear liquor into three pints of Distilled Water, and set the mixture by that the powder may subside. Lastly, having poured off the supernatant fluid, wash the Subnitrate of Bismuth with Distilled Water, wrap it in bibulous paper, and dry it with a gentle heat." *U. S.*

"Take of Bismuth *an ounce*; Nitric Acid *a fluidounce and a half* [Imperial measure]; Distilled Water *three pints* [Imp. meas.]. Mix a fluidounce of the Distilled Water with the Nitric Acid, and dissolve the Bismuth in them. Then pour off the solution. To this add the remainder of the Water, and set by that the powder may subside. Afterwards, pour off the supernatant liquor, wash the Trisnitrate of Bismuth with Distilled Water, and dry it with a gentle heat." *Lond.*

"Take of Bismuth, in fine powder, *an ounce*; Nitric Acid [of commerce?] (D. 1.380) *a fluidounce and a half* [Imperial measure]; Water *three pints* [Imp. meas.]. Add the metal gradually to the acid, favouring the action with a gentle heat, and adding a very little Distilled Water so soon as crystals or a white powder may begin to form. When the solution is complete, pour the liquor into the Water. Collect the precipitate immediately on a calico filter, wash it quickly with cold water, and dry it in a dark place." *Ed.*

"Take of Bismuth, in powder, *seven parts*; Diluted Nitric Acid *twenty parts*; Distilled Water *one hundred parts*. Add the Bismuth gradually to the Acid, and dissolve by the assistance of heat. Mix the solution with the Water, and set the mixture by that the powder may subside. Wash this with Distilled Water, and dry it on bibulous paper with a gentle heat." *Dub.*

When bismuth is added to dilute nitric acid, red fumes are copiously given off, and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder, so as to form a solution of the nitrate of bismuth. It is unnecessary to have the metal in powder, as it dissolves with great facility when added to the acid in fragments. When the solution is completed, the liquor should be added to the water, which should be distilled, and not the water to the solution, which is not so eligible a plan. Immediately on the contact of the solution with the water, four eqs. of the nitrate are resolved into one eq. of ternitrate of bismuth which remains in solution, and one eq. of trisnitrate which precipitates. In order to have a smooth light powder, which is most esteemed, the precipitate should be washed and dried as speedily as possible.

Properties. Subnitrate of bismuth is a tasteless, inodorous, heavy powder, of a pure white colour. It is slightly soluble in water, and readily so in the strong acids, from which it is precipitated by water. The fixed alkalies dissolve it sparingly, and ammonia more readily. It is darkened by hydrosulphuric acid gas, but not by exposure to light, unless it contains a little silver, or is subjected to the influence of organic matter. If it dissolves in nitric acid without effervescence, it contains no carbonate, and if the nitric solution is not precipitated by diluted sulphuric acid, it is free from lead. By the earlier chemists it was called *magistery of bismuth*. The perfumers, by whom it is sold as a paint for the complexion, denominate it *pearl white*. It consists of one eq. of nitric acid 54.15, and three of protoxide of bismuth 237=291.15.

Medical Properties and Uses. This preparation is tonic and antispasmodic. It was originally introduced into practice by Dr. Odier of Geneva,

and has been subsequently employed with advantage both in this country and in Europe. It has been recommended in epilepsy, palpitation of the heart, and spasmodic diseases generally; but more particularly in various painful affections of the stomach, dependent on disordered digestion, such as cardialgia, pyrosis, and gastrodynia. Its use always blackens the stools, from the effect of the intestinal gases. The dose is five grains, gradually increased to twelve or fifteen, twice or thrice a day, and may be taken in pill, or mixed with an equal weight of aromatic powder. In an over-dose it produces alarming gastric distress, nausea, vomiting, diarrhœa or constipation, colic, heat in the breast, slight rigors, vertigo, and drowsiness. The remedies are bland and mucilaginous drinks; and, in case of inflammation, bleeding by leeches or venesection, enemata, and emollient fomentations. B.

CALX.

Preparations of Lime.

LIQUOR CALCIS. *U. S.*, *Lond.* AQUA CALCIS. *Ed.*, *Dub.*
Lime-water.

“Take of Lime *four ounces*; Distilled Water *a gallon*. Upon the Lime, first slaked with a little of the Water, pour the remainder of the Water, and stir them together; then immediately cover the vessel and set it aside for three hours. Keep the solution, together with the undissolved Lime, in stopped glass bottles, and pour off the clear liquor when it is wanted for use. Water free from saline or other obvious impurity may be employed in this process, though not distilled.” *U. S.*

The *London College* takes *half a pound* of lime, and *twelve pints* [Imperial measure] of distilled water, and proceeds as above directed.

“Take any convenient quantity of Water, pour a little of it over about a twentieth of its weight of Lime; when the Lime is slaked, add to it the rest of the Water in a bottle; agitate well; allow the undissolved matter to subside; pour off the clear liquor when it is wanted, replacing it with more water, and agitating briskly as before.” *Ed.*

“Take of fresh burnt Lime, boiling Water, each, *one part*. Put the Lime into an earthen vessel, and sprinkle the Water upon it, keeping the vessel closed while the Lime grows hot and falls into powder; then pour upon it *thirty parts* of cold water, and, having again closed the vessel, shake the mixture frequently for twenty-four hours; lastly, after the lime has subsided, pour off the clear solution, and keep it in closely stopped bottles.” *Dub.*

A solution of lime in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water employed to dissolve it. According to all the Pharmacopœias, except the Dublin, the solution is to be kept in bottles with a portion of undissolved lime, which causes it always to be saturated, whatever may be the temperature, and to whatever extent it may be exposed to the air. By taking care to have a considerable quantity of the solution in the bottle, and avoiding unnecessary agitation, the upper portion will always remain sufficiently clear for use. The direction of the Edinburgh College, to replace by more water the clear liquid poured off, cannot, of course, be carried into effect indefinitely. By the absorption of carbonic acid, the lime is gradually converted into a carbonate, and thus rendered insoluble. The employment of Distilled Water as the solvent may seem a useless refinement; and it certainly is unnecessary when pure spring or river water

is attainable; but in many places the common water is very impure, and wholly unfit for a preparation, one of the most frequent uses of which is to allay irritability of stomach. Water dissolves but a minute proportion of lime, and contrary to the general law, less when hot than cold. Hence the propriety of employing cold water in the process. According to Mr. Phillips, a pint of water at 212° dissolves 5.6 grains of lime, at 60° , 9.7 grains, and at 32° , 11.0 grains.* When a cold saturated solution is heated, a deposition of lime takes place.

Properties. Lime-water is colourless, inodorous, and of a disagreeable alkaline taste, changes vegetable blues to green, and forms an imperfect soap with oils. Exposed to the air it attracts carbonic acid, and becomes covered with a pellicle of insoluble carbonate of lime, which, subsiding after a time, is replaced by another, and so on successively till the whole of the lime is exhausted. Hence the necessity of keeping lime-water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime.

Medical Properties and Uses. Lime-water is antacid, tonic, and astringent, and is very usefully employed in dyspepsia with acidity of stomach, diarrhœa, diabetes, and gravel attended with superabundant secretion of uric acid. Mixed with an equal measure of milk, which completely covers its offensive taste, it is one of the best remedies in our possession for nausea and vomiting dependent on irritability of stomach. We have found a diet exclusively of lime-water and milk to be more effectual than any other plan of treatment in dyspepsia accompanied with vomiting of food. In this case one part of the solution to two or three parts of milk is usually sufficient. Lime-water is also thought to be useful by dissolving the intestinal mucus in cases of worms and other complaints connected with an excess of this secretion. Externally it is employed as a wash in tinea capitis and scabies, as an application to foul and gangrenous ulcers, as an injection in leucorrhœa and ulceration of the bladder or urethra, and, mixed with linseed or olive oil, as a liniment in burns and scalds.

The dose is from two to four fluidounces taken several times a day. When employed to allay nausea, it is usually given in the dose of a table-spoonful mixed with the same quantity of new milk, and repeated at intervals of half an hour, an hour, or two hours. If too long continued it debilitates the stomach.

Off. Prep. Aqua Calcis Composita, *Dub.*; Infusum Sarsaparillæ Compositum, *Dub.*; Linimentum Calcis, *U. S., Ed., Dub.* W.

AQUA CALCIS COMPOSITA. *Dub. Compound Lime-water.*

“Take of Guaiacum Wood, rasped, *half a pound*; Liquorice Root, sliced and bruised, *an ounce*; Sassafras Bark, bruised, *half an ounce*; Coriander Seeds *three drachms*; Lime-water *six pints*. Macerate without heat, for two days, in a close bottle, occasionally shaking, and filter.” *Dub.*

This is a very inert preparation, and should be ranked among the infusions, as the lime-water can scarcely fail to be decomposed during the process. W.

CALCIS CARBONAS PRÆCIPITATUM. *Dub. Precipitated Carbonate of Lime.*

“Take of Water of Muriate of Lime *five parts*. Add *three parts* of

* These numbers may not, at first sight, appear to agree with those given in Phillips's Translation of the London Pharmacopœia of 1836; but the disagreement is only apparent, and arises from the difference between the Imperial and wine pint, the former of which is in use in England, and the latter in this country.

Carbonate of Soda, dissolved in four times its weight of Distilled Water. Wash the precipitate three times with a sufficient quantity of water; then collect it and dry it on a chalk-stone, or on bibulous paper." *Dub.*

In this process a mutual interchange of principles takes place, resulting in the production of chloride of sodium which remains in solution, and carbonate of lime which is deposited. Of crystallized carbonate of soda 143.42 parts decompose 55.92 of chloride of calcium. The Dublin water of muriate of lime contains two parts in nine of chloride of calcium. From these data it may be deduced, that the carbonate of soda in this formula is in very slight excess. The precipitated carbonate of lime is very pure and finely divided, but probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness.

Off. Prep. Hydrargyrum cum Creta, *Dub.*

W.

CRETA PRÆPARATA. *U.S., Lond., Ed., Dub. Prepared Chalk.*

"Take of Chalk a convenient quantity. Add a little water to the Chalk, and rub it into a fine powder. Throw this into a large vessel nearly full of water, stir briskly, and, after a short interval, pour the supernatant liquor, while yet turbid, into another vessel. Repeat the process with the chalk remaining in the first vessel, and set the turbid liquor by, that the powder may subside. Lastly, pour off the water, and dry the powder." *U.S.*

The *London College* takes a pound of chalk, and proceeds as above, except that it does not repeat the process with that which remains after the first operation. The processes of the *Edinburgh* and *Dublin Colleges* are essentially the same as that of the *United States Pharmacopœia*. Both Colleges direct the chalk to be powdered in a mortar. The *Edinburgh* orders it, after having been prepared, to be dried on a filter of linen or calico, the *Dublin*, on an absorbent stone or paper.

The object of these processes is to reduce chalk to very fine powder. The mineral, previously pulverized, is rubbed with a little water upon a porphyry slab, by means of a rubber of the same material, and having been thus very minutely divided, is agitated with water, which upon standing a short time deposits the coarser particles, and being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation*, the latter *elutriation*. The soft mass which remains after the decanting of the clear liquor, is made to fall upon an absorbent surface in small portions, which when dried have a conical shape.

Medical Properties and Uses. This is the only form in which chalk is used in medicine. It is an excellent antacid; and as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to diarrhœa accompanied with acidity. It is also sometimes used in acidity of stomach attending dyspepsia and gout, when a laxative effect is to be avoided; is one of the best antidotes for oxalic acid; and has been recommended in rachitis. In scrofulous affections it may sometimes do good by forming soluble salts with acid in the primæ viæ, and thus finding an entrance into the blood-vessels. It is frequently employed as an application to burns and ulcers, the ichorous discharge from which it absorbs, and thus prevents from irritating the diseased surface or the sound skin. It probably also does good, in these cases, by a peculiar action upon the part to which it is applied. It is given internally in the form of powder, or suspended in water by the intervention of gum Arabic and sugar. (See *Mistura Cretæ*.) The dose is from ten to forty grains or more.

Off. Prep. Confectio Aromatica, *Lond., Dub.*; Hydrargyrum cum Cretâ, *U. S., Lond., Ed., Dub.*; Mistura Cretæ, *U. S., Lond., Ed., Dub.*; Pulvis Cretæ Compositus, *Lond., Ed., Dub.*; Trochisci Cretæ, *U. S., Ed.*; Unguentum Plumbi Compositum, *Lond.* W.

TESTA PRÆPARATA. *U. S.* TESTÆ PRÆPARATÆ. *Lond.*
Prepared Oyster-shell.

“Take of Oyster-shell *a convenient quantity*. Free it from extraneous matter, wash it with boiling water, and reduce it to powder; then prepare it in the manner directed for Chalk.” *U. S.*

The *London College* gives similar directions.

Prepared oyster-shell differs from prepared chalk in containing animal matter, which, being very intimately blended with the carbonate of lime, is supposed by some physicians to render the preparation more acceptable to a delicate stomach. It is given as an antacid in diarrhœa, in the dose of from ten to forty grains or more, frequently repeated. W.

LIQUOR CALCII CHLORIDI. *U. S., Lond.* CALCIS MURIATIS SOLUTIO. *Ed.* CALCIS MURIATIS AQUA. *Dub.* *Solution of Chloride of Calcium. Solution of Muriate of Lime.*

“Take of Marble, in fragments, *nine ounces*; Muriatic Acid *a pint*; Distilled Water *a sufficient quantity*. Mix the Acid with half a pint of the Distilled Water, and gradually add the Marble. Towards the close of the effervescence apply a gentle heat, and, when the action has ceased, pour off the clear liquor and evaporate to dryness. Dissolve the residuum in its weight and a half of Distilled Water, and filter the solution.” *U. S.*

The *London College* dissolves *four ounces* of chloride of calcium in *twelve fluidounces* [Imperial measure] of distilled water, and filters through paper. The *Edinburgh College* dissolves *eight ounces* of muriate of lime [chloride of calcium] in *twelve fluidounces* [Imp. meas.] of water. The *Dublin College* dissolves *two parts* of the salt in *seven parts* of distilled water, and states the sp. gr. of the solution at 1·202.

By the *U. S.* process a chloride of calcium is first formed, and then, as in the other processes, is dissolved in a certain proportion of water. The *U. S.* and *Edinburgh* preparations agree very nearly in strength, containing 1 part of the chloride in about 2·5 parts of the solution. Those of the *London* and *Dublin Colleges* are only about half as strong; the latter containing 1 part of the chloride in 4·5 of the solution.

The solution of chloride of calcium has a disagreeable, bitter, acrid taste. It is decomposed by sulphuric acid and the soluble sulphates; by potassa, soda, and their carbonates; by carbonate of ammonia, tartrate of potassa and soda, nitrate of silver, nitrate and acetate of mercury, and acetate of lead. The mode of preparing chloride of calcium, and its chemical properties, are detailed under the head of *Calcii Chloridum* in the first part of this work.

Medical Properties and Uses. Chloride of calcium is considered tonic and deobstruent, and is said to promote the secretion of urine, perspiration, and mucus. It was first brought into notice as a remedy by Foureroy, and was at one time much used in scrofulous diseases and goitre. It still continues to be a favourite with some physicians, but is less employed than formerly. It has been especially recommended in *tabes mesenterica*. When too largely taken it sometimes produces nausea, vomiting, and purging, and in excessive doses may even produce fatal effects; but it is a much safer remedy than chloride of barium, which has been recommended in the same complaints. The dose of the solution is from thirty minims or drops to a fluidrachm, to be repeated twice or three times a day, and gradually increased to two,

three, or even four fluidrachms. It may be given in milk or sweetened water.

Off. Prep. Calcis Carbonas Præcipitatum. *Dub.*

W.

CALCIS PHOSPHAS PRÆCIPITATUM. *Dub. Precipitated Phosphate of Lime.*

“Take of Burnt Bones, in powder, *one part*; Diluted Muriatic Acid, Water, each, *two parts*. Digest together for twelve hours, and filter the solution. Add as much Water of Caustic Ammonia as will be sufficient to precipitate the Phosphate of Lime. Wash this with a large proportion of water, and finally dry it.” *Dub.*

The muriatic acid dissolves the phosphate of lime of the bones, and lets it fall on the addition of ammonia, in a state of minute division. The ablu-tion is intended to free it from any adhering muriate of ammonia. The salt thus obtained is, for the sake of distinction, called *bone-phosphate of lime*. It is in the form of a white powder, without taste or smell, insoluble in water, but very soluble in nitric, muriatic, and acetic acids, from which it is precipitated unchanged on the addition of ammonia. By an intense heat it is fused, but is not otherwise changed. It consists of eight equivalents of lime and three of phosphoric acid.

The chemical characteristics of bone-phosphate of lime, besides those mentioned, are that with its solution in dilute nitric acid, oxalate of ammonia produces a white precipitate of oxalate of lime, and acetate of lead a white precipitate of phosphate of lead; and, if the nitric solution be neutralized as far as possible without causing a permanent precipitate of phosphate of lime, ammoniacal nitrate of silver throws down from it a lemon-yellow precipitate of phosphate of silver. (*Christison's Dispensatory.*)

If this preparation possesses any advantage over burnt hartshorn, it is in the state of minute division to which it has been brought by precipitation. It may be given in the same complaints and in the same dose; but is probably quite inert. (See *Cornu Ustum.*)

W.

CORNU USTUM. *Lond.* **PULVIS CORNU CERVINI USTI.** *Dub.*
Burnt Hartshorn.

“Burn pieces of Hartshorn in an open vessel until they are thoroughly white; then powder them, and prepare them in the manner directed for Chalk.” *Lond.*

The *Dublin College* gives similar directions.

The horn must not only be heated, but also burnt, in order that the animal matter may be entirely consumed. The operation may be performed in a common furnace or stove, the air being freely admitted. Care should be taken that the heat be not too violent, as otherwise the external surface of the horn may become vitrified, and prevent the complete combustion of the interior portion, while it is itself rendered less fit for use. Burnt hartshorn consists of bone-phosphate of lime, with a minute proportion of lime, derived from the carbonate contained in the horns. It may be inferred, from the analysis of hartshorn by M. Guillot, that the proportion of free lime in this preparation is less than one per cent. (See *Cornu.*) Bone-earth is usually sold in the shops for burnt hartshorn. For the chemical characteristics of bone-phosphate of lime, see *Calcis Phosphas Præcipitatum*.

Medical Properties and Uses. The opinion formerly entertained, that burnt hartshorn was antacid, has been abandoned since the discovery of its chemical nature. Its composition suggested its application to the cure of

rachitis and mollities ossium, of which the prominent character is a deficiency of phosphate of lime in the bones; and it is said to have been employed in some cases, in connexion with phosphate of soda, with apparent success. Experience, however, has not confirmed the first report in its favour. It is probably altogether inert. The dose is twenty grains or more. W.

CARBO ANIMALIS.

Preparation of Animal Charcoal.

CARBO ANIMALIS PURIFICATUS. *U. S., Lond., Ed. Purified Animal Charcoal.*

“Take of Animal Charcoal *a pound*; Muriatic Acid, Water, each, *twelve fluidounces*. Pour the Muriatic Acid, previously mixed with the Water, gradually upon the Charcoal, and digest with a gentle heat for two days, occasionally stirring the mixture. Having allowed the undissolved portion to subside, pour off the supernatant liquor, wash the Charcoal frequently with water until it is entirely free from acid, and lastly dry it.” *U. S.*

The processes of the London and Edinburgh Pharmacopœias are essentially the same as the above. The Edinburgh College, after washing the charcoal, gives the additional direction of heating it first moderately, and then to redness in a closely covered crucible. This ignition is essential to the full development of its decolorizing power.

The nature and properties of animal charcoal have been explained under another head. (See *Carbo Animalis*.) As it is made by charring bones, it necessarily contains bone-phosphate and carbonate of lime, the presence of which does no harm in some decolorizing operations; but in delicate chemical processes, such as those connected with the preparation of the organic alkalis, these salts would be dissolved or decomposed, and thus be a source of impurity. It is for these reasons that animal charcoal requires to be purified from the calcareous salts which it contains; and this is effectually accomplished by dilute muriatic acid, which dissolves the phosphate and decomposes the carbonate.

Purified animal charcoal is a dark brownish-black powder. It should be entirely free from carbonate and phosphate of lime. It may be tested with muriatic acid, which should not dissolve anything. If the charcoal contain carbonate of lime, muriatic acid will cause effervescence, and the solution obtained will give a precipitate with carbonate of ammonia. If it contain phosphate of lime, the acid will dissolve the salt and yield it as a precipitate on the addition of ammonia. The Edinburgh College directs animal charcoal to be tested by incinerating it with its volume of red oxide of mercury, when, if good, it will be dissipated with the exception of a scanty ash.

CATAPLASMATA.

Cataplasms.

Cataplasms or poultices are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over

the neighbouring parts, or so tenacious as to adhere firmly to the skin. As they are in this country scarcely ever prepared by the apothecary, they were not deemed by the compilers of the United States Pharmacopœia proper objects for official direction.

W.

CATAPLASMA ALUMINIS. *Dub. Alum Cataplasm.*

"Take the Whites of *two Eggs*; of Alum *a drachm.* Shake them together so as to make a coagulum." *Dub.*

A common mode of preparing the alum poultice, is to rub the whites of eggs briskly in a saucer with a lump of alum till the liquid coagulates. The curd produced by coagulating milk with alum is sometimes used as a substitute.

The alum cataplasm is an astringent application, occasionally employed in incipient, purulent, or chronic ophthalmia. It is placed over the eye enclosed between folds of cambric or soft linen. It is also esteemed useful in chilblains when the skin is not broken.

W.

CATAPLASMA CARBONIS LIGNI. *Dub. Charcoal Cataplasm.*

"Take a *sufficient quantity* of Wood Charcoal red hot from the fire, and, having extinguished it by sprinkling dry sand over it, reduce it to very fine powder, and incorporate it with the Simple Cataplasm in a tepid state." *Dub.*

Charcoal, recently prepared, has the property of absorbing those principles upon which the offensive odour of putrefying animal substances depends. In the form of poultice it is an excellent application to foul and gangrenous ulcers, correcting their fetor, and improving the condition of the sore. It should be frequently renewed.

W.

CATAPLASMA CONII. *Lond., Dub. Hemlock Cataplasm.*

"Take of Extract of Hemlock *two ounces*; Water *a pint* [Imperial measure]. Mix, and add of bruised Flaxseed sufficient to produce a proper consistence." *Lond.*

"Take of Dried Hemlock Leaves *an ounce*; Water *a pint and a half*. Boil down to a pint, and having strained the liquor, add as much of the powdered leaves as may be sufficient to form a cataplasm." *Dub.*

This cataplasm may be advantageously employed as an anodyne application to cancerous, scrofulous, syphilitic, and other painful ulcers: but its liability to produce narcotic effects by the absorption of the active principle of the hemlock should not be overlooked.

W.

CATAPLASMA DAUCI. *Dub. Carrot Cataplasm.*

"Take of the Root of the cultivated Carrot *any quantity*. Boil the root in water until it becomes sufficiently soft to form a cataplasm." *Dub.*

Emollient poultices may be prepared from any of the tender culinary roots, from turnips and potatoes as well as carrots, by boiling them, removing the skin, and mashing them into a soft pulp, which may be rendered uniform by pressing it through a coarse sieve or colander. But these poultices possess no specific power, and act on the same principle with those made with bread and milk, and flaxseed meal.

The carrot cataplasm, when designed to produce a peculiar impression, should be made by grating the fresh roots. Thus prepared it is slightly stimulating, and is useful in weak, flabby, ill-conditioned, and offensive ulcers. By boiling, the stimulant property is diminished, if not lost; and the carrot becomes a mild and nutritive article of food.

W.

CATAPLASMA FERMENTI. *Lond.* CATAPLASMA FERMENTI CEREVISIÆ. *Dub.* *Yeast Cataplasm.*

"Take of Flour [wheat flour] *a pound*; Yeast *half a pint* [half a pound, *Dub.*]. Mix and expose the mixture to a gentle heat until it begins to rise." *Lond., Dub.*

By exposing a mixture of yeast and flour to a gentle heat, fermentation takes place, and carbonic acid gas is extricated, which causes the mixture to swell and is the source of its peculiar virtues. The yeast cataplasm is gently stimulant, and is sometimes applied with much benefit to foul and gangrenous ulcers, the fetor of which it corrects, while it is supposed to hasten the separation of the slough. W.

CATAPLASMA LINI. *Lond.* *Flaxseed Cataplasm.*

"Take of boiling Water *a pint*; Flaxseed, powdered, sufficient to produce a proper consistence. Mix them." *Lond.*

CATAPLASMA SIMLPEX. *Dub.* *Simple Cataplasm.*

"Take of the Powder for a Cataplasm *any quantity*; Boiling Water sufficient to form a tepid cataplasm, the surface of which should be covered with olive oil." *Dub.*

The Dublin "Powder for a Cataplasm," consists of one part of flaxseed meal remaining after the expression of the oil, and two parts of oat meal. Flaxseed meal which has not been submitted to pressure is decidedly preferable, and answers an excellent purpose when mixed with boiling water, without other addition, as in the London flaxseed cataplasm. Fresh lard or olive oil spread upon the surface of the poultice serves to prevent its adhesion to the skin, and to preserve its softness.

The use of this and other emollient cataplasms is to relieve the tense condition of the vessels in inflammation, and to promote suppuration. They act simply by their warmth and moisture. The one most extensively employed, perhaps because its materials are always at hand, is that prepared by heating together milk and the crumb of bread. The milk should be quite sweet, and fresh lard should be incorporated with the poultice. Mush made with the meal of Indian corn also forms an excellent emollient cataplasm. W.

CATAPLASMA SINAPIS. *Lond., Dub.* *Mustard Cataplasm.*

"Take of Flaxseed, Mustard [seed], each, in powder, *half a pound*; boiling Vinegar, sufficient to produce the consistence of a cataplasm." *Lond.*

The *Dublin College* orders the same seeds in the same proportion, and states that the cataplasm may be made more stimulating by the addition of *two ounces* of scraped horse-radish.

The simplest and most effectual mode of preparing a mustard poultice, is to mix the powdered mustard of the shops with a sufficient quantity of warm water to give it a due consistence. When a weaker preparation is required, an equal portion or more of rye or wheat flour should be added. Vinegar never increases its efficiency, and, in the case of the black mustard seed, has been ascertained by MM. Trousseau and Blanc to diminish its rubefacient power. A boiling temperature is also injurious by interfering with the development of the volatile oil or acrid principle. (See *Sinapis*.)

These poultices are frequently called *sinapisms*. They are powerfully rubefacient, exciting a sense of warmth in a few minutes, and usually becoming insupportably painful in less than an hour. When removed, they leave the surface intensely red and burning; and the inflammation fre-

quently terminates in desquamation, or even blistering, if the application has been too long continued. Obstinate ulcers and gangrene also sometimes result from the protracted action of mustard, especially on parts possessed of little vitality. As a general rule, the poultice should be removed when the patient complains much of the pain; and in cases of insensibility should not, unless greatly diluted, be allowed to remain longer than one, or at most two hours; as violent inflammation, followed by obstinate ulceration, is apt to occur upon the establishment of reaction in the system. In children also particular care is necessary to avoid this result. The poultice should be thickly spread on linen, and may be covered with gauze or unsized paper in order to prevent its adhesion to the skin. If hairs are present they should be removed by the razor. Sinapisms may be employed in all cases in which it is desirable to produce a speedy and powerful rubefacient impression. W.

CERATA.

Cerates.

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or resin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should usually be taken to select the oil or lard perfectly free from rancidity. The liquefaction should be effected by a very gentle heat, which may be applied by means of a water-bath; and during the refrigeration the mixture should be well agitated, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the whole assumes the proper consistence. When a large quantity is prepared, the mortar, or other vessel into which the mixture may be poured for cooling, should be previously heated by means of boiling water. W.

CERATUM CANTHARIDIS.* U. S. EMPLASTRUM CANTHARIDIS, *Lond., Ed., Dub.* EMPLASTRUM EPISPASTICUM. *Cerate of Spanish Flies. Blistering Plaster.*

“Take of Spanish Flies, in very fine powder, *a pound*; Yellow Wax, Resin, Lard, each, *eight ounces*. To the Wax, Resin, and Lard, previously melted together, add the Spanish Flies, and stir the mixture constantly until cool.” U. S.

The *London College* orders *a pound* of Spanish flies, *a pound and a half* of wax plaster, and *half a pound* of lard; the *Edinburgh*, *two ounces*, each, of flies, resin, yellow wax, and suet; and the *Dublin*, *a pound* of flies, *a pound* of yellow wax, *four ounces* of yellow resin, *half a pound* of suet, and *half a pound* of lard.

This is the common *blistering plaster* of the shops. As it can be readily spread without the aid of heat, it is properly a cerate, and is therefore correctly named in the U. S. Pharmacopœia. Though essentially the same in character as prepared by the different processes, it varies somewhat in strength. The U. S. and London preparations have the same proportion of flies, but are stronger than those of the Edinburgh and Dublin Colleges.

* This is a different preparation from the London *Ceratum Cantharidis*.

One of the two former therefore is preferable, and our own has this advantage, that it does not require the previous preparation of the wax plaster. Care has usually been considered requisite, in making the cerate, not to injure the flies by heat. It has, therefore, been recommended that they should not be added to the other ingredients, until immediately before these begin to stiffen after having been removed from the fire. But from the experiments of Mr. Donovan (*Dublin Med. Press*, Aug. 1840), and those of Mr. Wm. Procter (*Am. Journ. of Pharm.* xiii. 302), there is reason to believe that the vesicating principle of Spanish flies is not injured or dissipated by a heat under 300° F., and that an elevated temperature, instead of being hurtful, is positively advantageous in the preparation of the blistering cerate. The cantharidin is thus more thoroughly dissolved by the oleaginous matter, and consequently brought more efficiently into contact with the skin, than when retained in the interior of the tissue of the fly. Another advantage stated by Donovan is, that the moisture which usually exists to a certain extent in all the ingredients of the cerate is thus dissipated, and the preparation is less apt to become mouldy, or otherwise to undergo decomposition. Instead, therefore, of waiting until the melted wax, resin, and lard begin to stiffen, it is better to add the powder before the vessel is removed from the fire. Mr. Donovan recommends that as soon as the other ingredients are melted, the powdered flies should be added, and the mixture stirred until the heat is shown by a thermometer to have risen to 250° , when the vessel is to be removed from the fire, and the mixture stirred constantly until cool. At the heat mentioned, ebullition takes place in consequence of the escape of the moisture contained in the materials. In the cerate thus prepared the active matter has been dissolved by the lard, and the powder may be separated, if deemed advisable, by straining the mixture before it solidifies. Care should be taken that the temperature be not so high as to decompose the ingredients; and it would be better to keep it within 212° by means of a water-bath, than to incur any risk from its excess. It is desirable also that the flies should be very finely pulverized. Powdered euphorbium is said to be sometimes fraudulently substituted for a portion of the flies.

The cerate is the most convenient form in which cantharides can be applied for the purpose of raising a blister, and it is always effectual in ordinary conditions of the system, if the flies are good and not injured in the preparation. It should be spread on soft leather, though linen or even paper will answer the purpose when this is not to be had. An elegant mode of preparing it for use, is to spread a piece of leather of a proper size first with adhesive plaster, and afterwards with the cerate, leaving a margin of the former uncovered, in order that it may adhere to the skin. Heat is not requisite, and should not be employed in spreading the cerate. It is customary with some to sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but if the flies originally employed were good, this addition is superfluous.

Upon the application of the plaster, the skin should be moistened with warm vinegar or other liquid; and a good rule is to cover the surface of the plaster closely with very thin gauze or unsized paper, which prevents any of the cerate from adhering to the cuticle, and is thought by some to diminish its liability to occasion strangury. In the cases of adults, when the full operation of the flies is desirable, and the object is to produce a permanent effect, the application should be continued for twelve hours, and upon the scalp for twenty-four hours. In very delicate persons, however, or those

subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as speedily as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a bread and milk poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum.* In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied. From two to four hours are usually sufficient to answer any desirable purpose. When the head, or other very hairy part is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster; so that the abrasions of the cuticle may heal, and some obstacle be offered to the absorption of the active principle of the flies. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but if it be desirable to maintain the discharge for a short time, resin cerate should be used, and the cuticle removed, if it can be done without inconvenience. The effects of an issue may be obtained by employing savine ointment, or the ointment of Spanish flies, as a dressing. If much inflammation should take place in the blistered surface, it may be relieved by emollient poultices, or weak lead-water. Where there is an obstinate indisposition to heal, we have found nothing so effectual as the cerate of subacetate of lead, diluted with an equal weight of simple cerate. When deep and extensive ulceration occurs in consequence of general debility, bark or sulphate of quinia should be used with nutritious aliment.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting the *blistering cloth*, *blistering paper*, *vesicating taffetas*, &c. of the shops. The advantages of these preparations are that they occupy less space, are more portable, and, being very pliable, are more easily adapted to irregularities of the surface. Absolutely pure cantharidin is expensive and not requisite; as the extract of cantharides made with ether or boiling alcohol will answer every purpose. Henry and Guibourt give the following formula. Digest powdered cantharides in sulphuric ether, distil off the ether, evaporate the residue by means of a salt-water bath until ebullition ceases, melt the oily mass which remains with twice its weight of wax, and spread the mixture upon waxed cloth. The *waxed cloth* may be prepared by spreading upon linen or muslin a mixture composed of 8 parts of white wax, 4 of olive oil, and 1 of turpentine, melted together. A strong decoction of the flies in olive oil or oil of turpentine, applied by means of paper, would probably answer a similar purpose with these more elaborate preparations. But none of them is likely to supersede the officinal cerate. For very speedy vesication, an infusion of the flies in strong acetic acid is sometimes employed. (See *Acetum Cantharidis*.)

It is said that, by ebullition with water, the flies are deprived of their pro-

* Dr. M. B. Smith of Philadelphia, has informed us that he has frequently employed *uva ursi* as a preventive of strangury from blisters, and has never found it to fail. He gives a small wineglassful of the officinal decoction (see *Decoctum Uvæ Ursi*) every hour, commencing two hours after the application of the blister.

perty of producing strangury, while their vesicating powers remain unaltered. (*Paris's Pharmacologia*.) Dr. Theophilus Beasley, of Philadelphia, has been in the habit of employing a cerate made with cantharides prepared in this manner, and has never known it to produce strangury in more than two or three instances. He boils the *unpowdered flies* for fifteen minutes, esteeming a shorter time insufficient to deprive them of this property, while if the boiling be continued much longer, their blistering power is impaired. (*Journ. of the Phil. Col. of Pharm.* iv. 185.) In a letter addressed to one of the authors by Dr. James Couper of Newcastle, Delaware, a similar method of preparing the flies is recommended as an expedient against strangury, both from his own experience and that of the late Dr. Groom of Elkton, Maryland, from whom he derived his knowledge of the plan.

Off. Prep. Emplastrum Picis cum Cantharide, *U.S.*, *Dub.* W.

CERATUM CETACEI. *U.S.*, *Lond.* CERATUM SIMPLEX. *Ed.*
 UNGUENTUM CETACEI. *Dub.* *Spermaceti Cerate.*

"Take of Spermaceti *an ounce*; White Wax *three ounces*; Olive Oil *six fluidounces*. Melt together the Spermaceti and Wax; then add the Oil previously heated, and stir the mixture until cool." *U.S.*

The *London College* directs *two ounces* of spermaceti, *eight ounces* of white wax, and a *pint* [Imperial measure] of olive oil; the *Edinburgh*, *six parts* of olive oil, *three parts* of white wax, and *one part* of spermaceti; the *Dublin*, *half a pound* of white wax, *a pound* of spermaceti, and *three pounds* of lard.

The direction to heat the oil before adding it to the other ingredients is peculiar to the *U.S.* and *Edinburgh Pharmacopœias*. If added cold, it is apt to produce an irregular congelation of the wax and spermaceti, and thus to render the preparation lumpy. This cerate is employed as a dressing for blisters, excoriated surfaces, and wounds; and as the basis of more active preparations. When the ingredients are pure and sweet, it is perfectly free from irritating properties.

Off. Prep. Ceratum Cantharidis, *Lond.* Ceratum Calaminæ, *Ed.* W.

CERATUM HYDRARGYRI COMPOSITUM. *Lond.* *Compound Cerate of Mercury.*

"Take of Strong Mercurial Ointment, Soap Cerate, each, *four ounces*; Camphor *an ounce*. Rub them together until they are incorporated." *Lond.*

This cerate is used as a discutient application to indolent tumours. W.

CERATUM PLUMBI SUBACETATIS. *U.S.* CERATUM PLUMBI COMPOSITUM. *Lond.* *Cerate of Subacetate of Lead.* *Goulard's Cerate.*

"Take of Solution of Subacetate of Lead *two fluidounces and a half*; White Wax *four ounces*; Olive Oil *nine fluidounces*; Camphor *half a drachm*. Mix the Wax previously melted, with eight fluidounces of the Oil; then remove the mixture from the fire, and, when it begins to thicken, gradually pour in the Solution of Subacetate of Lead, stirring constantly with a wooden spatula till it becomes cool. Lastly, add the Camphor dissolved in the remainder of the Oil and mix." *U.S.*

The above process is that of the former *London Pharmacopœia*. In the last edition of that work, *three fluidounces* of the solution of subacetate of lead, and *half a pint* of olive oil, have been substituted for the quantities before employed, the process remaining in other respects unaltered. But when it is considered that the *London College* now employs the Imperial instead of the wine measure, the change will be seen to be less than it might otherwise appear.

This preparation received the name by which it is commonly known from M. Goulard, by whom it was employed and recommended. It is used to dry up excoriations, to relieve the inflammation of burns, scalds, and chilblains, and to remove cutaneous eruptions. We have found it more effectual than any other application to blistered surfaces indisposed to heal; and, on the recommendation of Dr. Parrish, have used it in the following combination with advantage in various cutaneous eruptions of a local character. Take of cerate of subacetate of lead, simple cerate, each, *half an ounce*; calomel, powdered opium, each *a drachm*; mix them. The same preparation, without the opium, was a favourite remedy with the late Dr. Wistar in similar complaints. W.

CERATUM RESINÆ. *U. S., Lond.* UNGUENTUM RESINOSUM. *Ed.* UNGUENTUM RESINÆ ALBÆ. *Dub.* Resin Cerate. *Basilicon ointment.*

"Take of Resin *five ounces*; Lard *eight ounces*; Yellow Wax *two ounces*. Melt them together, strain through linen, and stir them constantly until cool." *U. S.*

The proportions directed by the *Edinburgh College* are the same as the above. The *London College* orders of resin and wax, each, *a pound*, and of olive oil *sixteen fluidounces*. The resin and wax are melted together over a slow fire, the oil then added, and the mixture while hot strained through linen. By the *Dublin* process, *four pounds* of lard, *two pounds* of white resin, and *one pound* of yellow wax are made into an ointment, and strained while hot through a sieve.

The straining is directed in consequence of the impurities which resin often contains. Resin cerate, commonly called *basilicon ointment*, is much used as a gently stimulant application to blistered surfaces, indolent ulcers, burns, scalds, and chilblains. We have found no application more effectual in disposing the ulcers which follow burns to heal.

Off. Prep. Ceratum Sabinæ, *U. S.*; Linimentum Terebinthinæ, *U. S., Ed., Dub.*; Unguentum Cantharidis, *U. S., Lond., Ed., Dub.*; Unguentum Cupri Subacetatis, *Dub., Ed.* W.

CERATUM RESINÆ COMPOSITUM. *U. S.* Compound Resin Cerate.

"Take of Resin, Suet, Yellow Wax, each, *a pound*; Turpentine *half a pound*; Flaxseed Oil *half a pint*. Melt them together, strain through linen, and stir them constantly until cool." *U. S.*

This is somewhat more stimulating than the preceding, but is applicable to similar purposes, particularly to the treatment of indolent ulcers. Under the name of *Deshler's salve*, it is popularly employed in some parts of the United States. W.

CERATUM SABINÆ. *U. S., Lond., Ed.* UNGUENTUM SABINÆ. *Dub.* Savine Cerate.

"Take of Savine, in powder, *two ounces*; Resin Cerate *a pound*. Mix the Savine with the Cerate previously softened." *U. S.*

The *London College* orders *one pound* of fresh savine, bruised, to be mixed with *half a pound* of wax and *two pounds* of lard previously melted together, and the whole to be strained through linen. The *Edinburgh College* directs the same ingredients, in the same proportions, to be boiled together till the leaves become friable, and then strained. The *Dublin College* employs only *half a pound* of the leaves, which it directs to be

boiled in the lard till they become crisp. The lard is then to be strained with expression, the wax added, and the whole melted together.

As the savine used in this country is generally brought from Europe in the dried state, we are compelled to resort to the mode of preparing the cerate directed in the U.S. Pharmacopœia. Nor have we found the preparation thus made to be "intolerably acrid and almost caustic," as Dr. Duncan describes it. On the contrary, it answers very well the purpose for which it is used—that of maintaining the discharge from blistered surfaces. A cerate prepared in the same manner from the leaves of the red cedar (*Juniperus Virginiana*) is sometimes substituted for that of savine, but is less efficient.

Prepared according to the processes of the British Colleges, savine cerate has a fine deep-green colour, and the odour of the leaves. It should be kept in closely covered vessels, as its virtues are impaired by exposure.

Savine cerate is preferable to the ointment of Spanish flies as a dressing for perpetual blisters, from the circumstance that it has no tendency to produce strangury. The white coating which forms during its use upon the blistered surface should be occasionally removed, as it prevents the contact of the cerate. It is sometimes applied to seton cords, with the view of increasing the discharge.

W.

CERATUM SAPONIS. U.S., Lond. Soap Cerate.

"Take of Solution of Subacetate of Lead *two pints*; Soap *six ounces*; White Wax *ten ounces*; Olive Oil *a pint*. Boil the Solution of Subacetate of Lead with the Soap, over a slow fire, to the consistence of honey; then transfer to a water-bath and evaporate until all the moisture is dissipated; lastly, add the Wax previously melted with the Oil, and mix." U.S.

"Take of Soap *ten ounces*; Wax *twelve ounces and a half*; Oxide of Lead [litharge], in powder, *fifteen ounces*; Olive Oil *a pint* [Imperial measure]; Vinegar *a gallon* [Imp. meas.]. Boil the Vinegar with the Oxide of Lead, over a slow fire, constantly stirring until they unite; then add the Soap, and again boil in a similar manner, until all the moisture is dissipated; lastly, with these mix the Wax previously dissolved in the Oil." Lond.

The present U.S. formula is that of Mr. Durand, given in the American Journal of Pharmacy (vol. 8, p. 27), and was substituted, in the last edition of the Pharmacopœia, for the London formula, which had been adopted in the previous editions. It has the advantages of being more precise in the directions, more easy of execution, and more uniform in its results. It yields a perfectly white cerate, having the same properties as the London, and a finer appearance. The solution of subacetate of lead, which in the U.S. process is taken already prepared, results, in the London, from the action of the vinegar upon the litharge. In both processes, the subacetate of lead is decomposed by the soap, the soda of which unites with the acetic acid, and the oleaginous acids with the oxide of lead in the same manner as in the formation of the Emplastrum Plumbi. The wax and oil subsequently added merely serve to give due consistence to the preparation. Soap cerate is thought to be cooling and sedative; and is sometimes used in scrofulous swellings and other instances of chronic external inflammations. It was formerly employed by Mr. Pott as a dressing for fractured limbs; but answers no other purpose in these cases than to yield mechanical support.

Off. Prep. Ceratum Hydrargyri Compositum, Lond.

W.

CERATUM SIMPLEX. U.S. CERATUM. Lond. *Simple Cerate.*

"Take of Lard *eight ounces*; White Wax *four ounces*. Melt them together, and stir them constantly until cool." U. S.

The *London College* directs that *four fluidounces* of olive oil be mixed with *four ounces* of wax previously melted.

We prefer the formula of the U. S. Pharmacopœia. Lard is preferable to olive oil, as it may always be had perfectly sweet, and is the mildest application which can be made to irritated surfaces. In the preparation of this cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition; for the value of the preparation depends on its perfect blandness. It is used for dressing blisters, wounds, &c., in all cases in which the object is to exclude the external air and preserve the moisture of the part, and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose lard should be used in winter, and simple ointment in summer; the cerate having too firm a consistence. W.

CERATUM ZINCI CARBONATIS. U.S. CERATUM CALAMINÆ. Lond., Ed. UNGUENTUM CALAMINÆ. Dub. *Cerate of Carbonate of Zinc. Cerate of Calamine. Turner's Cerate.*

"Take of Prepared Carbonate of Zinc, Yellow Wax, each, *half a pound*; Lard *two pounds*. Melt the Wax and Lard together, and, when upon cooling they begin to thicken, add the Carbonate of Zinc, and stir the mixture constantly until cool." U. S.

The *London College* orders *half a pound* of [prepared] calamine, *half a pound* of wax, and *sixteen fluidounces* of olive oil; the *Edinburgh*, *one part* of prepared calamine, and *five parts* of simple cerate [*Ceratum Cetacei*, U. S.]; the *Dublin*, *one pound* of calamine, and *five pounds* of ointment of yellow wax.

This cerate is an imitation of that recommended by Turner. It is mildly astringent, and is much used in excoriations and superficial ulcerations, produced by the chafing of the skin, irritating secretions, burns, or other causes. W.

CONFECTIONES. U.S., Lond.

Confections.

CONFECTIONES; CONSERVÆ; ELECTUARIA. Dub. CONSERVES AND ELECTUARIES. Ed.

Under the general title of Confections, the Pharmacopœias of the United States and of London include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. The *Edinburgh College* retains the old division into Conserves and Electuaries; and, as there is some ground for the distinction, we shall make a few general remarks upon each division, before proceeding to the consideration of the individual preparations.

CONSERVES consist of recent vegetable substances and refined sugar beat into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But as active medicines even

thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now retained are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be reduced to a fine powder by pounding and sifting, as otherwise it will not mix uniformly with the other ingredient.

ELECTUARIES are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made in the shops, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for pharmaceutic direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary be found, after having been kept for a short time, to swell up and emit gas, it should be beat over again in a mortar, so that any portion of the sugar which may have crystallized may be again accurately incorporated with the other ingredients. Should it, on the contrary, become dry and hard from the mutual reaction of its constituents, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup, and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose; but its taste might be considered objectionable. Some persons employ honey, but this is not always acceptable to the stomach.

W.

CONFECTIO AMYGDALÆ. *Lond.* CONSERVA AMYGDALARUM. *Ed.* CONFECTIO AMYGDALARUM. *Dub.* *Almond Confection.*

“Take of Sweet Almonds *eight ounces*; Gum Arabic, in powder, *an ounce*; Sugar *four ounces*. Having macerated the Almonds in cold water, and deprived them of their external coat, beat all the ingredients together till they are thoroughly incorporated. The confection may be kept longer, if the Almonds, Gum Arabic, and Sugar, separately rubbed, should be afterwards mixed. Then, whenever the confection is to be used, beat the whole together until incorporated.” *Lond.*

The directions of the *Edinburgh* and *Dublin Colleges* are essentially the same as the above, except that these Colleges do not admit the alternative of having the ingredients separately rubbed, and afterwards mixed.

This preparation was adopted as affording a speedy method of preparing the almond mixture, which when made immediately from the Almonds requires much time, and which cannot be kept ready made in the shops. But, from its liability to be injured by keeping, it has been omitted in the last edition of our Pharmacopœia, which directs the almond mixture to be made immediately from the ingredients. (See *Mistura Amygdalæ.*) W.

CONFECTIO AROMATICA. *U.S., Lond., Dub.* ELECTUARIUM AROMATICUM. *Ed.* *Aromatic Confection.*

“Take of Aromatic Powder *five ounces and a half*; Saffron, in powder,

half an ounce; Syrup of Orange Peel six ounces; Clarified Honey two ounces. Rub the Aromatic Powder with the Saffron; then add the Syrup and Honey, and beat them together until thoroughly mixed." *U. S.*

"Take of Cinnamon, Nutmegs, each, *two ounces; Cloves an ounce; Cardamom half an ounce; Saffron two ounces; Prepared Chalk sixteen ounces; Sugar two pounds.* Rub the dry ingredients together to a very fine powder, and keep them in a closed vessel. But when the confection is to be used, add water gradually, and mix till a thorough incorporation is effected." *Lond.*

The *Dublin* formula corresponds with that of the former London Pharmacopœia, which directed the same ingredients as in the present formula, but added a *pint* of water to the dry materials and incorporated the whole together at one time. The *Edinburgh College* directs *one part* of their aromatic powder, and *two parts* of syrup of orange peel, to be mixed, and triturated into a uniform pulp.

The preparation of the United States Pharmacopœia contains cinnamon, ginger, cardamom, and nutmeg, without carbonate of lime, which appears to us to be an unnecessary if not improper ingredient; as it is not always indicated in cases which call for the use of the confection, and may be added extemporaneously when required. The aromatic confection affords a convenient method of administering the spices which enter into its composition, and an agreeable vehicle for other medicines. It is given in debilitated states of the stomach, alone or as an adjuvant to other substances. The dose is from ten to sixty grains.

Off. Prep. Pilulæ Digitalis et Scillæ. *Ed.*

W.

CONFECTIO AURANTII CORTICIS. *U. S.* CONFECTIO AURANTII. *Lond.* CONSERVA AURANTII. *Ed.* *Confection of Orange Peel.*

"Take of Fresh Orange Peel, separated from the fruit by grating, *a pound; Sugar [refined] three pounds.* Beat the Orange Peel with the Sugar gradually added, till they are thoroughly mixed." *U. S.*

The directions of the *London* and *Edinburgh Colleges* correspond with the above. The rind of the bitter orange is intended by these Colleges, that either of the bitter or sweet, by the *U. S. Pharmacopœia*. By the *London* process, the beating is performed in a stone mortar with a wooden pestle.

This confection is sometimes used as a grateful aromatic vehicle or adjunct of tonic and purgative powders.

W.

CONFECTIO CASSIÆ. *Lond.* ELECTUARIUM CASSIÆ. *Dub.* *Confection of Cassia.*

"Take of Cassia [pulp] *half a pound; Manna two ounces; Tamarind [pulp] an ounce; Syrup of Roses eight fluid ounces.* Bruise the Manna, and dissolve it in the Syrup; then mix in the Cassia and Tamarind [pulp], and evaporate to a proper consistence." *Lond.*

The formula of the *Dublin College* corresponds with that of the *London*, except that syrup of orange peel is substituted for the syrup of roses.

The confection of cassia is slightly laxative; but is seldom if ever prepared in this country, and might very properly be expunged from the catalogue of Preparations, as it is both feeble and expensive.

W.

ELECTUARIUM CATECHU. *Ed.* ELECTUARIUM CATECHU COMPOSITUM. *Dub.* *Electuary of Catechu.*

"Take of Catechu and Kino, of each, *four ounces; Cinnamon and Nut-*

meg, of each, *one ounce*; Opium, diffused in a little Sherry, *one drachm and a half*; Syrup of Red Roses, reduced to the consistence of honey, *one pint and a half* [Imperial measure]. Pulverize the solids, mix the opium and syrup, then the powders, and beat them thoroughly into a uniform mass." *Ed.*

"Take of Catechu *four ounces*; Cinnamon Bark *two ounces*; Kino *three ounces*. Rub these to powder, and add of Turkey Opium, diffused in Spanish White Wine, *a drachm and a half*; Syrup of Ginger, evaporated to the consistence of honey, *two pounds and a quarter*. Mix them." *Dub.*

These preparations do not essentially differ. They are aromatic and astringent, containing one grain of opium in about two hundred grains of the mass; and may be advantageously given in diarrhœa and chronic dysentery, in the dose of half a drachm or a drachm more or less frequently repeated. They may be taken in the form of bolus, or diffused in water. *W.*

CONFECTIO OPII *U. S., Lond., Dub.* ELECTUARIUM OPII. *Ed. Confection of Opium.*

"Take of Opium, in powder, *four drachms and a half*; Aromatic Powder *six ounces*; Clarified Honey *fourteen ounces*. Rub the Opium with the Aromatic Powder; then add the Honey, and beat them together until thoroughly mixed." *U. S.*

"Take of Opium, in powder, *six drachms*; Long Pepper *an ounce*; Ginger *two ounces*; Caraway *three ounces*; Tragacanth, in powder, *two drachms*; Syrup *sixteen fluidounces* [Imperial measure]. Rub them together to a very fine powder, and keep them in a covered vessel. But when the Confection is to be used, add *sixteen fluidounces* of Syrup previously heated, and mix." *Lond.*

The *Dublin College* takes the same dry materials, and in the same quantities as the *London*; but first rubs the opium with *a pound* of heated syrup, and then mixes with these the remaining articles reduced to powder.

"Take of Aromatic Powder, *six ounces*; Senega in fine powder, *three ounces*; Opium, diffused in a little Sherry, *half an ounce*; Syrup of Ginger *a pound*. Mix them together, and beat them into an electuary." *Ed.*

This confection was intended as a substitute for those exceedingly complex and unscientific preparations which were formerly known by the names of *theriaca* and *mithridate*, and which have been expelled from modern pharmacy. The *seneka*, directed in the last edition of the *Edinburgh Pharmacopœia*, was probably put inadvertently for *serpentaria* directed in the old Latin edition. The former medicine has no property which adapts it to this position. The preparation is a combination of opium with spices, which render it more stimulant, and more grateful to a debilitated stomach. It is given in atonic gout, flatulent colic, diarrhœa unattended with inflammation, and in various other diseases requiring the use of a stimulant narcotic. Added to Peruvian bark or sulphate of quinia it increases considerably the efficacy of this remedy in obstinate cases of intermittent fever. One grain of opium is contained in about thirty-six grains of the *U. S.* and *London* confections, in twenty-five grains of the *Dublin*, and in forty-three of the *Edinburgh*. *W.*

CONFECTIO PIPERIS NIGRI. *Lond., Dub.* ELECTUARIUM PIPERIS. *Ed. Confection of Black Pepper.*

"Take of Black Pepper, Elecampare, each, *a pound*; Fennel [seeds] *three pounds*; Honey, Sugar [refined], each, *two pounds*. Rub the dry ingredients together into a very fine powder, and keep them in a covered vessel. But whenever the confection is to be used, add the Honey, and beat them until thoroughly incorporated." *Lond.*

The *Dublin College* takes the same materials, in the same proportions, and in like manner reduces them to powder; but completes the process by immediately incorporating the honey with the other ingredients. The *Edinburgh* process agrees with the *Dublin*, except in substituting powdered liquorice root for elecampane.

This preparation was intended as a substitute for *Ward's paste*, which acquired some reputation in Great Britain as a remedy in piles and ulcers of the rectum. To do good, it must be continued, according to Mr. Brodie, for two, three, or four months. The dose is from one to two drachms repeated two or three times a day. Its stimulating properties render it inapplicable to cases attended with much inflammation. W.

CONFECTIO ROSÆ. U. S. CONFECTIO ROSÆ GALLICÆ. Lond. CONSERVA ROSÆ. Ed., Dub. *Confection of Roses. Conserve of Roses.*

"Take of Red Roses, in powder, *four ounces*; Sugar [refined], in powder, *thirty ounces*; Clarified Honey *six ounces*; Rose Water *eight fluid ounces*. Rub the roses with the Rose Water at a boiling heat; then add gradually the Sugar and Honey, and beat them together until thoroughly mixed." U. S.

"Take of Red Roses [fresh] *a pound*; Sugar [refined] *three pounds*. Beat the Rose petals in a marble mortar; then add the Sugar, and beat again until they are incorporated." Lond.

The *Dublin* process is the same as the London. The *Edinburgh College* directs the petals to be beaten into a pulp with the gradual addition of twice their weight of white sugar.

In the British processes, the unblown petals only are used, and these should be deprived of their claws; in other words, the rose buds should be cut off a short distance above their base, and the lower portion rejected. In the last edition of the U. S. Pharmacopœia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex.

This confection is slightly astringent, but is almost exclusively used as a vehicle of other medicines, or to impart consistence to the pilular mass. The *Edinburgh College* employs it in most of their officinal pills.

Off. Prep. Pilulæ Hydrargyri, U. S., Lond., Ed., Dub. W.

CONFECTIO ROSÆ CANINÆ. Lond. CONSERVA ROSÆ FRUCTUS. Ed. *Confection of the Dog-rose.*

"Take of Dog-rose [pulp] *a pound*; Sugar [refined], in powder, *twenty ounces*. Expose the Pulp to a gentle heat in an earthen vessel; then add the Sugar gradually, and rub them together until they are thoroughly mixed." Lond.

"Take any convenient quantity of hips, carefully deprived of their carpels, beat them to a fine pulp, adding gradually thrice their weight of white Sugar." Ed.

This preparation is acidulous and refrigerant, and is used in Europe for forming more active medicines into pills and electuaries.

Off. Prep. Pilulæ Hydrargyri Iodidi. Lond. W.

CONFECTIO KUTÆ. Lond. CONSERVA RUTÆ. Dub. *Confection of Rue.*

"Take of dried Rue, Caraway, Laurel Berries, each, *an ounce and a half*; Sagapenum *half an ounce*; Black Pepper *two drachms*; Honey [clarified] *sixteen ounces*. Rub the dry ingredients together to a very fine powder, and preserve them. Then, as often as the confection is to be used, add the Honey, and mix the whole together." Lond.

The *Dublin* process differs only in the immediate addition of the honey to the other ingredients.

The confection of rue is antispasmodic, and in Great Britain is employed in the form of enema in hysterical complaints and flatulent colic; but in this country it is not used. From a scruple to a drachm may be administered, diffused in half a pint of warm mucilaginous fluid. W.

CONFECTIO SCAMMONII. *Lond.* ELECTUARIUM SCAMMONII. *Dub.* Confection of Scammony.

“Take of Scammony, in powder, *an ounce and a half*; Cloves, bruised, Ginger, in powder, each, *six drachms*; Oil of Caraway *half a fluidrachm*; Syrup of Roses *a sufficient quantity*. Rub the dry ingredients into a very fine powder, and keep them; then, when the Confection is to be used, pour in the Syrup, and again rub them; finally add the Oil of Caraway, and mix them all.” *Lond.*

The *Dublin College* employs the same materials in the same quantities, but immediately incorporates the syrup and oil with the dry ingredients.

This confection is actively cathartic in the dose of half a drachm or a drachm; but is very little used, and has been omitted in the last edition of the U. S. Pharmacopœia. The proportion of Scammony is uncertain, from the indefinite quantity of syrup employed. W.

CONFECTIO SENNÆ. *U.S., Lond.* ELECTUARIUM SENNÆ. *Ed., Dub.* Confection of Senna. *Lenitive Electuary.*

“Take of Senna *eight ounces*; Coriander [seed] *four ounces*; Liquorice Root, bruised, *three ounces*; Figs *a pound*; Pulp of Prunes, Pulp of Tamarinds, Pulp of Purging Cassia, each, *half a pound*; Sugar [refined] *two pounds and a half*; Water *four pints*. Rub the Senna and Coriander together, and separate ten ounces of the powder with a sieve. Boil the residue with the Figs and Liquorice Root, in the Water, to one-half; then press out the liquor and strain. Evaporate the strained liquor, by means of a water-bath, to a pint and a half; then add the Sugar and form a syrup. Lastly, rub the Pulps with the syrup gradually added, and, having thrown in the sifted powder, beat all together until thoroughly mixed.” *U.S.*

The *London* process corresponds with the above. The *Edinburgh College* directs *a pound* of the pulp of prunes, and omits the pulps of tamarinds and cassia fistula; but otherwise proceeds in the same manner. The *Dublin College* boils *a pound* of the pulp of prunes, and *two ounces* of the pulp of tamarinds, in *a pint and a half* of molasses, to the thickness of honey; then adds *four ounces* of senna in very fine powder, and, when the mixture cools, *two drachms* of oil of caraway; and, lastly, mixes the whole intimately.

The confection of senna, when properly made, is an elegant preparation. The pulp of purging cassia is most conveniently obtained by boiling the bruised pods in water, straining the decoction, and evaporating to the consistence of an electuary. The pulp of prunes may be prepared by boiling the fruit in a small quantity of water to soften it, then pressing it through a hair sieve, and evaporating to a proper consistence. The tamarinds, when too dry for immediate use, may be treated in the same manner. In each case, the evaporation should be completed by means of a water-bath, in order to prevent the pulps from being burnt. It is common to omit the cassia pulp in the preparation of the confection, as the pods are not always to be found in the market. But as this is next to senna the most active ingredient, the omission is to be regretted; and there is no doubt that a steady

demand for the fruit would be met by an abundant supply from the West Indies.

This is one of our best and most pleasant laxatives, being admirably adapted to cases of habitual costiveness, especially in pregnant women and persons affected with piles. It is also very useful in the constipation which is apt to attend convalescence from fevers and other acute diseases. The mean dose is two drachms, to be taken at bed-time.

W.

CUPRUM.

Preparations of Copper.

CUPRI SUBACETAS PRÆPARATUM. *Dub. Prepared Subacetate of Copper.*

“Let the Subacetate of Copper be ground to powder, and the finer parts separated in the manner directed for the preparation of Chalk.” *Dub.*

The object of this process is, by levigation and elutriation, to reduce verdigris to the state of a very fine powder. A chemical change is at the same time produced, which was not originally contemplated. The diacetate of copper which it contains, consisting of one equivalent of acid, two equiv. of protoxide, and six of water, is converted by the action of water into a soluble acetate and an insoluble trisacetate. The latter, consisting of one equiv. of acetic acid, three equiv. of protoxide of copper, and one and a half of water, is the Dublin *prepared subacetate of copper*, which, therefore, differs from commercial verdigris in composition as well as in its state of aggregation. (See *Cupri Acetas*.) This preparation is used only as an escharotic and stimulant application to unhealthy ulcers and obstinate cutaneous eruptions.

Off. Prep. Oxymel Cupri Subacetatis, *Dub.*; Unguentum Cupri Subacetatis, *Dub.*

W.

CUPRUM AMMONIATUM. *U. S., Ed., Dub.* CUPRI AMMONIO-SULPHAS. *Lond. Ammoniated Copper.*

“Take of Sulphate of Copper *half an ounce*; Carbonate of Ammonia *six drachms*. Rub them together in a glass mortar till the effervescence ceases; then wrap the Ammoniated Copper in bibulous paper, and dry it with a gentle heat. Let it be kept in a well stopped glass bottle.” *U. S.*

The processes of the British Colleges are essentially the same as the above, the ingredients, proportions, and general mode of operating being identical. The *London College* orders that the salt be dried in the air, and omits the direction as to the mode of keeping it; the *Edinburgh* directs that the product should be first dried in folds of blotting paper, and afterwards by exposure for a short time to the air; and the *Dublin* orders the ingredients to be triturated in an earthenware mortar.

When the two salts above mentioned are rubbed together, a reaction takes place between them, attended with the extrication of the water of crystallization of the sulphate of copper, which renders the mass moist, and the simultaneous escape of carbonic acid gas from the carbonate (sesquicarbonate) of ammonia, which occasions an effervescence. The colour is at the same time altered, passing from the light blue of the powdered sulphate of copper to a beautiful deep azure. The nature of the chemical changes which take place is not precisely known. One of the views which have been taken is, that the blue vitriol parts with a portion of its acid to the ammonia of the carbonate, thus forming a subsulphate of copper and sulphate of ammonia,

which are either mixed together, or chemically united in the form of a double salt, the sulphate of copper and ammonia. According to Phillips, the sulphuric acid of the sulphate of copper unites with the ammonia of a portion of the sesquicarbonate of ammonia; while the carbonic acid of the decomposed sesquicarbonate partly escapes, and partly combines with the oxide of copper; so that the resulting preparation consists of sulphate of ammonia, carbonate of copper, and undecomposed sesquicarbonate of ammonia. It is highly probable that the Cuprum Ammoniatum, independently of the excess of sesquicarbonate of ammonia which it may contain, is identical with the crystallized salt obtained by dropping a solution of pure ammonia into a solution of sulphate of copper till the subsalt first thrown down is dissolved, then concentrating, and precipitating by alcohol. Now, from the analysis of this salt by Berzelius, it appears to contain one equivalent of sulphuric acid, one of oxide of copper, two of ammonia, and one of water, which may be supposed to be combined in the form of a double salt—the *cupro-sulphate of ammonia*—consisting of one equiv. of sulphate of ammonia, one of cuprate of ammonia in which the oxide of copper acts the part of an acid, and one of water of crystallization ($\text{NH}_3 + \text{SO}_3$) $+(\text{NH}_3 + \text{CuO}) + \text{HO}$. But as half an ounce of sulphate of copper would require for such a result somewhat less than the same weight of sesquicarbonate of ammonia, there must be a considerable excess of the latter salt, unless dissipated in the drying process. In the uncertainty which exists as to the precise nature of the preparation, the name of *ammoniated copper* appears to be as appropriate for a pharmaceutical title as any that could be adopted.

This salt has a beautiful deep azure-blue colour, a strong ammoniacal odour, and a styptic, metallic taste. It is soluble in water, and the solution has an alkaline reaction on vegetable colours; but, unless there be an excess of sesquicarbonate of ammonia, the solution deposits subsulphate of copper if much diluted. When exposed to the air it parts with ammonia, and is said to be ultimately converted into sulphate of ammonia and carbonate of copper. This change is apt to occur to a greater or less extent while it is drying. It should not, therefore, be prepared in large quantities at a time, and should be kept in well-closed bottles. By heat, the whole of it is dissipated, except the oxide of copper. Arsenious acid precipitates a green arsenite of copper from its solution. Potassa, soda, lime-water, and the acids are incompatible with it.

Medical Properties and Uses. Ammoniated copper is tonic, and is thought to exercise an influence over the nervous system which renders it antispasmodic. It has been much employed in epilepsy, in which it was recommended by Cullen. There is good reason to believe that it has occasionally effected cures; but like all other remedies in that complaint it very frequently fails. It has also been used in chorea, hysteria, and worms; and by Swediaur as an injection in gonorrhœa and leucorrhœa. In over-doses it produces vomiting, and the poisonous effects which result from the other preparations of copper. (See *Cuprum*.) It is said, however, to be less apt to excite nausea. The dose is a quarter or half a grain, repeated twice a day, and gradually increased to four or five grains. It may be given in pill or solution. The medicine should not be very long continued without interruption; according to Cullen, not longer than a month.

Off. Prep. Cupri Ammoniaci Aqua, *Dub., Lond.*; Pilulæ Cupri Ammoniaci, *Ed.*

W.

CUPRI AMMONIATI AQUA. *Dub.* LIQUOR CUPRI AMMONIO-SULPHATIS. *Lond.* CUPRI AMMONIATI SOLUTIO. *Ed.* *Solution of Ammoniated Copper.*

“Take of Ammonio-sulphate of Copper *a drachm*; Distilled Water *a pint* [Imperial measure]. Dissolve the Ammonio-sulphate of Copper in the Water, and filter.” *Lond.*

The *Edinburgh* formula is the same as the *London*. The *Dublin College* employs *one part* of the salt to *one hundred parts* of distilled water.

By the quantity of water employed in these processes, the ammoniated copper, unless it contain an excess of carbonate of ammonia, which it probably does when recently prepared, is said by Mr. Phillips to be decomposed, with a precipitation of one-half of the oxide of copper. According to the same author, a smaller portion of water dissolves it perfectly.

This solution is sometimes employed as a stimulant to foul and indolent ulcers, and, diluted with water, as an application to the cornea when affected with specks or opacity; but it is probably in no respect superior for these purposes to a solution of sulphate of copper, and scarcely deserves a place among the official preparations.

W.

DECOCTA.

Decoctions.

Decoctions are solutions of vegetable principles, obtained by boiling the substances containing these principles in water. Vegetables generally yield their soluble ingredients more readily and in larger proportion to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapour over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a general rule, be long continued; as the ingredients of the vegetable are apt to react on each other, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction, should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fibre.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavourable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble or but slightly soluble in cool water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process, more matter is often dissolved than the water can retain in solution, so that upon cooling a precipitation takes place, and the liquid is rendered turbid. When the active principle is thus dissolved in excess, the decoction should always be strained while hot; so that the matter which separates on cooling, may be mixed again with the fluid by agitation at the time of administering the remedy.

In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should any one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a general rule, glass or earthenware vessels should be preferred; as those made of metal are sometimes corroded by the ingredients of the decoction, which thus becomes contaminated. Vessels of clean cast-iron or of common tin are preferable to those of copper, brass, or zinc; but iron pots should not be used when astringent vegetables are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, in warm weather, for a longer period than forty-eight hours. W.

DECOCTUM ALOES COMPOSITUM. *Lond., Dub.* **DECOCTUM ALOËS,** *Ed.* *Compound Decoction of Aloes.*

“Take of Extract of Liquorice *half an ounce*; Carbonate of Potassa *two scruples*; Hepatic Aloes in powder, Myrrh in powder, Saffron, each, *a drachm*; Water *a pint*. Boil together to twelve ounces, and strain; then add *four fluidounces* of Compound Tincture of Cardamom.” *Dub.*

The *Edinburgh* process may be considered as identical with the *Dublin*, except that a choice is allowed between the socotrine and hepatic aloes.

“Take of Extract of Liquorice *seven drachms*; Carbonate of Potassa *a drachm*; Aloes in powder, Myrrh in powder, Saffron, each, *a drachm and a half*; Compound Tincture of Cardamom *seven fluidounces*; Distilled Water *a pint and a half* [Imperial measure]. Boil the liquorice, Carbonate of Potassa, Aloes, Myrrh, and Saffron with the Water to a pint, and strain; then add the Compound Tincture of Cardamom.” *Lond.*

There is no essential difference between the two processes. That of the *Dublin College* is preferable for practical purposes in this country, as the measures correspond with our own; while those of the *London and Edinburgh Colleges*, adopted at the last revision of their Pharmacopœias, being divisions of the British Imperial gallon, are wholly inapplicable here.

The effect of the alkaline carbonate is, by combining with the resinous ingredient (apotheme of *Berzelius*) of the aloes, to render it more soluble in water, while the liquorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition.

Long boiling impairs the purgative property of aloes; and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation, and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself, and not so liable to produce or aggravate hemorrhoidal disease. At the same time it is more tonic and cordial from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the carbonate of potassa. It is given as a gentle cathartic, tonic, and emmenagogue; and is especially useful in dyspepsia, habitual constipation, and those complicated cases in which suppressed or retained menstruation is connected with enfeebled digestion and a languid state of bowels. The dose is from half a fluidounce to two fluidounces.

It should not be combined in prescription with acids, acidulous salts, or other saline bodies which are incompatible with the alkaline carbonate employed in its preparation. W.

DECOCTUM ALTHÆÆ. *Dub.* MISTURA ALTHÆÆ. *Ed.* *Decoction of Marsh Mallow.*

"Take of the Herb and Root of Marsh Mallow, dried and bruised, *four ounces*; Raisins, stoned, *two ounces*; Water *seven pints*. Boil down to five pints, and strain the liquor; then set it by till the dregs have subsided, and decant." *Dub.*

The *Edinburgh College* takes *four ounces* of the root, *two ounces* of the raisins, and *five pints* [Imperial measure] of boiling water, and proceeds as above, boiling down to three pints.

This decoction is a simple mucilage flavoured with raisins; and may be used advantageously as a drink, in all cases in which demulcents are indicated.

W.

DECOCTUM CETRARIÆ. *U.S., Lond.* DECOCTUM LICHENIS ISLANDICI. *Dub.* *Decoction of Iceland Moss.*

"Take of Iceland Moss *half an ounce*; Water *a pint and a half*. Boil down to a pint, and strain with compression." *U.S.*

The *London College* orders *five drachms* of the moss with *a pint and a half* of water to be boiled to a pint and strained; but, as the Imperial measure is used in the process, the proportion is in fact equivalent to about half an ounce to the apothecaries' pint. By the *Dublin* process, *half an ounce* of the moss is digested for two hours in a close vessel with *a pint* of boiling water, then boiled for fifteen minutes, and the liquor strained while hot.

As the bitter principle is dissolved along with the starch of the lichen, this decoction unites an unpleasant flavour to its demulcent properties; but the plan which has been proposed of first extracting the bitterness by maceration in water, or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, is inadmissible; as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. (See *Cetraria*.) A pint of the decoction may be taken in divided doses during the twenty-four hours.

W.

DECOCTUM CHAMÆMELI COMPOSITUM. *Dub.* *Decoction of Chamomile.*

"Take of dried Chamomile Flowers *half an ounce*; Fennel Seeds *two drachms*; Water *a pint*. Boil for a short time, and strain." *Dub.*

In preparing this decoction, the aromatic should not be added till near the end of the process. The decoction contains the bitter extractive of the chamomile, with little of its peculiar aroma, which is dissipated by the boiling. It is inferior, therefore, for internal use, to the infusion; and is calculated only for fomentations and enemata.

W.

DECOCTUM CHIMAPHILÆ. *U.S., Lond.* DECOCTUM PYROLÆ. *Dub.* *Decoction of Pipsissewa. Decoction of Winter Green.*

"Take of Pipsissewa, bruised, *an ounce*; Water *a pint and a half*. Boil down to a pint, and strain." *U.S.*

"Take of Pipsissewa *an ounce*; Distilled Water *a pint and a half* [Imperial measure]. Boil to a pint, and strain." *Lond.*

"Take of Pipsissewa *an ounce*; Water *two pints*. Macerate for six hours; then take out the Pipsissewa, and having bruised it, return it to the liquor, and evaporate until enough remains to afford one pint of decoction strained with expression." *Dub.*

The previous maceration directed by the *Dublin College* is quite superfluous, especially in relation to the fresh leaves, which may almost always

be obtained in this country. The medical properties and uses of pipsissewa have been detailed under the head of Chimaphila. One pint of the decoction may be given in the course of twenty-four hours. W.

DECOCTUM CINCHONÆ. *U. S., Ed., Dub.* DECOCTUM CINCHONÆ CORDIFOLIÆ. DECOCTUM CINCHONÆ LANCIFOLIÆ. DECOCTUM CINCHONÆ OBLONGIFOLIÆ. *Lond. Decoction of Peruvian Bark.*

“Take of Peruvian Bark, bruised, *an ounce*; Water *a pint*. Boil for ten minutes in a covered vessel, and strain the liquor while hot.” *U. S.*

The *London College* directs separate decoctions of the three varieties of bark, but in each case employs the same proportions and proceeds in the same way. Their process is essentially the same as ours. The *Edinburgh College* takes *an ounce* of either of its officinal varieties of bark, and *twenty-four fluidounces* [Imperial measure] of water, boils for ten minutes, allows the decoction to cool, then filters it, and evaporates to sixteen fluidounces. The *Dublin College*, without specifying the length of boiling, orders *an ounce* of the pale bark, in coarse powder, and enough water to yield *a pint* of the strained decoction.

When the physician directs the decoction according to the *U. S.* formula, he should specify the variety of bark he wishes to be employed.

The virtues of Peruvian bark, though extracted more rapidly by decoction than by infusion, are materially impaired by long boiling, in consequence of the changes effected in its constituents, either by their mutual reaction, or by the agency of atmospheric oxygen, or by both causes united. To prevent this result, the process is directed to be performed in a covered vessel, and to be continued only ten minutes. But even with these precautions a considerable precipitate takes place in the decoction upon cooling, which is thus rendered turbid. According to Pelletier, besides the kinates of cinchonia and quinia, the water dissolves gum, starch, yellow colouring matter, kinate of lime, tannin, and a portion of cinchonic red, with a minute quantity of fatty matter. But the tannin and starch, at the boiling temperature, unite to form a compound insoluble in cold water; and, when the decoction is allowed to cool, this compound is precipitated, together with a portion of the cinchonic red and fatty matter, which carry with them also a considerable quantity of the alkaline principle of the bark. (*Journ. de Pharm.* vii. 119.) Hence the decoction is ordered to be strained while hot, so that the portion of active matter precipitated may be mingled by agitation with the liquor, and not be lost. Pelletier recommends that a larger proportion of water, sufficient to retain the alkali in solution, be employed, that the decoction be filtered when cold, and then sufficiently concentrated by evaporation. This plan has been adopted by the *Edinburgh College*, but is unnecessarily tedious. A better mode is to add to the liquid some acid which may form with the quinia and cinchonia compounds more soluble than the native salts. Lemon juice has been long employed as a useful addition to the decoction of cinchona, and we can now understand the manner in which it acts. Sulphuric acid in excess answers the same purpose. By acidulating the pint of water employed in preparing the decoction with a fluidrachm of the aromatic or diluted sulphuric acid, we shall probably enable the menstruum to extract all the virtues of the bark. The propriety of such an addition is confirmed by the experiments of *MM. Henry, Jun.,* and *Plisson*, who have ascertained that portions of the alkalies exist in the bark connected with the colouring matter in the form of insoluble compounds, and that it is impossible, therefore, completely to exhaust the bark by water alone. There may, however, be some diversity of action in the different salts of

quinia and cinchonia; and the native kinates may under certain circumstances be most efficient.

Numerous substances produce precipitates with this decoction; but comparatively few affect its activity as a medicine. (See *Infusum Cinchonæ*.) Tannic, gallic, oxalic, and tartaric acids, and the substances containing them, should be excluded from the decoction; as they form salts with the alkaline principles of the bark, which are either insoluble or but slightly soluble in water. The alkalies, alkaline earths, and salifiable bases generally, should also be excluded, because, uniting with the kinic acid, they precipitate the quinia and cinchonia.

The dose of the decoction is two fluidounces, to be repeated more or less frequently according to circumstances. Two drachms of orange peel added to the decoction while still boiling hot, improve its flavour, and render it more agreeable to the stomach. W.

DECOCTUM CORNÛS FLORIDÆ. *U. S. Decoction of Dogwood.*

"Take of Dogwood [bark], bruised, *an ounce*; Water *a pint*. Boil for ten minutes in a covered vessel, and strain the liquor while hot." *U. S.*

This decoction has been proposed as a substitute for that of Peruvian bark; but, though possessed of analogous properties, it is much inferior in efficacy, and is not likely to be extensively employed so long as the Peruvian tonic is attainable. The dose is two fluidounces. W.

DECOCTUM CYDONIÆ. *Lond. Decoction of Quince Seeds.*

"Take of Quince [seeds] *two drachms*; Distilled Water *a pint* [Imperial measure]. Boil over a slow fire for ten minutes; then strain." *Lond.*

This decoction is viscid, nearly colourless, insipid, and inodorous; and consists chiefly of the mucilaginous principle of the quince seeds dissolved in water. For an account of the properties and uses of this mucilage, see *Cydonia*. It is only employed externally. As it speedily undergoes decomposition, it should be used immediately after being prepared. W.

DECOCTUM DULCAMARÆ. *U. S., Lond., Ed., Dub. Decoction of Bittersweet.*

"Take of Bittersweet, bruised, *an ounce*; Water *a pint and a half*. Boil down to a pint, and strain." *U. S.*

The processes of the British Colleges correspond with the above.

The slender twigs of the bittersweet are the part employed. Their properties and uses have been already detailed under the head of *Dulcamara*. The dose of the decoction is from one to two fluidounces three or four times a day. W.

DECOCTUM GEOFFROYÆ. *Dub. Decoction of Cabbage-tree Bark.*

"Take of Cabbage-tree Bark, bruised, *an ounce*; Water *two pints*. Boil down to a pint, and to the strained liquor add *two ounces* of the Syrup of Orange Peel." *Dub.*

This decoction has the colour of Madeira wine. It is powerfully anthelmintic, and is a popular remedy in the West Indies. The disagreeable effects which are said to arise from an over-dose, or from drinking cold water during its operation, may be counteracted, according to Dr. Wright, by washing out the stomach with warm water, purging with castor oil, and administering lemonade freely. The dose for an adult is two fluidounces, for a child two or three years old, half a fluidounce, to be gradually increased at each successive administration till it produces nausea. W.

DECOCTUM GLYCYRRHIZÆ. *Dub. Decoction of Liquorice Root.*

“Take of Liquorice Root, bruised, *an ounce and a half*; Water *a pint*. Boil for ten minutes, and strain.” *Dub.*

This decoction may be used as a demulcent beverage, or as a vehicle for medicines of unpleasant flavour.

DECOCTUM GRANATI. *Lond. Decoction of Pomegranate.*

“Take of Pomegranate [rind] *two ounces*; Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint, and strain.” *Lond.*

The dose of this decoction is a fluidounce. For its uses see *Granatum*.

DECOCTUM GUAIACI COMPOSITUM. *Dub. DECOCTUM GUAIACI. Ed. Compound Decoction of Guaiacum Wood.*

“Take of Guaiac turnings *three ounces*; Raisins *two ounces*; Sassafras [root] rasped, and Liquorice Root bruised, each, *one ounce*; Water *eight pints* [Imperial measure]. Boil the Guaiac and Raisins gently with the Water down to five pints, adding the Liquorice and Sassafras towards the end. Strain the decoction.” *Ed.*

“Take of Guaiacum Wood, rasped, *three ounces*; Sassafras root, sliced, *ten drachms*; Liquorice Root, bruised, *two ounces and a half*; Water *ten pints*. Boil the Guaiacum Wood in the Water down to one-half; near the end of the boiling add the Liquorice and Sassafras, and strain the liquor.” *Dub.*

This is the old *decoction of the woods*. Notwithstanding its former reputation, it is little more than a demulcent drink; for water is capable of dissolving but a minute proportion of the active matter of guaiacum wood, and one ounce of sassafras root can impart no appreciable activity to five pints of menstruum. It was thought useful in chronic rheumatism and cutaneous affections, and as an adjuvant to a mercurial course in syphilis, or an alterative course of antimonials. As the patient was directed to be kept warm during its use, it no doubt acted favourably in some instances as a mere diluent, by promoting perspiration. From one to two pints may be taken in the course of the day, in doses of about four fluidounces. *W.*

DECOCTUM HÆMATOXYLI. *U. S., Ed. Decoction of Logwood.*

“Take of Logwood, rasped, *an ounce*; Water *two pints*. Boil down to a pint, and strain.” *U. S.*

“Take of Logwood, in chips, *one ounce*; Water *a pint* [Imperial measure]; Cinnamon, *one drachm*, in powder. Boil the Logwood in the Water down to ten fluidounces, adding the Cinnamon towards the end; and then strain.” *Ed.*

This is an excellent astringent in diarrhœa; particularly in that form of it which succeeds the cholera infantum of this climate, or occurs as an original complaint in children during summer. The dose for an adult is two fluidounces, for a child about two years old, two or three fluidrachms, repeated several times a day. A little bruised cinnamon may often be added with advantage at the end of the boiling, as directed by the Edinburgh College.

W.

DECOCTUM HORDEI. *U. S., Lond., Dub. Decoction of Barley.*

“Take of [Pearl] Barley *two ounces*; Water *four pints and a half*. First wash away, with cold water, the extraneous matters which adhere to the Barley; then pour upon it half a pint of the Water, and boil for a short

time. Having thrown away this water, pour the remainder boiling hot upon the Barley; then boil down to two pints, and strain." *U. S.*

The processes of the *British Colleges* do not essentially differ from the above.

Barley water, as this decoction is usually called, is much employed as a nutritive drink in febrile and inflammatory complaints, and, from the total absence of irritating properties, is peculiarly adapted to cases in which the gastric or intestinal mucous membrane is inflamed. As the stomach of those for whom it is directed is often exceedingly delicate, and apt to revolt against any thing having the slightest unpleasantness of flavour, it is important that the decoction should be properly made; and, though the office of preparing it generally falls to nurses, yet the introduction of the process into the *Pharmacopœia* is not without advantage, as a formula is thus ever before the physician, by which he may give his directions, with the certainty, if obeyed, of having a good preparation. The use of the washing with cold water, and of the first short boiling, is completely to remove any mustiness, or other disagreeable flavour, which the barley may have acquired from exposure.

Off. Prep. Enema Aloës, *Lond.*; Enema Terebinthinæ, *Lond.* W.

DECOCTUM HORDEI COMPOSITUM. *Lond., Dub.* MISTURA HORDEI. *Ed.* *Compound Decoction of Barley.*

"Take of Decoction of Barley *two pints* [Imperial measure]; Figs, sliced, *two ounces and a half*; Liquorice [root], sliced and bruised, *five drachms*; Raisins [stoned] *two ounces and a half*; Water a *pint* [Imperial measure]. Boil down to two pints [Imp. meas.], and strain." *Lond.*

"Take of Pearl-Barley, Figs sliced, Raisins freed of the seeds, of each, *two ounces and a half*; Liquorice Root, sliced and bruised, *five drachms*; Water *five pints and a half* [Imperial measure]. Clean the Barley, if necessary, by washing it with cold water; boil it with four pints and a half of the Water down to two pints; add the Figs, Raisins, and Liquorice Root, with the remaining pint of water; and again boil down to two pints; then strain." *Ed.*

"Take of Decoction of Barley *four pints*; Raisins stoned, Figs sliced, each, *two ounces*; Liquorice Root, sliced and bruised, *half an ounce*. During the boiling, add first the Raisins, then the Figs, and lastly the Liquorice Root a short time before it is finished, when the strained decoction ought to measure two pints." *Dub.*

The compound decoction of barley, in addition to the demulcent and nutritive properties of the simple, is somewhat laxative, and may be preferably employed where there is a tendency to constipation. But it is so often necessary to vary the nature of the sapid ingredients to suit the taste of the patient, that it would be better to leave the preparation entirely to extemporaneous prescription. W.

DECOCTUM MALVÆ COMPOSITUM. *Lond.* *Compound Decoction of Mallows.*

"Take of dried Mallows *an ounce*; dried Chamomile Flowers *half an ounce*; Water a *pint* [Imperial measure]. Boil for a quarter of an hour, and strain." *Lond.*

This is intended only for fomentations and enemata.

DECOCTUM MEZEREI. *Ed., Dub.* *Decoction of Mezereon.*

"Take of Mezereon, in chips, *two drachms*; Liquorice-root, bruised, *half an ounce*; Water *two pints* [Imperial measure]. Mix them and boil down with a gentle heat to a pint and a half, and then strain." *Ed.*

The *Dublin* process is essentially the same as the above.

This preparation affords a convenient mode of exhibiting mezereum, the acrimony of which is qualified by the demulcent principles of the liquorice root. For an account of its medical applications, see *Mezereum*. The dose is from four to eight fluidounces four times a day. W.

DECOCTUM PAPAVERIS. *Lond., Ed., Dub. Decoction of Poppy.*

"Take of White Poppy Capsules, sliced, *four ounces*; Water *four pints* [Imperial measure]. Boil for a quarter of an hour, and strain." *Lond.*

The *Edinburgh* and *Dublin* processes differ from the above only in the proportion of water, which in the former is *three pints* [Imp. meas.], in the latter *two pints*.

This decoction is used as an anodyne fomentation in painful tumours and superficial cutaneous inflammation or excoriation. It is recommended not to reject the seeds, as their oil, suspended in the water by the mucilage of the capsules, adds to the emollient virtues of the preparation. W.

DECOCTUM QUERCÛS ALBÆ. *U.S. Decoction of White Oak Bark.* DECOCTUM QUERCÛS. *Lond., Ed., Dub. Decoction of Oak Bark.*

"Take of White Oak Bark, bruised, *an ounce*; Water *a pint and a half*. Boil down to a pint, and strain." *U. S.*

The *London* and *Edinburgh Colleges* take *ten drachms* of oak bark and *two pints* [Imperial measure] of distilled water, and boil to a pint; the *Dublin College*, *an ounce* of the bark and *two pints* [Apothecaries' measure] of water, and boils to a pint.

This decoction contains the tannin, extractive, and gallic acid of oak bark. It affords precipitates with the decoction of Peruvian Bark and other substances containing vegetable alkalies, with solution of gelatin, and with most metallic salts, particularly those of iron. Alkaline solutions diminish or destroy its astringency. Its uses have been already detailed. The dose is a wineglassful, frequently repeated. W.

DECOCTUM SARSAPARILLÆ. *Dub.* DECOCTUM SARZÆ. *Lond., Ed. Decoction of Sarsaparilla.*

"Take of Sarsaparilla, sliced, *five ounces*; Boiling Distilled Water *four pints* [Imperial measure]. Macerate for four hours in a covered vessel, near the fire, then take out the Sarsaparilla and bruise it. Put it again into the liquor, and macerate it in the same manner for two hours more, then boil down to two pints [Imp. meas.] and strain." *Lond.*

The *Dublin College* orders *four ounces* of the root, previously washed, and *four pints* of boiling water, and proceeds as directed by the *London College*, except that the second maceration is omitted.

"Take of Sarza, in chips, *five ounces*; Boiling Water, *four pints* [Imperial measure]. Digest the root in the Water for two hours at a temperature somewhat below ebullition, take out the root, bruise it, replace it, boil down to two pints [Imp. meas.], and then squeeze out the decoction and strain it." *Ed.*

There can be no occasion for the maceration directed by the *British Colleges*; as, if the root is sliced and well bruised, all its ingredients that are soluble in water may be extracted by a length of boiling sufficient to reduce the liquor to one-half. An idea was formerly entertained that the virtues of sarsaparilla resided in its secula, the extraction of which was, therefore, the main object of the decoction. Hence the long boiling ordered by the *Colleges*. But this opinion is now admitted to be erroneous. The

activity of the root is believed to depend upon one or more acrid principles, soluble to a certain extent in water cold or hot, and either volatilized, or rendered inert by chemical change at the temperature of 212° . This fact appears to be demonstrated by the experiments of Pope,* Hancock,† Soubeiran,‡ Beral, and others. Hancock makes the following observations. "After long boiling, the peculiar odour which rises abundantly on the coction of good *sarsa*, is almost extinguished. From the *sarsa* prepared in this way, I found no sensible results upon any patient, nor were its peculiar nauseating, drowsy, and racking effects produced by a large quantity, although the decoction of six or eight ounces was tried at a dose. These experiments having been carried to a sufficient length, most of the same patients recovered under the use of the *sarsa*, taken from the same parcels as before, but now prepared by simple maceration in hot water, *i. e.* affused in a boiling state, and kept near the boiling state for some hours. In all cases the *sarsa* was directed to be well bruised in large mortars, and in the mean time all other remedies were abstained from, which might, in any way, affect the result." Soubeiran macerated one portion of bruised *sarsaparilla* in cold water for twenty-four hours; infused another portion in boiling water, and digested with a moderate heat for two hours; boiled a third portion bruised, and a fourth unbruised, in water for two hours; and in each instance used the same relative quantities. Testing these various preparations by the taste, he found the cold and hot infusion scarcely different in this respect; and both possessed of a stronger odour and more acrid taste than the decoctions, of which that prepared with the bruised root was the strongest. Beral has proved that *sarsaparillin*, which is believed to be the active principle of the drug, is volatile. From all these facts the inference is obvious, that the best method of imparting the virtues of *sarsaparilla* to water is either by cold or hot infusion. Digestion for some hours in water maintained at a temperature of 180° or somewhat less, in a covered vessel, has strong testimony in its favour. Percolation in a displacement apparatus, if properly conducted, is a convenient, and no doubt efficient mode of exhausting the root, so far as water will effect that object. Decoction is the worst method; and the longer it is continued, the weaker will be the preparation. Accordingly, in the last edition of the U. S. Pharmacopœia, an infusion of *sarsaparilla* has been substituted for the simple decoction. It is probable that, as in the case of the Peruvian bark, a boiling of ten or fifteen minutes might be advantageously resorted to, when circumstances require the preparation to be made in less time than is requisite for infusion. In every instance the root should be thoroughly bruised, or reduced to a coarse powder, thus obviating the necessity for a long maceration, merely to overcome the cohesion of its fibres.

Precipitates are produced by various substances with the decoction of *sarsaparilla*; but it has not been ascertained how far such substances interfere with its activity. Those which merely throw down the fecula do not injure the preparation.

The simple decoction of *sarsaparilla* is chiefly used in the preparation of the compound decoction. If given alone, it may be administered in the dose of four or six fluidounces four times a day.

Off. Prep. Decoctum *Sarsaparillæ* Compositum. *Dub., Lond., Ed. W.*

* Trans. of the Medico-Chirurg. Society of London, vol. xii. p. 344.

† Trans. of the Medico-Botan. Society of London. See also Journ. of the Phil. Col. of Pharm. vol. i p. 295. The observations of Dr. Hancock are entitled to much credit, as he practised long in South America, in the neighbourhood of the best *sarsaparilla* regions.

‡ Journ. de Pharmacie, tom. xvi. p. 38.

DECOCTUM SARSAPARILLÆ COMPOSITUM. *U. S., Dub.*
 DECOCTUM SARZÆ COMPOSITUM. *Lond., Ed. Compound Decoction of Sarsaparilla.*

“Take of Sarsaparilla, sliced and bruised, *six ounces*; Bark of Sassafras Root, sliced, Guaiacum Wood, rasped, Liquorice Root, bruised, each, *an ounce*; Mezereon, sliced, *three drachms*; Water *four pints*. Boil for a quarter of an hour, and strain.” *U. S.*

“Take of Decoction of Sarsaparilla, boiling hot, *four pints* [Imperial measure]; Sassafras [root], sliced, Guaiacum Wood, rasped, Liquorice Root [fresh], bruised, each, *ten drachms*; Mezereon *three drachms*. Boil for a quarter of an hour, and strain.” *Lond.*

The *Edinburgh* process differs from the London only in the quantity of mezereon, which in the former is *half an ounce*. The *Dublin College* takes *four pints* of the decoction, *an ounce*, each, of sassafras, guaiacum wood, and liquorice root, and *three drachms* of mezereon, and proceeds as above.

The process of the *U. S. Pharmacopœia* differs essentially from the others in this respect, that, instead of taking the simple decoction of sarsaparilla prepared by long boiling, it mixes the bruised root immediately with the other ingredients, and boils the whole together for a few minutes. Thus the sarsaparilla does not undergo a longer boiling than the other substances; and the preparation is brought more nearly into accordance with the present state of knowledge in relation to this valuable drug. (See *Decoctum Sarsaparillæ*.) It might, perhaps, be a still farther improvement, if the ingredients were allowed, after the completion of the boiling, to remain in a covered vessel, in a warm place, with occasional agitation, for two or three hours before straining.

This decoction is an imitation of the celebrated *Lisbon diet drink*. The sarsaparilla and mezereon are the active ingredients; the guaiacum wood imparting scarcely any of its virtues, and the sassafras and liquorice serving little other purpose than to communicate a pleasant flavour.

If prepared with good sarsaparilla, and with a due regard to the practical rules which may now be considered as established, the decoction may be used with great advantage as a gentle diaphoretic and alterative in secondary syphilis, either alone, or as an adjuvant to a mercurial course; also in certain scrofulous and other depraved conditions of the system, in chronic rheumatism, and in various obstinate cutaneous affections. The dose is from four to six fluidounces three or four times a day. The patient during its use should wear flannel next the skin, and avoid unnecessary exposure to changes of temperature.*

W.

* The *Decoction of Zittman* (*Decoctum Zittmanni*) is a preparation of sarsaparilla much used in Germany, for similar purposes with our compound decoction of sarsaparilla; and, as it has attracted some attention in this country as a remedy in obstinate ulcerative affections, we give the formula of the Prussian Pharmacopœia, which is generally followed in its preparation: “Take of sarsaparilla *twelve ounces*; spring water *ninety pounds*. Digest for twenty-four hours; then introduce, enclosed in a small bag, *an ounce and a half* of saccharine alum (a paste formed of alum \mathfrak{zvi} , white lead \mathfrak{zvi} , sulphate of zinc \mathfrak{zij} , white sugar \mathfrak{ziss} , white of egg and distilled vinegar, each, *q. s.*), *half an ounce* of calomel, and *a drachm* of cinnabar. Boil to thirty pounds, and near the end of the boiling add of aniseed, fennel-seed, each, *half an ounce*, senna *three ounces*, liquorice root *an ounce and a half*. Put aside the liquor under the name of THE STRONG DECOCTION. To the residue add *six ounces* of sarsaparilla and *ninety pounds* of water. Boil to thirty pounds, and near the end add lemon-peel, cinnamon, cardamom, liquorice, of each, *three drachms*. Strain, and set aside the liquor under the name of THE WEAK DECOCTION. Mercury was detected by Wiggers in this decoction in very small proportion. It should not be prepared in metallic vessels, lest the mercurial in solution should be decomposed. The decoction may be drank freely.

DECOCTUM SCOPARII COMPOSITUM. *Lond.* DECOCTUM SCOPARII, *Ed.* *Compound Decoction of Broom.*

“Take of Broom, Juniper Fruit, Dandelion, each, *half an ounce*; Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint [Imperial measure], and strain.” *Lond.*

“Take of Broom-tops, and Juniper-tops, of each, *half an ounce*; Bitartrate of Potassa *two drachms and a half*; Water *a pint and a half* [Imperial measure]. Boil them together down to a pint [Imperial measure], and then strain.” *Ed.*

This decoction may be used as an adjuvant to more powerful diuretics in dropsy. From half a pint to a pint may be taken during the day. W.

DECOCTUM SENEGÆ. *U. S., Lond., Dub.* *Decoction of Seneka.*

“Take of Seneka, bruised, *an ounce*; Water *a pint and a half*. Boil down to a pint, and strain.” *U. S.*

The *London College* boils *ten drachms* of the root with *two pints* of distilled water to a pint; but the relation of the Imperial measure used by this College to the common wine measure is such, that the proportions in the decoction are essentially the same as those of the *U. S. Pharmacopœia*. The *Dublin College* directs *a pint and a half* of water to be boiled down with *three drachms* of the root to eight ounces.

It is customary to add to the seneka an equal weight of liquorice root, which serves to cover its taste, and in some measure to obtund its acrimony. The virtues and practical application of seneka have been already treated of. The dose of the decoction is about *two fluidounces* three or four times a day, or a tablespoonful every two or three hours. W.

DECOCTUM TARAXACI. *U. S., Ed., Dub.* *Decoction of Dandelion.*

“Take of Dandelion [root], bruised, *two ounces*; water *two pints*. Boil down to a pint, and strain.” *U. S.*

The *Edinburgh College* takes *seven ounces* of the fresh herb and root, and *two pints* [Imperial measure] of water, boils to one pint [Imperial measure], and strains. The *Dublin College* takes *four ounces* of the fresh herb and root, and *two pints* of water, boils to a pint, expresses, and strains.

This decoction is most efficient when prepared from the root alone. The dose is a wineglassful two or three times a day. (See *Taraxacum*.)

DECOCTUM TORMENTILLÆ. *Lond.* *Decoction of Tormentil.*

“Take of Tormentil, bruised, *two ounces*; Distilled water *a pint and a half* [Imperial measure]. Boil down to a pint, and strain.” *Lond.*

This decoction is astringent, and may be given in the dose of one or two fluidounces, three or four times a day. W.

DECOCTUM ULMI. *Lond., Dub.* *Decoction of Elm Bark.*

“Take of fresh Elm [bark], bruised, *two ounces and a half*; Distilled Water *two pints* [Imperial measure]. Boil down to a pint, and strain.” *Lond.*

The *Dublin College* orders *two ounces* of the bark and *two pints* of water to be reduced, by boiling, to a pint.

This decoction, being prepared from the bark of the European elm, is not used in this country. It had some repute in England as a remedy for

certain cutaneous disorders; but has fallen into discredit. From four to six fluidounces were given two or three times a day. W.

DECOCTUM UVÆ URSI. *U.S., Lond. Decoction of Uva Ursi.*

“Take of Uva Ursi *an ounce*; Water *twenty fluidounces*. Boil down to a pint, and strain.” *U. S.*

“Take of Uva Ursi, bruised, *an ounce*; Distilled Water *a pint and a half* [Imperial measure]. Boil down to a pint, and strain.” *Lond.*

This decoction contains the tannin, extractive, and gallic acid of the leaves. For an account of its uses see *Uva Ursi*. The dose is from one to two fluidounces three or four times a day. W.

DECOCTUM VERATRI. *Lond., Dub. Decoction of White Hellebore.*

“Take of White Hellebore, in powder, *ten drachms*; Distilled Water *two pints* [Imperial measure]; Rectified Spirit *three fluidounces*. Boil the White Hellebore with the Water to a pint, and when it has cooled, add the Spirit, express, and strain.” *Lond.*

The *Dublin* process corresponds with the above.

The root of the white hellebore imparts its acid properties to boiling water, and the decoction is powerfully cathartic and emetic; but, in consequence of the harshness of its action, it is not used internally. As an external application it is employed in psora, tinea capitis, lepra, and other cutaneous eruptions, in which it sometimes proves highly beneficial. When the skin is very irritable, it should be diluted with an equal measure of water. Even externally applied it should be used with some caution; as the veratria, upon which its activity depends, may possibly be absorbed. As the plant is not a native of this country, the *Veratrum viride*, which is similar in medical properties, may be advantageously substituted for it in the preparation of the decoction. W.

EMPLASTRA.

Plasters.

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Most of them have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the United States Pharmacopœia. Those plasters which contain none of the compound of oil and litharge, owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and oleaginous matter. Only two of this class have gained admission into our national Pharmacopœia; several of those directed by the British Colleges having been rejected as superfluous, and the Emplastrum Cantharidis transferred to the Cerates, to which class it properly belongs.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in a greater or less degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change colour and to become hard and

brittle; and as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be as much as possible excluded. The defect may usually be remedied by melting the plaster with a moderate heat, and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheep skin. A margin about a quarter or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper, so cut as to leave in the centre a vacant space of the required dimensions, and removing the paper when no longer required. The same object may sometimes be accomplished by employing two narrow rulers of sheet tin, graduated in inches, and so shaped that each of them may form two sides of a rectangle. (See the figure, p. 765.) These may be applied in such a manner as to enclose with them any given rectangular space, and may be fixed by weights upon the leather while the plaster is spread. For any other shape, as in the instance of plasters for the breast, pieces of tin may be employed having a vacuity within, corresponding to the required outline. The spreading of the plaster is most conveniently accomplished by means of a peculiar iron instrument employed for the purpose; though a common spatula will answer. This may be heated by means of a spirit lamp. A sufficient portion of the plaster should first be melted by the heated instrument, and having been received on a piece of coarse stiff paper, should, when nearly cool, be transferred to the leather, and applied evenly over its extended surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. When linen or muslin is used, and the dimensions of the portion to be spread are large, as is often the case with adhesive plaster, the best plan is to pass the cloth "on which the plaster has been laid, through a machine formed of a spatula fixed by screws, at a proper distance from a plate of polished steel." W.

EMPLASTRUM AMMONIACI. *U.S., Lond., Ed., Dub. Ammoniac Plaster.*

"Take of Ammoniac *five ounces*; Vinegar *half a pint*. Dissolve the Ammoniac in the Vinegar, and strain; then evaporate the solution by means of a water-bath, stirring constantly until it acquires a proper consistence." *U. S.*

The *London College* takes *five ounces* of ammoniac, and *eight fluid-ounces* of distilled vinegar; dissolves the ammoniac in the vinegar; and evaporates the solution by a slow fire, stirring constantly, to the proper consistence. The *Edinburgh College* takes *five ounces* of ammoniac and *nine fluidounces* of distilled vinegar; dissolves the ammoniac in the vinegar, and evaporates over the vapour-bath, frequently stirring. In the *Dublin* process, the ingredients are in the same proportion as in ours; but pure ammoniac is directed, the vinegar of squill is substituted for common vinegar, the straining is omitted, and the evaporation is conducted without the water-bath.

As ammoniac is not usually kept purified in our shops, the straining of

the solution in vinegar is directed as the most convenient method of separating impurities. Dr. Duncan says that the plaster, prepared in iron vessels, "acquires an unpleasant dark colour, from being impregnated with iron; whereas, when prepared in a glass or earthenware vessel, it has a yellowish-white colour, and more pleasant appearance."

Medical Properties. The ammoniac plaster is stimulant, and is applied over scrofulous tumours and chronic swellings of the joints, to promote their resolution. It often produces a papular eruption, and sometimes occasions considerable inflammation of the skin. Dr. Duncan has described a fatal case of diffuse inflammation following its use in a case of diseased knee-joint. W.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. *Lond., Dub.* EMPLASTRUM AMMONIACI ET HYDRARGYRI. *Ed.* *Plaster of Ammoniac with Mercury.*

"Take of Ammoniac a pound; Mercury three ounces; Olive Oil a fluidrachm; Sulphur eight grains. Add the Sulphur gradually to the heated Oil, constantly stirring with a spatula, until they unite; then rub the Mercury with them until the globules disappear; lastly, gradually add the Ammoniac, previously melted, and mix the whole together." *Lond.*

The *Edinburgh* process corresponds closely with the above.

"Take of Pure Gum Ammoniac a pound; Purified Mercury three ounces; Common Turpentine two drachms. Rub the Mercury with the Turpentine until the globules disappear, then gradually add the Ammoniac previously melted, and with a moderate heat rub them all together till they unite." *Dub.*

Of these processes the latter is preferable, as the unpleasant odour of the sulphurated oil is avoided, as well as the action of the sulphur upon the mercury, with which it must form an inactive sulphuret. But it should be recollected that the common turpentine of Great Britain is not the common white turpentine of our shops. The former is a thick liquid, the latter a soft solid. If the white turpentine be employed, it should be rendered sufficiently liquid by the admixture of Venice turpentine. As ammoniac is not fusible by heat, it must be brought to the proper consistence by dissolving it in a small quantity of hot water, straining and evaporating.

Medical Properties and Uses. This plaster unites with the stimulant power of the ammoniac the specific properties of the mercury, which is sometimes absorbed in sufficient quantity to affect the gums. It is used as a discutient in enlargement of the glands, tumefaction of the joints, nodes, and other indolent swellings, especially when dependent on a venereal taint. It is also sometimes applied over the liver in chronic hepatitis. W.

EMPLASTRUM AROMATICUM. *Dub.* *Aromatic Plaster.*

"Take of Frankincense [concrete juice of the *Abies excelsa*] three ounces; Yellow Wax half an ounce; Cinnamon Bark, in powder, six drachms; Oil of Pimento, Oil of Lemons, each, two drachms. Melt the Frankincense and Wax together, and strain. When, upon cooling, they begin to thicken, mix in the powdered Cinnamon previously rubbed with the Oils, and make a plaster." *Dub.*

As the virtues of this plaster depend chiefly upon volatile ingredients, it cannot be kept long without injury, and should therefore be extemporaneously prepared. It is not intended to be very adhesive, as, in order to maintain the due impression, its application must be frequently renewed. The volatility of the oils requires that it should be spread without being melted or heated more than is absolutely necessary to produce the proper

degree of softness. We are therefore recommended to spread it with the fingers.

Medical Properties and Uses. This is an elegant local stimulant, calculated when applied over the region of the stomach to allay nausea and vomiting, to correct flatulence, and to relieve the gastric uneasiness attendant upon dyspepsia. W.

EMPLASTRUM ASSAFÆTIDÆ. *U.S., Ed. Assafetida Plaster.*

"Take of Assafetida, Lead Plaster, each, *a pound*; Galbanum, Yellow Wax, each, *half a pound*; Diluted Alcohol *three pints*. Dissolve the Assafetida and Galbanum in the Alcohol with the aid of a water-bath, strain the liquor while hot, and evaporate to the consistence of honey; then add the Lead Plaster and Wax previously melted together, stir the mixture well, and evaporate to the proper consistence." *U.S.*

"Take of Litharge [Lead] Plaster and Assafetida, of each, *two ounces*; Galbanum and Bees'-wax, of each, *one ounce*. Liquefy the gum-resins together and strain them, then add the plaster and wax also in the fluid state, and mix them all thoroughly." *Ed.*

The directions of the present U.S. Pharmacopœia in relation to this plaster are more perfect than those of former editions; as they indicate the mode in which the gum-resins may be brought to the liquid state before being incorporated with the other ingredients. Galbanum melts sufficiently by the aid of heat to admit of being strained; but this is not the case with assafetida, which must be prepared by dissolving it in a small quantity of hot water or diluted alcohol, straining, and evaporating to the consistence of honey; and even the galbanum may be most conveniently treated in the same way. Formerly these gum-resins were ordered merely to be melted and strained, and such is at present the direction of the Edinburgh Pharmacopœia, unless the term "liquefy" be considered as leaving to the operator the choice of the mode in which they should be brought into the liquid state.

This plaster may be advantageously applied over the stomach or abdomen, in cases of hysteria attended with flatulence, and to the chest or between the shoulders in whooping cough. W.

EMPLASTRUM BELLADONNÆ. *U.S., Lond., Ed., Dub. Plaster of Belladonna.*

"Take of Resin Plaster *three ounces*; Extract of Belladonna *an ounce and a half*. Add the Extract to the Plaster, previously melted by the heat of a water-bath, and mix them." *U.S.*

The *London* and *Edinburgh* processes are the same as the above.

"Take of the Inspissated Juice of the Deadly Nightshade [Extractum Belladonnæ] *an ounce*; Soap Plaster *two ounces*. Make a plaster." *Dub.*

The most convenient method of forming this plaster, is to rub the ingredients together in an earthenware mortar placed in hot water, and then, having removed the mortar from the water-bath, to continue the trituration till the mixture cools. The preparation is a useful anodyne application in neuralgic and rheumatic pains, and in dysmenorrhœa. We have seen the constitutional effects of belladonna result from its external use. W.

EMPLASTRUM CANTHARIDIS. *Lond., Ed., Dub. Plaster of Spanish Flies.*

See CERATUM CANTHARIDIS. *U.S.*

EMPLASTRUM CANTHARIDIS COMPOSITUM. *Ed. Compound Plaster of Spanish Flies.*

“Take of Venice Turpentine, *four ounces and a half*; Burgundy Pitch and Cantharides, of each, *three ounces*; Bees'-wax *one ounce*; Verdigris *half an ounce*; White Mustard Seed and Black Pepper, of each, *two drachms*. Liquefy the Wax and Burgundy Pitch, add the Turpentine, and while the mixture is hot sprinkle into it the remaining articles, previously in fine powder and mixed together. Stir the whole briskly as it concretes on cooling.” *Ed.*

This is intended to be a powerful and speedy blistering plaster, and may probably prove beneficial in very urgent cases attended with much torpor of the skin; but great care should be observed not to allow it to remain too long, as unpleasant and tedious ulceration, if not gangrene, might result. To the cases of children it is wholly inapplicable. W.

EMPLASTRUM CERÆ. *Lond.* **EMPLASTRUM SIMPLEX.** *Ed. Wax Plaster.*

“Take of Wax, Suet, each, *three pounds*; Resin *a pound*. Melt them together and strain.” *Lond.*

“Take of Bees'-wax *three ounces*; Suet and Resin, of each, *two ounces*. Melt them together with a moderate heat, and stir the mixture briskly till it concretes on cooling.” *Ed.*

These plasters were originally intended for dressing blistered surfaces, in order to maintain a moderate discharge, for which purpose they are adapted by the stimulant properties of the resin. But their stiffness and adhesiveness render them unpleasant and of difficult management; and they have been entirely superseded by the resin cerate.

Off. Prep. Emplastrum Cantharidis, *Lond.*

W.

EMPLASTRUM FERRI. *U. S., Ed.* **EMPLASTRUM THURIS.** *Dub.* **EMPLASTRUM ROBORANS.** *Iron Plaster. Strengthening Plaster.*

“Take of Subcarbonate of Iron *three ounces*; Lead Plaster *two pounds*; Burgundy Pitch *half a pound*. Add the Subcarbonate of Iron to the Lead Plaster and Burgundy Pitch, previously melted together, and stir them constantly until they thicken upon cooling.” *U. S.*

The *Dublin* process differs from the above only in the employment of red oxide of iron instead of the subcarbonate, and of frankincense (see page 543) instead of Burgundy Pitch.

“Take of Litharge Plaster *three ounces*; Resin *six drachms*; Olive Oil *three fluidrachms and a half*; Bees'-wax *three drachms*; Red Oxide of Iron [Subcarbonate of Iron, *U. S.*] *one ounce*. Triturate the Oxide of Iron with the Oil, and add the mixture to the other articles previously liquefied by gentle heat. Mix the whole thoroughly.” *Ed.*

The present *U. S.* process is a great improvement upon that of the former editions, yielding a finer, more adhesive, and more efficient plaster. The preparation has enjoyed some popular celebrity, under the impression that it strengthens the parts to which it is applied; whence it has derived the name of strengthening plaster. It is used in those conditions of the loins, larger muscles, and joints, which, though usually ascribed to debility, are in fact most frequently dependent on rheumatic or other chronic inflammatory affections, and, if relieved by the plaster, are so in consequence of the gentle excitation which it produces in the vessels of the skin. It may also,

in some instances, give relief by affording mechanical support; but neither in this, nor in any other respect, can it be deemed very efficient. W.

EMPLASTRUM GALBANI. *Dub. Galbanum Plaster.*

“Take of Litharge Plaster [*Emplastrum Plumbi*] *two pounds*; Galbanum *half a pound*; Yellow Wax, sliced, *four ounces*. Add the Litharge Plaster and Wax to the Galbanum previously melted; then melt the whole together with a moderate heat, and strain.” *Dub.*

This is essentially the same in properties as the following, though somewhat less stimulating. W.

EMPLASTRUM GALBANI COMPOSITUM. *U.S. EMPLASTRUM GALBANI. Lond. Compound Galbanum Plaster.*

“Take of Galbanum *eight ounces*; Lead Plaster *three pounds*; Turpentine *ten drachms*; Burgundy Pitch *three ounces*. To the Galbanum and Turpentine, previously melted together and strained, add first the Burgundy Pitch, and afterwards the Lead Plaster melted over a gentle fire, and mix the whole together.” *U.S.*

The *London* process differs only in directing the common European turpentine instead of the white turpentine intended by our Pharmacopœia, and the concrete juice or unprepared resin of the *Abies excelsa*, instead of Burgundy pitch or the prepared resin.

Before being employed in this process, the galbanum should be purified, as it often contains foreign matters which must injure the plaster. It may be freed from these by melting it with a little water or diluted alcohol, straining, and evaporating to the due consistence.

This plaster is an excellent local stimulant in chronic scrofulous enlargements of the glands and joints. We have employed it with apparent advantage in some obstinate cases of this kind, which, after having resisted general and local depletion, blistering, and other measures, have yielded under its use. As a discutient it is also employed in the induration which sometimes remains after the discharge of abscesses. It is said to have been useful in rickets when applied over the whole lumbar region, and has been recommended in chronic gouty or rheumatic articular affections. It should not be employed in the discussion of tumours in which any considerable inflammatory action exists. W.

EMPLASTRUM GUMMOSUM. *Ed. Gum Plaster.*

“Take of Litharge Plaster [*Emplastrum Plumbi*] *four ounces*; Ammoniac, Galbanum, and Bees'-wax, of each, *half an ounce*. Melt the Gum-resins together and strain them; melt also together the Plaster and Wax; add the former to the latter mixture, and mix the whole thoroughly.” *Ed.*

The addition of ammoniac adds little to the virtues of this plaster, which closely resembles the compound galbanum plaster in its effects. The galbanum and ammoniac are best prepared by dissolving them in a small quantity of hot water or diluted alcohol, straining the solution, and evaporating it to the proper consistence for mixing with the other ingredients.

Off. Prep. Emplastrum Saponis, *Ed.*

W.

EMPLASTRUM HYDRARGYRI. *U.S., Lond., Ed. Mercurial Plaster.*

“Take of Mercury *six ounces*; Olive Oil, Resin, each, *two ounces*; Lead Plaster *a pound*. Melt the Oil and Resin together, and when they have become cool, rub the Mercury with them till the globules disappear; then gradually add the Lead Plaster, previously melted, and mix the whole together.” *U.S.*

The *London College* takes *three ounces* of mercury, *a pound* of lead plaster, *a fluidrachm* of olive oil, and *eight grains* of sulphur; gradually adds the sulphur to the heated oil, constantly stirring with a spatula until they unite; then rubs the mercury with them until the globules disappear; and finally adds by degrees the lead plaster previously melted with a slow fire, and mixes the whole together. The *Edinburgh* process corresponds with that of the *United States Pharmacopœia*, except that only one-half of the quantity of materials is employed, and *nine fluidrachms* of olive oil are directed instead of an ounce.

The sulphurated oil employed by the *London College* is intended to facilitate the extinguishment of the mercury; but as it operates by the union of the sulphur with the metal forming an inefficient sulphuret, it impairs the virtues of the plaster at least as much as it assists in its preparation. The melted resin and oil of the *United States* and *Edinburgh* process are decidedly preferable.

This plaster is employed to produce the local effects of mercury upon venereal buboes, nodes, and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. In these cases it sometimes acts as a powerful discutient. It is frequently also applied to the side in chronic hepatitis or splenitis. In habits peculiarly susceptible to the mercurial influence, it occasionally affects the gums.

From numerous observations made in France by Messrs. Serres, Gariel, Briquet, and others (see *Archives Generales*, viii, 468, and vi, 3ème Serie, 24), it appears that the mercurial plaster of the French Codex (*Emplastrum de Vigo cum Mercurio*), has the power, when applied upon a portion of skin affected with the eruption of small-pox, before the end of the third day of its appearance, to check the progress of the eruption and prevent suppuration and consequent pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. It is also thought that the course of the disease is favourably modified when the mercurial impression is produced upon the system. That the local effect is not ascribable to the mere exclusion of air is proved by the fact, that the application of common lead plaster was not followed by the same results. It is probable that other mercurial preparations would answer the same purpose; and the mercurial ointment of our *Pharmacopœia* has proved effectual, in our own hands, in rendering the eruption upon the face to a considerable extent abortive in one very bad case of small-pox. But as the most successful results were obtained with the plaster above mentioned, we give the formula of the French Codex for its preparation. The weights mentioned are those of the French metrical pound. (See *table in the Appendix*.)

Emplastrum de Vigo cum Mercurio. "Take of simple plaster [lead plaster] *two pounds eight ounces*; yellow wax *two ounces*; resin *two ounces*; ammoniac, bdellium, olibanum, and myrrh, each, *five drachms*; saffron *three drachms*; mercury *twelve ounces*; turpentine [common European] *two ounces*; liquid storax *six ounces*; oil of lavender *two drachms*. Powder the gum-resins and saffron, and rub the mercury with the storax and turpentine in an iron mortar until completely extinguished. Melt the plaster with the wax and resin, and add to the mixture the powders and volatile oil. When the plaster shall have been cooled, but while it is yet liquid, add the mercurial mixture, and incorporate the whole thoroughly." This should be spread upon leather or linen cloth, and applied so as effectually to cover the face or whatever other part it is desired to protect.

EMPLASTRUM OPII. *U. S., Lond., Ed., Dub. Opium Plaster.*

"Take of Opium, in powder, *two ounces*; Burgundy Pitch *three ounces*; Lead Plaster *a pound*; Boiling Water *four fluidounces*. Melt together the Lead Plaster and Burgundy Pitch; then add the Opium previously mixed with the Water, and boil them over a gentle fire to the proper consistence." *U. S.*

"Take of Hard Opium, in powder, *half an ounce*; Resin of the Spruce-fir [unprepared concrete juice of *Abies excelsa*], in powder, *three ounces*; Lead Plaster *a pound*; Water *eight fluidounces*. To the melted Plaster add the Resin, Opium, and Water; and boil down with a slow fire until the ingredients unite into a proper consistence." *Lond.*

"Take of Powder of Opium, *half an ounce*; Burgundy Pitch *three ounces*; Litharge plaster *twelve ounces*. Liquefy the Plaster and Pitch, add the Opium by degrees, and mix them thoroughly." *Ed.*

The *Dublin* process is the same as the *Edinburgh*.

The formula of the *U. S. Pharmacopœia* is preferable, as containing a much larger proportion of opium, which, in the others, is in a quantity too small for decided effect. The use of the water is to enable the opium to be more thoroughly incorporated with the other ingredients; but care should be taken that the moisture be well evaporated.

The opium plaster is thought to relieve rheumatic and other pains in the parts to which it is applied. W.

EMPLASTRUM PICIS. *Lond., Ed. Pitch Plaster.*

"Take of Burgundy Pitch *two pounds*; Resin of the Spruce-fir [unprepared concrete juice of *Abies excelsa*] *a pound*; Resin, Wax, each, *four ounces*; Expressed Oil of Nutmegs *an ounce*; Olive Oil, Water, each, *two fluidounces*. To the Pitch, Resin, and Wax, melted together, add first the Resin of the Spruce-fir, then the Oil of Nutmegs, the Olive Oil, and the Water. Lastly, mix the whole, and boil to the proper consistence." *Lond.*

"Take of Burgundy Pitch, *one pound and a half*; Resin and Bees' wax, of each, *two ounces*; Oil of Mace *half an ounce*; Olive Oil *one fluidounce*; Water *one fluidounce*. Liquefy the Pitch, Resin, and Wax with a gentle heat; add the other articles; mix them well together; and boil till the mixture acquires the proper consistence." *Ed.*

We presume that the *London expressed oil of nutmegs*, and the *Edinburgh oil of mace*, in the above formulæ, though these terms are not defined in the respective Pharmacopœias, have reference to the substance denominated, in the *Edinburgh Materia Medica* catalogue, *myristicæ adeps* or *concrete oil of nutmeg*. (See *Myristicæ Adeps*, page 471.) The driest white turpentine may be substituted for the resin of the spruce-fir, which is not always to be obtained in this country.

This is a rubefacient plaster applicable to catarrhal and other pectoral affections, chronic inflammation of the liver, and rheumatic pains in the joints and muscles. It often keeps up a serous discharge, which requires that it should be frequently renewed. The irritation which it sometimes excites is so great as to render its removal necessary. W.

EMPLASTRUM PICIS CUM CANTHARIDE. *U. S. EMPLASTRUM CALEFACIENS. Dub. Plaster of Pitch with Spanish Flies. Warming Plaster.*

"Take of Burgundy Pitch *three pounds and a half*; Cerate of Spanish Flies *half a pound*. Melt them together by means of a water-bath, and stir them constantly till they thicken upon cooling." *U. S.*

The *Dublin College* employs the same proportions.

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication. Still, however, in consequence of a peculiar susceptibility of the skin in some individuals, it occasionally blisters; and it has been recommended to diminish the proportion of the flies. But, while such a reduction would render the plaster insufficiently active in most cases, it would not entirely obviate the objection; as the smallest proportion of flies would vesicate in certain persons, and even the Burgundy pitch alone sometimes produces the same effect. In whatever mode, therefore, this plaster may be prepared, it cannot always answer the expectations which may be entertained; and the only plan, when the skin of any individual has been found to be very susceptible, is to accommodate the proportions to the particular circumstances of the case. Much, however, may be accomplished by proper care in the preparation of the plaster, towards obviating its tendency to blister. If the flies of the *Ceratum Cantharidis* should have been coarsely pulverized, the larger particles, coming in contact with the skin, will exert upon the particular part to which they are applied their full vesicatory effect, while, if reduced to a very fine powder, they would be more thoroughly enveloped in the other ingredients, and thus have their strength very much diluted. Hence the cerate, when used as an ingredient of the warming plaster, should contain the cantharides as minutely divided as possible, and if that usually kept is not in the proper state, a portion should be prepared for this particular purpose. A good plan, we presume, would be to keep the ingredients of the cerate used in this preparation, for a considerable time, at the temperature of 212° , and then strain it so as to separate the flies. (See *Ceratum Cantharidis*.) The mode frequently pursued of preparing the warming plaster by simply sprinkling a very small proportion of powdered flies upon the surface of Burgundy Pitch is altogether objectionable.

The warming plaster is employed in chronic rheumatism, and various chronic internal diseases attended with inflammation or an inflammatory tendency; such as catarrh, asthma, pertussis, phthisis, hepatitis, and the sequelæ of pleurisy and pneumonia. W.

EMPLASTRUM PLUMBI. *U. S., Lond.* EMPLASTRUM LITHARGYRI. *Ed., Dub.* Lead Plaster. Litharge Plaster.

"Take of Semivitrified Oxide of Lead, in very fine powder, *five pounds*; Olive Oil *a gallon*; Water *two pints*. Boil them together over a gentle fire, stirring constantly, until the Oil and Oxide of Lead unite into a Plaster. It will be proper to add a little boiling water, if that employed at the commencement be nearly all consumed before the end of the process." *U. S.*

The above process was precisely that of the old *London Pharmacopœia*. In the edition of that work for 1836, the quantities directed are *six pounds* of the oxide of lead, *a gallon* of olive oil, and *two pints* of water; but, as the Imperial measure is employed, the proportions are in fact nearly the same as before.

The *Edinburgh College* orders *five ounces* of litharge, *twelve fluidounces* of olive oil, and *three fluidounces* of water. The *Dublin* process does not differ materially from that of the London and *U. S. Pharmacopœias*.

The importance of this plaster, as the basis of most of the others, requires that we should enter somewhat in detail into an account of the principles and manner of its preparation.

It was formerly thought that the oil and oxide of lead entered into direct

union, and that the presence of water was necessary only to regulate the temperature, and prevent the materials from being decomposed by heat. The discovery, however, was afterwards made, that this liquid was essential to the process; and that the oil and oxide alone, though maintained at a temperature of 220° , would not combine; while the addition of water, under these circumstances, would produce their immediate union. It was now supposed that the oil was capable of combining only with the hydrated oxide of lead, and that the use of the water was to bring the oxide into this state; and in support of this opinion, the fact was advanced that the hydrated oxide of lead and oil would form a plaster, when heated together without any free water. But since the general reception of Chevreul's views in relation to oils and their combinations with alkalies and other metallic oxides, the former opinions have been abandoned; and it is now admitted that the preparation of the lead plaster affords a genuine example of saponification, as explained by that chemist. A reaction takes place between the oil and water, resulting in the formation of a sweetish substance called *glycerin*, and of two acid bodies, the *oleic* and *margaric acids*, to which, when animal fat is employed instead of olive oil, a third is added, namely, the *stearic*. The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact an oleo-margarate of lead. The *glycerin* remains dissolved in the water, or mechanically mixed with the plaster. That such is the correct view of the nature of this compound, is evinced by the fact, that if the oxide of lead be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water. According to a more recent chemical view, the fixed oils are compounds of the oily acids mentioned with the *oxide of glycerule*. When boiled with the oxide of lead and water, the oily acids combine with the metallic oxide to form the plaster, and the oxide of glycerule takes an equivalent of water and becomes *glycerin*. *Glycerule* is a hypothetical compound of carbon and hydrogen (C_6H_7), which unites with five equivalents of oxygen to form oxide of glycerule ($C_6H_7O_5$), also a hypothetical substance, and with an additional equivalent of water to form *glycerin* ($C_6H_7O_5 + Aq$).

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to *M. Henry* of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of the lead plaster to that obtained from Germany. Red lead, which is a deutoxide of the metal, forms a plaster with oil or fat, without the addition of water; but it is always of a deep brown colour, as if burnt. From more recent experiments of Soubéiran, it appears that massicot or even minium may be substituted for litharge, and a plaster of good consistence be obtained; but that a much longer time is required for completing the process than when the official formula is followed. When minium is used, the necessity for its partial deoxidation renders a longer continuance of the process necessary than with massicot.

Lead plaster has also been prepared by double decomposition between soap and acetate or subacetate of lead; but the results have not been so advantageous as to lead to the general adoption of this process. For particular

information on the subject the reader is referred to the *American Journal of Pharm.* ix. 127, and to the *Journal de Pharmacie*, xxiii. 163 and 322.

Preparation. The vessel in which the lead plaster is prepared, should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would therefore delay the process. Though water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil and cause the reduction of the metal. The waste must, therefore, be supplied by fresh additions as directed in the process; and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator. During the continuance of the boiling, the materials should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side, so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably in consequence partly of the vaporization of the water, partly of the escape of carbonic acid gas, which is liberated by the oily acids from some carbonate of lead usually contained in the litharge. (*Chevallier.*) The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the colour and consistence of the mass. The colour of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick, when a portion of the plaster taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red points, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and having been well kneaded under water, in order to separate the viscid liquid contained in the interior, should be formed into cylindrical rolls, and wrapped in paper.

Medical Properties and Uses. This plaster, which has long been known under the name of *diachylon*, is used as an application to excoriated surfaces, and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead-colic resulted from its long continued application to a large ulcer of the leg. (*Am. Jour. of Med. Sci.* xxiii. 246.) Its chief use is in the preparation of other plasters.*

* A plaster of carbonate of lead was originally introduced into our Pharmacopœia as a substitute for *Mahy's plaster*, so much employed in some parts of the United States; but was omitted in the last edition. It is a good application to surfaces inflamed or excoriated by friction; and may be resorted to with advantage in those troublesome cases of cutaneous irritation, and even ulceration, occurring upon the back and hips during long continued confinement to one position. We give the process as contained in the Pharmacopœia of 1830. "Take of Carbonate of Lead a pound; Olive Oil two pints; Yellow Wax four ounces; Lead Plaster a pound and a half; Florentine Orris, in powder, nine ounces. Boil together the Oil and Carbonate of Lead, adding a little water, and constantly stirring, till they are thoroughly incorporated; then add the Wax and Plaster, and when these are

S., Lond., Ed.*; Emp. Opii, *U. S., Lond., Ed., Dub.*; Emp. Resinæ, *U. S., Lond., Ed., Dub.*; Emp. Saponis, *U. S., Lond., Ed., Dub.*; Emp. Saponis Comp., *Dub.*; Unguentum Plumbi Comp., *Lond.* W.

EMPLASTRUM RESINÆ. *U. S., Lond.* EMPLASTRUM RESINOSUM. *Ed.* EMPLASTRUM LITHARGYRI CUM RESINÂ. *Dub.* EMPLASTRUM ADHÆSIVUM. *Resin Plaster. Adhesive Plaster.*

“Take of Resin, in powder, *half a pound*; Lead Plaster *three pounds*. To the Lead Plaster melted over a gentle fire add the Resin, and mix them.” *U. S., Lond.*

The *Edinburgh College* orders *five ounces* of the lead plaster, and *one* of resin; the *Dublin*, *three pounds and a half* of the former, and *half a pound* of the latter.

This preparation differs from the lead plaster in being more adhesive and somewhat more stimulating. It is the common adhesive plaster of the shops, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other, and a firm support is given to the granulations. It is usually spread for these purposes upon muslin; and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept in the shops ready spread; but as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. When the skin is very delicate, it occasionally excites some irritation, and under these circumstances a plaster may be substituted, containing a smaller proportion of resin. That originally employed by Baynton contained only six drachms of resin to the pound of lead plaster.

In order to render the plaster more adhesive, and less brittle in cold weather, it is customary with many apothecaries to employ a considerable proportion of Burgundy pitch or turpentine in its preparation; but these additions are objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended. If the remarks of Dr. Duncan on the compound soap plaster of the Dublin Pharmacopœia may be relied on, this might be advantageously substituted for the resin plaster in winter. (See *Emplastrum Saponis Compositum*.)

Off. Prep. Emplastrum Belladonnæ. *U. S., Lond., Ed.* W.

EMPLASTRUM SAPONIS. *U. S., Lond., Ed., Dub.* Soap Plaster.

“Take of Soap, sliced, *half a pound*; Lead Plaster *three pounds*. Mix the Soap with the melted Plaster, and boil for a short time.” *U. S.*

“Take of Litharge Plaster *four ounces*; Gum Plaster *two ounces*; Castile Soap, in shavings, *one ounce*. Melt the Plasters together with a moderate heat, add the soap, and boil for a little.” *Ed.*

In relation to the soap plaster of the London and Dublin Colleges, Dr. Montgomery, in his Observations upon the Dublin Pharmacopœia, makes the following remark. “I am informed by Mr. Scanlan, who prepares this plaster in large quantities, that the quantity of soap is twice too great, the

melted, sprinkle in the Orris, and mix the whole together.” By this process, a good plaster may be prepared, rather too soft, perhaps, at first, but soon acquiring the proper consistence.

plaster being, when prepared by this formula, quite pulverizable, and falling into crumbs." This effect is in some degree obviated by the gum plaster directed in the Edinburgh process. After the addition of the soap to the melted lead plaster, it is only necessary to continue the heat for a short time, till the soap is incorporated. Boiling is not necessary.

Soap plaster is considered discutient, and is sometimes used as an application to tumours.

Off. Prep. Emp. Belladonnæ, *Dub.*; Emp. Saponis Comp., *Dub.* W.

EMPLASTRUM SAPONIS COMPOSITUM vel ADHÆRENS. *Dub.* *Compound Soap Plaster, or Adhesive Plaster.*

"Take of Soap plaster *two ounces*; Litharge Plaster with Resin [Emplastrum Resinæ] *three ounces*. Make a plaster, which is to be melted and spread on linen." *Dub.*

Dr. Duncan, in his Dispensatory, makes the following observations in relation to this preparation: "The common resinous plaster is in cold weather too brittle, and apt to crack off from the linen on which it is spread; but by combining it in due proportion with soap plaster, it acquires greater pliability, without losing its adhesive property. In fact, this is the plaster commonly spread by a machine on webs of linen, and sold under the name of adhesive plaster." W.

ENEMATA.

Clysters.

These can scarcely be considered proper objects for official direction; but having been introduced into the British Pharmacopœias, the plan of this work requires that we should notice them. They are substances in the liquid form, intended to be thrown up the rectum, with the view either of evacuating the bowels, of producing the peculiar impression of a remedy upon the lower portion of the alimentary canal and neighbouring organs, or of acting on the system generally through the medium of the surface to which they are applied. They are usually employed to assist the action of remedies taken by the mouth, or to supply their place when the stomach rejects them, or is insensible to their impression. Sometimes they are preferably used when the seat of the disorder is in the rectum or its vicinity. As a general rule, three times as much of any remedy is required to produce a given impression by enema, as when taken into the stomach; but this rule should be acted on with caution, as the relative susceptibilities of the stomach and rectum are not the same in all individuals; and with regard to all very active remedies, the best plan is to administer less than the stated proportion. Attention should also be paid to the fact, that, by the frequent use of a medicine, the susceptibility of the stomach may be in some measure exhausted, without a proportionate diminution of that of the rectum.

When the object is to evacuate the bowels, the quantity of liquid administered should be considerable. For an adult from ten fluidounces to a pint, for a child of eight or ten years, half that quantity, for an infant within the year from one to three fluidounces, are about the proper proportions. Much larger quantities of mild liquids may sometimes be given with safety and advantage; as the bowels will occasionally feel the stimulus of distension, when they are insensible to impressions of an irritating character.

When the design is to produce the peculiar impression of the remedy

upon the neighbouring parts of the system, it is usually desirable that the enema should be retained; and the liquid vehicle should therefore be bland, and as small in quantity as is compatible with convenient administration. A solution of starch, flaxseed tea, or other mucilaginous fluid should be selected, and the quantity given should seldom exceed two or three fluid-ounces.

In every case, the patient should be instructed to resist any immediate disposition to discharge the injected fluid; and his efforts to retain it should be assisted, if necessary, by pressure with a warm folded towel upon the fundament.

The best instrument for administering enemata is an accurate metallic syringe. W.

ENEMA ALOES. *Lond. Clyster of Aloes.*

“Take of Aloes *two scruples*; Carbonate of Potassa *fifteen grains*; Decoction of Barley *half a pint* [Imperial measure]. Mix and rub them together.” *Lond.*

This is intended as a formula for the use of aloes in cases of ascarides in the rectum, and of amenorrhœa attended with constipation. W.

ENEMA CATHARTICUM. *Ed., Dub. Cathartic Clyster.*

“Take of Manna *an ounce*. Dissolve it in *ten fluidounces* of Compound Decoction of Chamomile, and add of Olive Oil *an ounce*, Sulphate of Magnesia *half an ounce*.” *Dub.*

“Take of Olive Oil *one ounce*; Sulphate of Magnesia *half an ounce*; Sugar *one ounce*; Senna *half an ounce*; Boiling Water *sixteen fluidounces*. Infuse the Senna for an hour in the Water; then dissolve the Salt and Sugar; add the Oil, and mix them by agitation.” *Ed.*

The laxative enema most commonly employed in this country, consists of a tablespoonful of common salt, two tablespoonfuls of lard or sweet oil, the same quantity of molasses, and a pint of warm water. It has the advantage of consisting of materials which are always at hand in families, is in all respects equal to the Dublin preparation, and, though less active than the Edinburgh, is preferable to it on ordinary occasions. W.

Off. Prep. Enema Fœtidum. *Ed., Dub.*

ENEMA COLOCYNTHIDIS. *Lond. Clyster of Colocynth.*

“Take of Compound Extract of Colocynth *two scruples*; Soft Soap *an ounce*; Water *a pint* [Imperial measure]. Mix and rub them together.” *Lond.*

This may be employed whenever a very powerful purgative impression is required upon the lower bowels, as in cases of obstinate colic and constipation. W.

ENEMA FŒTIDUM. *Ed., Dub. Fetid Clyster.*

“This is made by adding to the Cathartic Clyster *two drachms* of Tincture of Assafetida.” *Dub., Ed.*

It is carminative and antispasmodic, as well as laxative; but, when the peculiar influence of assafetida is desired by way of enema, we prefer the gum-resin itself rubbed up with hot water, in the proportion of one or two drachms to half a pint, of which the whole or a part may be given according to circumstances. W.

ENEMA OPII. *Lond., Dub. ENEMA OPII vel ANODYNUM. Ed. Clyster of Opium.*

“Take of Decoction of Starch *four fluidounces*; Tincture of Opium *thirty minims*. Mix them.” *Lond.*

The *Edinburgh College* boils *half a drachm* of starch in *two fluidounces* of water, and when it is cool enough for use, adds from *thirty minims* to a *fluidrachm* of tincture of opium.

The *Dublin College* mixes a *fluidrachm* of tincture of opium with *six fluidounces* of warm water.

Of these processes that of the *London College* is preferable, although the quantity of decoction of starch is unnecessarily large. In the *Dublin formula* there is too much both of the tincture and the vehicle. It must have happened to every one in the habit of prescribing opium in this way, to have seen a much greater effect produced by a certain amount of laudanum injected into the rectum than by one-third of the quantity swallowed. The *fluidrachm* contains at least one hundred drops of laudanum of the ordinary size, and not less than one hundred and twenty as they are often formed. From twenty to twenty-five drops are usually considered as a medium dose; so that the *Dublin College* orders five times as much by the rectum as is given by the mouth. Sixty drops, equivalent to about thirty minims, are abundantly sufficient. As the object is that the enema should remain in the rectum, the smaller the quantity of the vehicle the better; and a mucilaginous fluid is preferable to water, as it involves the tincture and prevents the irritation of the alcohol before the opium begins to take effect. The ordinary anodyne enema employed in this country consists of about sixty drops of laudanum and one or two fluidounces of flaxseed tea or solution of starch.

It is an admirable remedy in obstinate vomiting, strangury from blisters, painful affections of the kidneys, bladder, and uterus, and in the tenesmus of dysentery. It may also frequently be employed to produce the effects of opium upon the system; when circumstances prevent the administration of this medicine by the mouth. W.

ENEMA TEREBINTHINÆ. *Lond., Ed., Dub. Clyster of Turpentine.*

“Take of Oil of Turpentine *a fluidounce*; Yolk of Egg *a sufficient quantity*. Rub them together, and add of Decoction of Barley *nineteen fluidounces*.” *Lond.*

The *Edinburgh College* employs the same proportions, but substitutes water for decoction of barley.

“Take of Common Turpentine *half an ounce*; the Yolk of one Egg. Rub them together, and add gradually *ten ounces* of Water of a temperature not exceeding 100°.” *Dub.*

As the common turpentine alluded to in the *Dublin formula* is not usually kept in the shops of this country, we almost always employ the oil of turpentine, which is even more efficacious, and in no respect inferior for the purpose. (See *Oleum Terebinthinæ*.) W.

EXTRACTA.

Extracts.

Extracts, as the term is employed in the U. S., London, and *Edinburgh Pharmacopœias*, are solid substances, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing the vegetable to the action of a solvent, or by expressing its juice in the recent state. The *Dublin College* makes a distinction between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of

plants, calling the former *Extracta*, the latter *Succi Spissati*. But there is no such essential difference between these two sets of preparations, as to require that they should be separately classed; and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union. We shall consider them under the same head, taking care, however, to detail distinctly whatever is peculiar in the mode of preparing each.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principles of the plant, with as little of the inert matter as possible; though sometimes it may be desirable to separate the active ingredients from each other, when their effects upon the system are materially different; and this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, colouring matter, salts, and the peculiar principles of plants; to which, when a spirituous solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil—gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in the *Materia Medica*. There is one, however, which, from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive*, or, as it is sometimes called, *extractive matter*.

It has long been observed, that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes some chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep brown colour, and becoming itself insoluble. This substance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive name of *extractive*, derived from its very frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted by some chemists, who consider the phenomena supposed to result from its presence, as depending upon the mutual reaction of other principles; and in relation to Peruvian bark, it appears to have been proved, that the insoluble matter which forms during its decoction in water, is a compound of starch and tannin. A similar compound must also be formed in other cases when these two principles co-exist; but they are not always present in the same vegetable, nor can all the changes which have been attributed to extractive, be accounted for by their union, even when they are present; so that till further light is shed on the subject, it is best to admit the existence of a distinct substance, which, though not the same in all plants, possesses sufficient identity of character to be entitled, like sugar, resin, &c., to a distinctive name. The most interesting property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, which will then contain only the gum, sugar, saline matters, &c., which may have existed in the plant. If chlorine be passed through an infusion or decoction, a similar precipitate

is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has, therefore, been called, in its altered condition, oxidized extractive; but De Saussure ascertained that, though oxygen is absorbed during the process, an equal measure of carbonic acid gas is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is, therefore, obviously incorrect, and Berzelius proposes to substitute for it that of *apotheme*, synonymous with deposit. According to Berzelius, apotheme is not completely insoluble in water, but imparts a slight colour to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it, thus acquiring properties somewhat different, according to the source from which it is obtained. In this way, also, even when the extractive of a plant is itself medicinally inert, its conversion into apotheme may be injurious, by causing a precipitation of a portion of the active principle; and in practical pharmaceutic operations, this change should always, if possible, be avoided. With these preliminary views, we shall proceed to the consideration of the practical rules necessary to be observed in the preparation of extracts. We shall treat of the subject under the several heads, 1. of the extraction of the soluble principles from the plant; 2. of the method of conducting the evaporation; 3. of the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them; and 4. of the general directions of the several Pharmacopœias in relation to them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract; 1. by expression; 2. by the agency of a solvent.

1. *By expression.* This method is applicable only to recent vegetables. All plants cannot be advantageously treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of those which are succulent, a considerable proportion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects of this treatment. The plants should be operated upon, if possible, immediately after their collection. Mr. Battley, of London, recommends that, if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvass bag, and the liquid parts expressed. Mr. Brande states that light pressure only should be employed; as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. (*Manual of Pharmacy.*) The juice thus obtained is opaque and usually green, in consequence of the presence of green wax or chlorophylle, and of a portion of the undissolved vegetable fibre in a state of minute division. By heating the juice to about

160°, the albumen contained in it coagulates, and, involving the chlorophylle and vegetable fibre, forms a greenish precipitate. If the liquid be now filtered, it becomes limpid and nearly colourless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle; in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of a syrup.

2. *By solution.* The active principles of dried vegetables can be extracted only by means of a liquid solvent. The menstruum employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action, if necessary, by a higher degree of heat than the latter. Pump water is often unfit for the purpose, in consequence of the quantity of its saline matter, which, in some instances, may exert an unfavourable influence on the active principle, and must always be left in the extract. Rain or river or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble, or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils and the active principle of sarsaparilla; when the reaction of the water itself upon the vegetable principles is injurious, as sometimes happens; and finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The watery solution requires to be soon evaporated, as this fluid rather promotes than counteracts chemical changes; while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable; and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively, than to both united. Extracts obtained by the agency of water, are called *watery* or *aqueous extracts*, those by means of alcohol rectified or diluted, *alcoholic* or *spirituous extracts*.

The method of preparing the solution is by no means a matter of indifference. The vegetable should be thoroughly bruised, or reduced to the state of coarse powder, so as to allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved and inactive portion. When water is employed, it is usual to boil the medicine for a considerable length of time, and if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions, till the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the decomposition of many vegetable principles, or at least so modifies them as to render them inert; and the extracts prepared by decoction are usually less efficient than those prepared with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat used in their preparation. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot in-

fusion; in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter, and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is often preferable to the other modes, as starch, which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By *digestion*, though the solvent power of water is moderately increased, the advantage is more than counterbalanced by the increased disposition to spontaneous decomposition. *Hot infusion*, therefore, is to be preferred where the vegetable does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without any addition to its virtues. A convenient mode of performing this process, is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel with its mouth loosely stopped, then to pour on the boiling water, and having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated till the water comes away without any obvious impregnation. It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long continued evaporation, which has a tendency to injure the extract. It is better, therefore, to incur the risk, both where decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it, as the latter thus escapes exposure to unnecessary heat.

When alcohol is employed as a menstruum, the vegetable should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration; as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels. When alcohol and water are both used, it is best, as a general rule, to exhaust the vegetable with each separately, as the two menstrua require different modes of treatment. In whichever of these modes the extraction is effected, it requires the assistance of occasional agitation; and when the vegetable matter is very porous, and absorbs large quantities of the solvent, expression must be resorted to.

Acetic acid has recently been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and still stronger to alcohol to which strong acetic acid has been added. (*Journ. de Pharm.* N. S. i. 239.) This acid is used in the preparation of the acetic extract of colchicum of the London and Edinburgh Pharmacopœias.

The process of displacement has recently been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages; 1. that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion; 2. that it effects the

extraction much more quickly than can be done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and 3. that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing all the injurious effects of the subsequent evaporation. While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed; for, though an inexperienced or careless operator may lose by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskilfully prepared upon this plan. For an account of the mode of operating in the process of displacement, and of the instruments used, the reader is referred to pages 763 and 769.

Some prefer the mode of expression to that of displacement. This also is applicable both to watery and alcoholic menstua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances; and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of the common screw press, or other convenient instrument. Another portion of the menstruum may then be added and pressure again applied; and if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantage over that of displacement, that it yields solutions of more uniform concentration, that it does not require the material to be so carefully powdered nor otherwise so skilfully managed in order to insure favourable results, and finally that it occupies less time. (*Annal. der Pharm.* xxi. 299.)

2. *Mode of conducting the Evaporation.*

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact, that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapour. The operator should, therefore, observe two rules; 1. to conduct the evaporation at as low a temperature as is consistent with other objects; 2. to exclude atmospheric air as much as possible, and when this cannot be accomplished, to expose the liquid the shortest possible time to its action. According to Berzelius, the injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case; and, therefore, a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe, that decoctions generally let fall upon cooling a portion of insoluble matter; and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble tannate of starch formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a general rule, is to allow it to remain.

The method of evaporation usually resorted to in the case of the aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted, the better, provided the liquid is to be brought to the boiling point; for the temperature cannot exceed this, and the length of exposure is diminished. But even where this method is employed, it should not be continued till the completion of the evaporation; for when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire, before it has attained the consistence of thick syrup, and completing the evaporation either by means of a water-bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions, and evaporate each separately; for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. (*Mohr.*) But the mode of evaporation by boiling is always more or less objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by decoction.

Evaporation by means of the water-bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and the temperature being the same, or very nearly so, when the water-bath is kept boiling, there is greater risk of injurious action from the air. The use of the vapour-bath, as suggested by M. Henry, is perhaps preferable; as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, is less than 212° . We take the following description of the apparatus employed at the Central Pharmacy of Paris, from M. Chevallier's highly useful Manual. It consists of a covered boiler, containing water, the vapour of which is conducted through a pipe into evaporating vessels, communicating with each other by means of metallic tubes. These vessels have the form of an ordinary copper basin, over the top of which is soldered a shallow tin capsule intended to contain the liquor to be evaporated. The vapour from the boiler circulates through these vessels, and the water into which it condenses is allowed to escape through a stop-cock attached to the bottom of each vessel. From the last one of the series a tube passes into a vessel of water; so as to afford a slight pressure against the escape of any excess of vapour. The liquid to be evaporated is first distributed in two or three capsules, but when considerably concentrated is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid, if there are four vessels, is in that nearest the boiler about 198° F., in the fourth or most remote, about 135° . An incidental advantage of this apparatus is, that it affords a large supply of distilled water, which may be used for extracting the active matter from fresh portions of the vegetable, or for other purposes.

A good plan of evaporation, though slow, is to place the liquid in a broad shallow vessel, exposed in a stove or drying room to a temperature of about 100° , or a little higher, taking care that the air have free access in order to facilitate the evaporation. This mode is particularly applicable to all those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while those prepared in the ordinary way are almost black, and are opaque even in very

thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smiths' bellows, over the surface of the liquid; and in the case of those substances which are injured by heat and not by the action of atmospheric air, there is no doubt that the plan would be found useful.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for evaporation in vacuo invented by Mr. Barry, and described in the Lond. Journ. of Science and Arts, vol. viii. p. 360, is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapour more rapidly, and at a comparatively low temperature. The method of Barry consists in distilling the liquid into a large receiver from which the air has been expelled by steam, and in which the vapour is condensed by cold water applied to the surface of the receiver, so as to maintain a partial vacuum. Mr. Redwood has modified this process by keeping an air-pump in action during the evaporation, thus removing not only the air, but the vapour as fast as it forms, and maintaining a more complete vacuum than can be done by the condensation of the vapour alone. (*Journ. de Pharm.* N. S. i. 231.) Another method is to place the liquid under an exhausted receiver, together with some concentrated sulphuric acid, or chloride of calcium, which, by its affinity for water, assists the evaporation of the liquid. But from the expense and trouble of these modes of evaporation, they are not calculated for general use. Dr. Christison recommends as probably the most perfect and convenient method, especially with watery infusions and decoctions, to evaporate the fluid in a vacuum to the consistence of syrup, and then to complete the process in shallow vessels, exposed to a current of air without heat.

A more convenient plan of excluding the air, though it does not at the same time meet the object of reducing the requisite degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo*. Care, however, must be taken, that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water-bath.

In the concentration of alcoholic solutions, distillation should always be performed; as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water-bath should be employed to obviate any possible risk of injury from the fire. When the decoction or infusion, and tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together, while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is, that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat, therefore, should be applied to the bottom, and not to the sides of the vessel.

3. Condition and Preservation of Extracts.

Extracts are prepared of two different degrees of consistence, soft so that they may be readily made into pills, and hard that they may be pulverized. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophylle, harden by time, in consequence of the escape of their moisture; and it not unfrequently happens that small crystals of saline matter are formed in their substance. Most extracts, especially those containing azotized principles, are capable, when left to themselves, of producing nitrates. The air, moreover, exercises an unfavourable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt, or any other very soluble salt of difficult decomposition, the greater part of it is precipitated, in consequence of the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water. (*Berzelius.*)

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather, or a piece of bladder. (*Duncan.*) The dry extracts, being less liable to be affected by atmospheric oxygen, do not require so much care. The application of alcohol to the surface has a tendency to prevent mouldiness. A method of protecting extracts from the action of the air frequently resorted to, is to cover them closely with oiled bladder; but this, though better than to leave them uncovered, is not entirely effectual. Should the extract become too moist, it may be dried by means of a water-bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner, and incorporating with it a little distilled water. (*Chevallier.*)

Extracts from recent plants should always be prepared at the season when the plant is medicinally most active; and a good rule is to prepare them once a year.

4. General Official Directions.

“In the preparation of the Extracts, evaporate the moisture, as quickly as possible, in a broad, shallow dish, by means of a water-bath, until they have acquired the consistence proper for forming pills: and towards the end of the process, stir them constantly with a spatula. Sprinkle upon the softer Extracts a small quantity of Alcohol [Rectified Spirit, *Lond.*].” *U. S., Lond.*

“Extracts are usually prepared by evaporating the expressed juices of plants, or their infusions and decoctions in water, proof spirit, or rectified spirit, at a temperature not exceeding 212° F. by means of a vapour-bath. Most of them, however, may be obtained of greatly superior quality by the process of evaporation in vacuo. And the extracts of expressed juices cannot, perhaps, be better prepared than by spontaneous evaporation in shallow vessels, exposed to a current of air. Extracts should be evaporated to such a consistence as to form a firm pill-mass when cold.” *Ed.*

The *Dublin College* places the inspissated juices under a distinct head,

and gives directions for the watery extracts, under the title of *Extracta Simpliciora*, omitting, probably through inadvertence, the classification of the spirituous extracts which it also orders.

1. *Succi Spissati*. "The leaves used in the preparation of the inspissated juices should be gathered about the period when the herb begins to flower. The inspissation is best effected by evaporating the superfluous moisture with a *medium* heat by means of a vapour-bath, and constantly stirring with a spatula towards the close of the process." *Dub*.

2. *Extracta Simpliciora*. "All simple extracts, unless otherwise ordered, are to be prepared according to the following rule. Boil the vegetable matter in eight times its weight of water, till the liquid is reduced one-half; then express, and after the subsidence of the dregs filter; evaporate the liquor with a *superior* heat (between 200° and 212°) until it begins to thicken; finally, inspissate it with a *medium* heat (between 100° and 200°) obtained by a vapour-bath, frequently stirring, till it acquires the consistence proper for the formation of pills." *Dub*. W.

EXTRACTUM ACONITI. U.S., Lond., Ed. SUCCUS SPISSATUS ACONITI. *Dub*. *Extract of Aconite*.

This is prepared, according to the U. S. Pharmacopœia, from fresh Aconite, in the manner directed for extract of stramonium leaves. (See *Extractum Stramonii Foliorum*.)

"Take of fresh Aconite Leaves *a pound*. Bruise them in a stone mortar, sprinkling upon them a little water; then express the juice, and evaporate it, without straining, to the proper consistence." *Lond., Dub*.

"Take of the Leaves of Monkshood, fresh, *any convenient quantity*. Beat them into a pulp; express the juice; subject the residuum to percolation with Rectified Spirit, so long as the Spirit passes materially coloured; unite the expressed juice and the spirituous infusion; filter; distil off the spirit; and evaporate the residuum in the vapour-bath, taking care to remove the vessel from the heat so soon as the due degree of consistence shall be attained." *Ed*.

The U. S., London, and Dublin processes for this extract are the same; all consisting in the evaporation of the expressed juice of the leaves. The reader will find the general officinal directions at the close of our introductory observations in relation to extracts. Among these observations, he will also find rules which may be of practical use in regulating the various steps of the process under consideration.

In relation to the preparation of this extract, as well as of all others derived from the expressed juices of narcotic plants, the following summary of the plan pursued by Mr. Battley, an experienced apothecary of London, may be of service. Having passed the expressed juice through a fine hair sieve, he places it immediately upon the fire. Before it boils, a quantity of green matter rises to the surface, which in some plants is very abundant. This is removed by a perforated tin dish, and preserved. It ceases to appear soon after the liquid begins to boil. The boiling is continued till rather more than half the fluid has been evaporated, when the decoction is poured into a conical pan and allowed to cool. An abundant dark-green precipitate forms, from which the supernatant liquid is poured off, and having been reduced one-half by a second boiling, is again allowed to stand. The precipitate which now falls is less green than the first. The remaining fluid is once more placed over the fire, and allowed to boil till it assumes the consistence of syrup, when it is removed. The matter at first collected by filtration, together with that precipitated, is now incorporated

with it, and the whole placed in a metallic pan, and by means of a water-bath evaporated to the consistence of an extract. In the latter part of the process, care is necessary to prevent any part of the extract from hardening on the sides of the vessel, as it thus loses its fine-green colour and becomes proportionably feeble.

The superiority of this plan over a continuous boiling is, that the portions of active matter which are deposited at different stages of the process, are subjected for a shorter time to heat than if allowed to remain in the liquor, and consequently are less deteriorated. The matter which coagulates before the fluid boils, is chiefly albumen, embracing portions of chlorophylle and of the undissolved vegetable fibre. It might probably be thrown away without diminishing the virtues of the extract; but as chlorophylle, though itself inactive, has often associated with it a portion of the active principle, it is the most economical plan to incorporate it with the other matters. Mr. Brande states, that one cwt. of fresh aconite yields about five pounds of extract. According to Geiger, one pound yields an ounce and a half.

The Edinburgh process, which was adopted from the Prussian Pharmacopœia, first expresses the leaves, then digests the residue in alcohol, and evaporates the two liquids together. This is an improvement on the other process, as the residue of the leaves after the expression of the juice is still very acrid. But the evaporation of the expressed juice and the tincture should be carried on separately to the consistence of a syrup, since by the present plan the active matter of both liquids is exposed to heat during the time necessary for the evaporation of the whole.

When properly prepared by means of a water-bath, according to the U. S. and London process, which is that of Störck, this extract has a yellowish-brown colour, with a disagreeable narcotic odour, and the acrid taste of the plant. Prepared according to the Edinburgh process, it is said to be more acrid and more active as a medicine. The extract of aconite may be given in the dose of one or two grains, night and morning, to be gradually increased till the system is affected. Twenty grains or more have been given in the course of a day. Dr. Turnbull states, that he has tried several extracts of aconite made by evaporating the expressed juice, and found them almost inert. W.

EXTRACTUM ACONITI ALCOHOLICUM. *U. S. Alcoholic Extract of Aconite.*

“Take of Aconite, in coarse powder, *a pound*; Diluted Alcohol *four pints*. Moisten the Aconite with half a pint of the Diluted Alcohol, and, having allowed it to stand for twenty-four hours, transfer it to an apparatus for displacement, and add gradually the remainder of the Diluted Alcohol. When the last portion of this shall have penetrated the Aconite, pour in sufficient water from time to time to keep the powder covered. Cease to filter when the liquid which passes begins to produce a precipitate, as it falls, in that which has already passed. Distil off the Alcohol from the filtered liquor, and evaporate the residue to the proper consistence.” *U. S.*

This is essentially the process of the French Codex. The water added is merely intended to expel that portion of the spirituous solution remaining in the Aconite; and the filtration is directed to cease when a precipitate begins to appear, because this is an indication that the water is passing. It is important that the heat employed in the evaporation should not be greater than that produced by a vapour-bath, as otherwise decomposition will be apt to ensue.

If made from recently dried leaves, which have not yet been impaired by

time, this is a good preparation of aconite, and is believed to be more powerful, and to keep better, than the inspissated juice. The dose is half a grain, or a grain, to be gradually increased if necessary. W.

EXTRACTUM ALOËS PURIFICATUM. *Lond.* **EXTRACTUM ALOËS HEPATICÆ.** *Dub.* *Purified Extract of Aloes.*

"Take of Aloes, in powder, *fifteen ounces*; Boiling Water *a gallon* [Imperial measure]. Macerate for three days with a gentle heat; then strain the liquor, and set it by that the dregs may subside. Pour off the clear liquor, and evaporate it to a proper consistence." *Lond.*

The *Dublin College* prepares this extract according to the general directions. (See page 933.)

The object of this process is to separate from aloes the resinous matter, the *apotheme* of Berzelius, which is supposed to irritate the bowels, without possessing purgative properties; but the truth appears to be, that, when deprived of a small proportion of adhering extractive, this matter is quite inert. It cannot, therefore, injuriously affect the virtues of the medicine; and as it exists in comparatively small proportion, and during the process a part of the extractive becomes insoluble, the preparation may be considered as at best unnecessary. The dose of the purified aloes is from five to fifteen grains.

Off. Prep. Extractum Colocynthis Compositum, *Lond.*

W.

EXTRACTUM ANTHEMIDIS. *Ed.* **EXTRACTUM CHAMÆMELI.** *Dub.* *Extract of Chamomile.*

"Take of Chamomile [dried flowers] *a pound*. Boil it with *a gallon* [Imperial measure] of Water down to four pints; filter the liquor hot; evaporate in the vapour-bath to the proper consistence." *Ed.*

The *Dublin College* prepares this extract according to the general process for *simple extracts*. (See page 933.)

According to Mr. Brande, one cwt. of dried chamomile flowers affords upon an average 48 pounds of extract.

This extract has a deep brown colour, and the bitter taste of chamomile, but is wholly destitute of aroma, the volatile oil having been entirely driven off during the process. It does not, therefore, possess the peculiar virtues of the flowers; but is simply a mild bitter, which may sometimes be advantageously combined with laxatives and mineral tonics in debilitated states of the digestive organs. All the effects of the flowers may be obtained from it by adding a little of the oil of chamomile. It is most used, however, as a vehicle for other tonics in the pilular form. It has been omitted in the last edition of the U. S. Pharmacopœia. The dose is from ten to twenty grains. An extract may be prepared, having the peculiar flavour as well as bitterness of chamomile, by macerating the flowers in water, and evaporating the infusion in vacuo. W.

EXTRACTUM ARTEMISIÆ ABSINTHII. *Dub.* *Extract of Wormwood.*

This extract, which is directed only by the *Dublin College*, is prepared from the tops of Wormwood according to the general formula of that College for *simple extracts*. (See page 933.) It retains, to a certain extent, the bitterness of the plant, without the strong odour and peculiar taste dependent on the volatile oil which is driven off by the boiling. It is, however, in no respect superior to other bitter extracts, and is very seldom used. The dose is from ten to twenty grains. W.

EXTRACTUM BELLADONNÆ. U.S., Lond., Ed. Succus Spissatus Belladonnæ. Dub. Extract of Belladonna.

This is prepared from the fresh leaves of the *Atropa Belladonna* in the manner directed by the U. S. Pharmacopœia for extract of stramonium leaves (see *Extractum Stramonii Foliorum*); and by the London and Dublin for extract of aconite (see *Extractum Aconiti*).

“Take of Belladonna fresh, *any convenient quantity*. Bruise it in a marble mortar into a uniform pulp; express the juice; moisten the residuum with water, and express again. Unite the expressed fluids, filter them, and evaporate the filtered liquid in the vapour-bath to the consistence of firm extract, stirring constantly towards the close.” *Ed.*

From the experiments of MM. Solon and Soubeiran, it appears that, in relation to this extract, the insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, are nearly if not quite inert; so that advantage might result from clarifying the juice by these means before evaporating it. (See General Observations on Extracts, p. 927.) Mr. Brande states that one cwt. of fresh belladonna yields from 4 to 6 pounds of extract. According to M. Recluz, nearly ten parts may be obtained from one hundred. The extract employed in this country is brought chiefly from England. It has usually a dark-brown colour, a slightly narcotic not unpleasant odour, a bitterish taste, and a soft consistence which it long retains. Asparagin has been found in this extract. (*Journ. de Pharm.* xxi. 178.)

Its medical properties and uses have been detailed under the head of Belladonna. A few words in relation to its mode of application may be proper here. For the dilatation of the pupil, it is either mixed with water to the consistence of cream and rubbed on the brow and eyelids, or dissolved in water and dropped into the eye. In rigidity of the os uteri, it is applied at intervals to the neck of the uterus, mixed with simple ointment in the proportion of two drachms to an ounce. In irritability of the bladder, chordee, spasm of the urethra, and painful constriction of the rectum, it may either be rubbed in the form of ointment upon the perineum, along the urethra, &c., or may be used in the form of enema; but care is requisite not to introduce it too freely into the bowel. It is sometimes smeared upon the bougie mixed with oil, in the treatment of stricture of the urethra. In the form of ointment it has been beneficially employed in phymosis and paraphymosis, and in that of plaster or ointment, in local pains of a neuralgic or rheumatic character. (See *Emplastrum Belladonnæ*.) The dose of the extract is uncertain on account of its variable strength. The best plan is to begin with one-quarter or one-half of a grain, repeated two or three times a day, and gradually to increase the dose till the effects of the medicine are experienced. To a child two years old not more than one-twelfth of a grain should be administered at first.

Off. Prep. Emplastrum Belladonnæ. U. S., Lond., Ed., Dub. W.

EXTRACTUM BELLADONNÆ ALCOHOLICUM. U.S. Alcoholic Extract of Belladonna.

This is directed by the U. S. Pharmacopœia to be prepared from Belladonna, in coarse powder, in the same manner as the alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum*.) It is a good preparation, though less necessary than some other spirituous extracts of the narcotic plants, as the inspissated juice or common extract of belladonna can generally be procured of good quality. It is one of the officinals of the French Codex. The dose to begin with is half a grain or a grain. W.

EXTRACTUM CINCHONÆ. *U. S., Ed., Dub.* EXTRACTUM CINCHONÆ CORDIFOLIÆ. EXTRACTUM CINCHONÆ LANCIFOLIÆ. EXTRACTUM CINCHONÆ OBLONGIFOLIÆ. *Lond. Extract of Peruvian Bark.*

“Take of Peruvian Bark, in coarse powder, *a pound*; Alcohol *four pints*; Water *a sufficient quantity*. Macerate the Peruvian Bark with the Alcohol for four days; then filter by means of an apparatus for displacement, and when the liquid ceases to pass, pour gradually upon the Bark sufficient Water to keep its surface covered. When the filtered tincture measures four pints, set it aside, and proceed with the filtration until six pints of infusion are obtained. Distil off the alcohol from the tincture, and evaporate the infusion, till the liquids respectively are brought to the consistence of thin honey; then mix them, and evaporate so as to form an extract.” *U. S.*

“Take of Cinchonia Cordifolia, bruised, *fifteen ounces*; Distilled Water *four gallons* [Imperial measure]. Boil down with a gallon of Water to six pints, and strain the liquor while hot. In the same manner boil down with an equal measure of Water four times, and strain. Lastly, having mixed all the liquors together, evaporate them to the proper consistence. Prepare the Extract of Cinchona Lancifolia, and Cinchona Oblongifolia, in the same manner as that of Cinchona Cordifolia.” *Lond.*

“Take of any of the varieties of Cinchona, but especially the Yellow or Red Cinchona, in fine powder, *four ounces*; Proof Spirit *twenty-four fluidounces*. Percolate the Cinchona with the Spirit; distil off the greater part of the spirit; and evaporate what remains in an open vessel over the vapour-bath to a due consistence.” *Ed.*

The *Dublin College* takes *a pound* of coarsely powdered pale bark and *six pints* of water; boils for fifteen minutes in a loosely covered vessel, and filters the decoction while hot; boils the residue again in an equal quantity of water, and filters as before; repeats the boiling and filtration in like manner a third time; then mixes the decoctions, and evaporates them to a proper consistence. The College also directs that the extract should be kept *soft*, so as to be fit for forming pills, and *hard* that it may be pulverized.

Of the different officinal extracts of bark for which directions are given above, we decidedly prefer that of the United States or Edinburgh Pharmacopœia. The extract of the London and Dublin Colleges is an injudicious preparation. In the first place, the water does not nearly exhaust the bark, and in the second, the boiling favours the formation of an insoluble compound of starch and tannin, which carries with it a portion of the alkaline principles, and, though retained in the extract, is probably less efficient as a medicine than a more soluble compound containing an equal proportion of the active matter. According to the suggestion of M. Henry, Jun., it is not improbable that the different colouring matters in the bark act in relation to the quinia and cinchonia the part of an acid, sharing at a high temperature these bases with the kinic acid, and forming with them insoluble if not inert compounds. Besides, we cannot by any means be certain that a long continued heat of 212° may not determine an actual decomposition of a portion of these alkalies, and the formation of new principles. It is very desirable that the evaporation, in the preparation of this extract, should be effected at a low temperature.

A very good extract of bark was formerly prepared, in the shops of Philadelphia, by macerating cinchona for a considerable length of time in a large proportion of water, and slowly evaporating the infusion, by a very

moderate heat, in large shallow dishes placed upon the top of a stove. Before the use of the sulphate of quinia had superseded that of most other preparations of bark, we employed this extract with success in the treatment of intermittents, and found ten grains of it equivalent to nearly a drachm of the powdered cinchona.

According to Mr. Brande, one cwt. of fine crown bark (best pale bark) yields, on an average, 28 pounds of watery extract, and 25 pounds of alcoholic extract. It is best that the bark should be only coarsely powdered when submitted to decoction or maceration; as in this state it is sufficiently penetrable by the solvent, and more readily separated after being exhausted. The extract should always be brought to the hard dry state in which it may be pulverized; as it is thus less apt to be injured by exposure, and in the state of powder may be more uniformly incorporated with other substances. It is best prepared from the red or yellow (*Calisaya*) bark.

Medical Uses. The extract of Peruvian bark is at present much less employed than before the discovery of quinia. It is still, however, occasionally prescribed as a tonic in combination with other medicines; and as it possesses, when properly prepared with a spirituous menstruum, almost all the active principles as they exist in the bark itself, it may be used in preference to the sulphate of quinia, whenever it is supposed that the latter is incapable of exerting all the curative influence of cinchona. The dose is from ten to thirty grains, equivalent to about a drachm of the powdered bark.

W.

EXTRACTUM COLCHICI ACETICUM. *Lond., Ed. Acetic Extract of Colchicum.*

"Take of fresh Colchicum Cormus [bulb] *a pound*; Acetic Acid *three fluidounces*. Bruise the Cormus, gradually sprinkling in the Acetic Acid; then express the juice, and evaporate it, in an earthen vessel not glazed with lead, to the proper consistence." *Lond.*

"Take of Bulb of Colchicum *a pound*; Pyroligneous Acid *three fluidounces*. Beat the Colchicum to a pulp, gradually adding the acid; express the liquor and evaporate it in a porcelain vessel (not glazed with lead) over the vapour-bath to the due consistence." *Ed.*

The use of the acetic acid in this preparation, is to render more soluble the alkaline principle upon which the virtues of meadow-saffron are thought to depend. The acetic extract of colchicum is highly commended by Sir C. Scudamore, who, however, prefers it made by evaporating to the consistence of honey a saturated acetic infusion of the dried bulb. (*Lond. Med. Gazette*, Dec. 10, 1841.) The dose of the extract is one or two grains, to be repeated two or three times a day, and increased if necessary.

W.

EXTRACTUM COLCHICI CORMI. *Lond. Extract of Colchicum Cormus.*

This is prepared in the manner directed for Extract of Aconite.

There scarcely seems to be occasion for both this and the preceding extract of meadow-saffron bulb. Neither of them can properly be prepared in this country, as we want the fresh bulb. The dose is one or two grains.

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims or more. It is prepared by expressing the fresh bulb, allowing it to stand for forty-eight hours, so that the feculent matter may be deposited, then adding one quarter of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering.

W.

EXTRACTUM COLOCYNTHIDIS. *Lond., Ed.* EXTRACTUM COLOCYNTHIDIS SIMPLEX. *Dub. Extract of Colocynth.*

“Take of Colocynth, sliced, *a pound*; Distilled Water *two gallons* [Imperial measure]. Mix them and boil with a slow fire for six hours, occasionally adding Distilled Water, so that it may always fill the same measure. Strain the liquor while hot; and lastly, evaporate to the proper consistence.” *Lond.*

The *Edinburgh* process corresponds closely with the London.

“Take of Pulp of Colocynth *a pound*; Water *a gallon*. Boil down to four pints, and strain the liquor while hot; then evaporate it to a proper consistence.” *Dub.*

In the formula of the Dublin College, the proportion of colocynth is too large, if the pulp only, without the seeds, is intended; as, in consequence of the porous nature of the medullary matter, it absorbs nearly the whole of the water, and almost precludes the possibility of boiling as directed. Dr. Duncan found half a pound of colocynth to contain 2770 grains of seeds, which boiled by themselves yielded almost nothing to water, and 800 grains of pith, which was easily boiled in four pounds of water, but absorbed almost the whole of it. The decoction, when expressed, although it contained no starch, gelatinized on cooling. By boiling the residuum in four pounds of fresh water, he obtained a decoction, which, mixed with that previously obtained, yielded upon evaporation 360 grains of a pale-brown, semi-transparent, dry, elastic extract, of intense bitterness.

The decoction is ordered to be strained while hot, because the gelatinous consistence which it assumes on cooling prevents it from readily passing through the strainer. The French Codex directs, instead of the decoction, an infusion prepared by maceration in cold water. But the aqueous extract of colocynth, however made, is not an eligible preparation; as water is not the best solvent of the active bitter principle, while it takes up much inert matter, so that the officinal extract is even feebler than colocynth itself, without having any peculiar merit to recommend it. Besides, according to Mr. Brande, it is invariably either mouldy, or so tough and hard as to resist trituration and formation into pills. It has no place in our national Pharmacopœia, and is little used. The dose is from five grains to half a drachm. W.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. *U. S., Lond., Dub. Compound Extract of Colocynth.*

“Take of Colocynth, deprived of the seeds and sliced, *six ounces*; Aloes, in powder, *twelve ounces*; Scammony, in powder, *four ounces*; Cardamom, in powder, *an ounce*; Soap [Castile] *three ounces*; Diluted Alcohol *a gallon*. Macerate the Colocynth in the Diluted Alcohol, with a gentle heat, for four days. Express and filter the liquor, and add to it the Aloes, Scammony, and Soap; then evaporate to the proper consistence, and, near the end of the process, mix the Cardamom with the other ingredients.” *U. S.*

The processes of the *London* and *Dublin Colleges* correspond with the above except in phraseology. The former College, however, directs the purified extract of aloes, the latter, hepatic aloes.

The object of the soap in this formula is to improve the consistence of the mass, which it renders more soluble in the liquors of the stomach when hardened by time. It may possibly also serve the purpose of qualifying the action of the aloes. Diluted alcohol is a much better solvent of the active principle of colocynth than water. The proper consistence alluded to in this process, is that which is adapted to the formation of pills.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, &c., with one or more of which it is very often united in prescription. In such combination it is much employed wherever an active cathartic is desirable, particularly in the commencement of fevers and febrile complaints, in congestion of the liver or portal system, and in obstinate constipation. In small doses it is an excellent laxative in that state of habitual costiveness depending on a want of the due irritability of the bowels, which often occurs in old people. The dose is from five to thirty grains, according to the effect to be produced, and the susceptibility of the bowels. A very eligible combination is in the compound cathartic pill of the U. S. Pharmacopœia.

Off. Prep. Enema Colocynthis, *Lond.* Pilulæ Catharticæ Compositæ, *U. S.* W.

EXTRACTUM CONII. *U. S., Lond., Ed.* SUCCUS SPISSATUS CONII. *Dub.* *Extract of Hemlock.*

This is prepared from fresh Hemlock Leaves, in the manner directed by the U. S. Pharmacopœia for extract of stramonium leaves [see *Extractum Stramonii Foliorum*], and by the *London* and *Dublin* for extract of aconite (see *Extractum Aconiti*).

“Take of Conium *any convenient quantity*. Beat it into a uniform pulp in a marble mortar, express the juice, and filter it. Let this juice be evaporated to the consistence of a very firm extract either in a vacuum with the aid of heat, or spontaneously in shallow vessels exposed to a strong current of air freed of dust by gauze-skreens. This extract is of good quality only when a very strong odour of conia is disengaged by degrees on its being carefully triturated with Aqua Potassæ.” *Ed.*

The most important point in the preparation of this extract is to evaporate the juice without an undue degree of heat. At a temperature of 212° or upwards, its active principle undergoes rapid decomposition, being converted into resinous matter and ammonia. This is detected by the operator by the ammoniacal odour mixed with that which is peculiar to the plant. When evaporated over a fire, the juice always to a certain extent undergoes this decomposition, and is not exempt from it even when the heat is regulated by a water-bath. Hence the propriety of the directions of the Edinburgh College. In Edinburgh, a very fine extract is prepared by evaporating the juice first in a vacuum, and afterwards in shallow vessels, with a current of air, at common temperature. Long continued exposure to the air is productive of the same result as too much heat, so that old extracts are frequently destitute of activity. (*Journ. de Pharm.* xxii. 416.) No one of the extracts is more variable in its qualities than this. The season at which the herb is collected, the place and circumstances of its growth, the method of preparing the extract, are all points of importance, and are all too frequently neglected. (See *Conii Folia*.) In this country the process is often very carelessly conducted; and large quantities of an extract prepared by boiling the plant in water and evaporating the decoction, have been sold as the genuine drug. The apothecary should always prepare the extract himself, or procure it from persons in whom he can have entire confidence. That imported from London is usually the best. The activity of any specimen of the extract may be judged of by rubbing it with potassa, which, disengaging the *conia* and rendering it volatile, gives rise to the peculiar odour

of that principle. If no odour be evolved under these circumstances, the extract may be deemed inert.

Extract of hemlock should have a fresh olive or greenish colour, a strong narcotic somewhat fetid odour, and a bitterish saline taste. According to Brande, from three to five pounds are obtained from one cwt. of the leaves. M. Recluz got rather more than an ounce from sixteen ounces. Of the medical properties and application of this extract, we have spoken under the head of *Conii Folia*. The dose is three grains twice a day, to be gradually increased till evidences of its action upon the system are afforded. It may be administered in pill or solution.

Off. Prep. *Pilulæ Conii Compositæ.*” *Lond.*

W.

EXTRACTUM CONII ALCOHOLICUM. *Alcoholic Extract of Hemlock. U.S.*

This is prepared, according to the U. S. Pharmacopœia, from Hemlock Leaves, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum*.)

It is one of the French officinal extracts. The same caution is requisite in evaporating in this case as in that of the inspissated juice or common extract. The dose, to begin with, is two or three grains.

W.

EXTRACTUM DIGITALIS. *Lond., Ed. Extract of Foxglove.*

This is prepared from the fresh leaves, in the manner directed by the London College for extract of aconite (see *Extractum Aconiti*), by the Edinburgh for extract of hemlock (see *Extractum Conii*).

It is a new preparation of the London and Edinburgh Colleges, and appears to us, considering the activity of the leaves themselves, and the at least equal uncertainty of the extract, to be quite superfluous. The dose is from half a grain to two grains.

W.

EXTRACTUM DULCAMARÆ. *U.S. Extract of Bittersweet.*

This is prepared, according to the U. S. Pharmacopœia, from Bittersweet, in coarse powder, in the manner directed for extract of gentian. (See *Extractum Gentianæ*.)

This has been newly introduced into the U. S. Pharmacopœia. It is a preparation well known on the continent of Europe, but little used in this country or Great Britain. The dose is from five to ten grains; but much more may be given with impunity.

W.

EXTRACTUM GENTIANÆ. *U.S., Lond., Ed., Dub. Extract of Gentian.*

“Take of Gentian, in coarse powder, a pound; Water a sufficient quantity. Mix the Gentian with a pint of the Water, and, after allowing the mixture to stand for twenty-four hours, introduce it into an apparatus for displacement, and pour Water upon it gradually until the liquid passes but slightly impregnated with the properties of the Gentian. Heat the filtered liquid to the boiling point, strain, and evaporate to the proper consistence.”

U. S.

“Take of Gentian, sliced, two pounds and a half; Boiling Distilled Water two gallons [Imperial measure]. Macerate for twenty-four hours; then boil down to a gallon, and strain the liquor while hot; lastly, evaporate to the proper consistence.” *Lond.*

“Take of Gentian any convenient quantity. Bruise it to a moderately fine powder, mix it thoroughly with half its weight of Distilled Water; in twelve hours put it into a proper percolator, and exhaust it by percolation

with temperate Distilled Water; concentrate the liquid, filter it before it becomes too thick, and evaporate in the vapour-bath to the due consistence." *Ed.*

The *Dublin College* prepares this extract according to the general process of that College for *simple extracts*. (See page 933.)

The London and Dublin Colleges adhere to the old mode of preparing this extract by decoction; but in the U. S. and Edinburgh Pharmacopœias the better process of percolation with cold water has been adopted. MM. Guibourt and Cadet de Vaux obtained by the maceration in cold water an extract not only greater in amount, but more transparent, more bitter, and possessing more of the colour and smell of the root than that prepared by decoction. Guibourt attributes this result to the circumstance, that as gentian contains little, if any starch, it yields nothing to boiling which it will not also yield to cold water, while decoction favours the combination of a portion of the colouring matter with the lignin. For rules in relation to the proper management of the displacement process, the reader is referred to pages 763 and 769; and for observations upon the best modes of evaporation in the formation of extracts, to page 929. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian is nearly inodorous, very bitter, of a dark brown colour approaching to black, shining, and tenacious. It is frequently used as a tonic in the form of pill, either alone or in connexion with metallic preparations. The dose is from ten to thirty grains.

Off. Prep. Pilulæ Aloës Compositæ, *Lond.*

W.

EXTRACTUM HÆMATOXYLI. *U. S., Lond., Ed.* EXTRACTUM HÆMATOXYLI CAMPECHIANI. *Dub.* *Extract of Logwood.*

"Take of Logwood, rasped, *a pound*; Water *a gallon*. Boil down to four pints, and strain the liquor while hot; then evaporate to the proper consistence." *U. S.*

"Take of Logwood, in fine chips, *a pound*; Boiling Water *a gallon* [Imperial measure]. Macerate for twenty-four hours, then boil down to four pints, strain, and concentrate in the vapour-bath to the due consistence." *Ed.*

The *London College* prepares it in the manner directed for extract of gentian (see *Extractum Gentianæ*); the *Dublin College*, according to their general process for *simple extracts*. (See page 933.)

The evaporation should be carried so far, that the extract may be dry and brittle when cold. About twenty pounds of it are obtained from one cwt. of logwood. (*Brande.*) It is of a deep ruby colour, and an astringent sweetish taste; and possesses all the medical virtues of the wood from which it is procured. If given in pills, these should be recently made, as, when long kept, they are said to become so hard as sometimes to pass unchanged through the bowels. The extract, however, is best administered in solution. The dose is from ten to thirty grains. This extract is said to be prepared largely in Yucatan and other parts of Mexico. (*Journ. of the Phil. Col. of Pharm.* vi. 87.)

W.

EXTRACTUM HELLEBORI. *U. S.* *Extract of Black Hellebore.*

This is prepared, according to the U. S. Pharmacopœia, from Black Hellebore, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum*.)

In consequence, probably, of the injurious influence of heat upon black hellebore, the watery extract prepared by decoction is little if at all stronger

than the root. The process of percolation with cold spirit has, therefore, been adopted in the last edition of the U.S. Pharmacopœia; and, if proper attention be paid to conduct the evaporation at as low a temperature, and with as little exposure to the air as possible, an efficient extract will probably be obtained. It operates as a drastic purge in the dose of twelve or fifteen grains, but is seldom employed.

The former French Codex contained a process for preparing the extract of hellebore, according to the method of Bacher. Two pounds of the root and half a pound of carbonate of potassa are digested, with a moderate heat, for twelve hours, in eight pounds of alcohol of 22° B.; the tincture is strained with expression, the residuum is again digested with eight pounds of white wine for twenty-four hours; the wine is expressed, and having stood four hours to settle is decanted; the liquors are then mixed, and with a gentle heat evaporated to the consistence of an extract. One ounce of this extract, mixed with the same quantity of myrrh, and with ten scruples of the powdered leaves of the *Centaurea benedicta*, and made into pills of one grain each, constitutes the preparation known as the *tonic pills of Bacher*, formerly much used in amenorrhœa and dropsy, and probably not without advantage, especially in the former of these diseases. The dose is from ten to twenty pills during the day. An additional quantity of diluted alcohol might, without disadvantage, be substituted for the wine in the preparation of the extract.

W.

EXTRACTUM HUMULI LUPULI. *Dub.* EXTRACTUM LUPULI. *Lond. Ed. Extract of Hops.*

The *London College* prepares this extract in the manner directed for extract of gentian (see *Extractum Gentianæ*); the *Edinburgh*, in the same manner as extract of logwood (see *Extractum Hæmatoxyli*); and the *Dublin*, according to its general formula for simple extracts. (See p. 933.)

Since the discovery of the fact that the active properties of hops reside chiefly in the lupulin, this extract has not been deemed an eligible preparation, and has been little used. It has the peculiar bitterness of the strobiles, without their aroma. Lupulin may be advantageously substituted for it in all cases in which it was formerly employed. Mr. Brande says, that the average product of one cwt. of hops is forty pounds of the extract. The dose is from ten to thirty grains.

W.

EXTRACTUM HYOSCYAMI. *U. S., Lond., Ed.* SUCCUS SPISATUS HYOSCYAMI. *Dub. Extract of Henbane.*

This is prepared from fresh Henbane Leaves in the manner directed by the U. S. Pharmacopœia for extract of stramonium leaves (see *Extractum Stramonii Foliorum*), by the *London* and *Dublin* for extract of aconite (see *Extractum Aconiti*), and by the *Edinburgh* for extract of hemlock (see *Extractum Conii*).

MM. Solon and Soubeiran have shown that the insoluble matter separated from the expressed juice of henbane by filtering, and that coagulated by heat, are nearly, if not quite, inert; so that the juice may be advantageously clarified before evaporation. (*Amer. Jour. of Pharm.* viii. 228.) Extract of henbane is seldom, if ever, made in this country, being derived chiefly from England. Mr. Brande says, that one cwt. of the fresh herb affords between four and five pounds. M. Recluz obtained about one part from sixteen.

The extract, as it reaches us, is of a dark-olive colour almost black, of a narcotic rather unpleasant odour, and a bitterish, nauseous, slightly saline taste. It retains its softness for a long time; but at the end of three or four

years becomes dry, and exhibits, when broken, small crystals of nitrate of potassa and chloride of sodium. (*Recluz.*) Like all the inspissated juices it is of variable strength, according to its age, the care used in its preparation, and the character of the leaves from which it was procured. (See *Hyoscyamus.*) In its use, therefore, it is advisable to begin with a moderate dose, two or three grains for instance, and gradually to increase the quantity till some effect is experienced, and the degree of efficiency of the particular parcel employed is ascertained. It is usually given in pill. It is sometimes used externally for the same purposes as extract of belladonna.

Off. Prep. Pilulæ Colocyntidis et Hyoscyami, *Ed.*

W.

EXTRACTUM HYOSCYAMI ALCOHOLICUM. U. S. *Alcoholic Extract of Henbane.*

This is prepared, according to the U. S. Pharmacopœia, from Henbane Leaves, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum.*)

The alcoholic extract of henbane, if prepared from recently dried leaves, is thought to be more uniform and more powerful than the inspissated juice or common extract. It is one of the preparations of the French Codex. The dose is one or two grains, to be gradually increased until its effects are obtained.

W.

EXTRACTUM JALAPÆ. U. S., Lond., Dub. *Extract of Jalap.*

This is prepared, according to the U. S. Pharmacopœia, from Jalap, in coarse powder, in the manner directed for extract of Peruvian bark. (See *Extractum Cinchonæ.*)

“Take of Jalap, in powder, *two pounds and a half*; Rectified Spirit *a gallon* [Imperial measure]; Distilled Water *two gallons* [Imperial measure]. Macerate the Jalap in the Spirit for four days, and pour off the tincture. Boil the residue in the Water down to half a gallon. Filter the tincture and decoction separately; then distil the former and evaporate the latter until they thicken. Lastly, mix the extract with the resin, and evaporate to the proper consistence. Let the extract be kept *soft*, fit for forming pills, and *hard*, so that it may be powdered.” *Lond.*

The *Dublin* process is essentially the same as the above.

Jalap contains a considerable quantity of starch, which is extracted by decoction, but left behind when cold water is used as the menstruum. As this principle serves only to impede the filtration or straining, and augment the bulk of the extract, without adding to its virtues, the U. S. process, in which the water is employed at common temperatures, is preferable to the London and Dublin, in which decoction is resorted to. The use both of alcohol and water is necessary, in order to extract all the medicinal qualities of the drug, and they are employed successively, under the impression that the previous removal of the resin by the former facilitates the action of the latter. The use of percolation, as directed by the U. S. Pharmacopœia, enables the cold water to extract the soluble parts without the long maceration which would otherwise be necessary. According to Cadet de Gassicourt, water at ordinary temperatures, and in the old mode, acts so slowly, that fermentation takes place before the active matter is all dissolved. Hence, if the extract is prepared without the use of displacement, the residuum, after the tincture has been decanted, should be digested with water at a heat of about 90° or 100° F., which, while it is insufficient for the solution of the starch, enables the solvent to take up the active matter with sufficient rapidity.

One cwt. of jalap affords, according to Mr. Brande, about fifty pounds of aqueous extract and fifteen of resin. The product of the former is somewhat less by infusion than decoction; and the extract is proportionably stronger.

The extract of jalap is of a dark-brown colour, slightly translucent at the edges, and tenacious when not perfectly dry. It contains the resin and gummy extractive, and, consequently, has all the medical properties of the root; but it is not often exhibited alone, being chiefly used as an ingredient of purgative pills, for which it is adapted by the comparative smallness of its bulk. The dose is from ten to twenty grains, or rather more than half that of jalap.

Off. Prep. Pilulæ Catharticæ Compositæ, *U. S.*; Pulvis Scammonii Compositus, *Lond., Dub.* W.

EXTRACTUM sive RESINA JALAPÆ. *Ed.* *Extract or Resin of Jalap.*

“Take any convenient quantity of Jalap, in moderately fine powder; mix it thoroughly with enough of Rectified Spirit to moisten it well; put it in twelve hours into a percolator, and exhaust the powder with Rectified Spirit; distil off the greater part of the Spirit, and concentrate the residuum over the vapour-bath to a due consistence.” *Ed.*

This process yields the resin of jalap in an impure state. It may be obtained pure by pouring boiling water on the roots, macerating for a day, then cutting them into very thin slices, boiling them three times successively for about ten minutes in water, expressing after each decoction, afterwards boiling them as often and as long in alcohol, and in like manner expressing, finally mixing the tinctures, treating the liquor with animal charcoal, filtering, and evaporating. (*Nativelle, Journ. de Pharm. N. S. i. 228.*) Another mode is to introduce into a displacement instrument, first one part of finely powdered animal charcoal, and afterwards two parts mixed with an equal quantity of powdered jalap, then to pour on alcohol until the liquid which passes equals the jalap, and finally to add to the tincture thus obtained twice its volume of water, so as to precipitate the resin, which is to be washed, and dried. (*Christison's Dispensatory.*) The pure resin is as white as starch, and in doses of from three to five grains was found to purge actively. For practical purposes, however, the Edinburgh preparation is sufficiently pure. It is dark-coloured, brittle, and of a shining fracture.

It is now generally believed, that the resin of jalap is its sole purgative principle, the gummy extractive being diuretic. The *U. S.* or London extract better represents the whole virtues of jalap, and should be preferred when its peculiar hydragogue operation is required. The Edinburgh extract or resin is more powerfully purgative, but is also harsh, and apt to operate painfully. To obviate this effect it is advised that it should be triturated with loaf-sugar, sulphate of potassa, almond emulsion, or other substance calculated to separate its particles. The dose is from four to twelve grains. W.

EXTRACTUM JUGLANDIS. *U. S.* *Extract of Butternut.*

This is prepared from the inner bark of the root of the *Juglans cinerea*, in coarse powder, in the manner directed for extract of gentian. (See *Extractum Gentianæ.*)

Most of this extract kept in the shops is prepared by the country people, who are said to use the bark of the branches, and even the branches them-

selves, instead of the inner bark of the root, as directed by the Pharmacopœia. The heat is also improperly regulated, being applied too vigorously, or continued too long, so that the preparation is often injured. That it should have proved uncertain in the hands of many physicians is, therefore, not a matter of surprise. It should always be prepared by the apothecary, and from the inner bark of the root gathered in May or June.

The extract of butternut is of a black colour, sweetish odour, and bitter astringent taste. In the dose of twenty or thirty grains it acts as a mild cathartic. (See *Juglans*.) W.

EXTRACTUM KRAMERIÆ. U. S., Ed. *Extract of Rhatany.*

This is prepared from Rhatany, in coarse powder (U. S.), or in moderately fine powder (*Ed.*), in the manner directed for extract of gentian. (See *Extractum Gentianæ*.)

In selecting a process for the preparation of this new officinal, it was undoubtedly wise to adopt the mode of displacement, with cold water as the menstruum. (See pages 419 and 420.) It is absolutely necessary to the success of this process, that the root should be well and uniformly comminuted; and the "moderately fine powder" of the Edinburgh Pharmacopœia is, therefore, preferable to the "coarse powder" of our own. The wood of the root yielded to Mr. Procter only 6.8 per cent. of extract, while the bark separated from the wood yielded 33 per cent. As the wood is of difficult pulverization, the inference is obvious, that in powdering the roots, the ligneous portion might be rejected with advantage. (*Am. Journ. of Pharm.* xiv. 270.) As a prolonged exposure of the infusion to the air is attended with the absorption of oxygen, and the production of insoluble apotheme, it is desirable that the evaporation should be conducted rapidly or in a vacuum. There scarcely appears to be occasion, in the case of rhatany, for heating and filtering the infusion before evaporation, the only use of which would be to get rid of albumen, which is not among the recognised ingredients of rhatany.

Very inferior extracts of rhatany are often found in the shops. Such is the South American extract, which is occasionally imported. As the product obtained by decoction is greater than that afforded by the officinal plan, the temptation to substitute the former is not always resisted, although it has been shown to contain nearly 50 per cent. of insoluble matter. A substance was shown us by a respectable apothecary of this city, said to have been imported as extract of rhatany from Europe, which was nearly tasteless, and was plausibly conjectured to be the dried coagulated matter of old tincture of kino.

Extract of rhatany should have a reddish-brown colour, a smooth shining fracture, and a very astringent taste; and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed. The dose is from ten to twenty grains.

Off. Prep. Syrupus Kramerie, U. S.

W.

EXTRACTUM LACTUCÆ. Lond. *Extract of Lettuce.*

This extract is prepared by the *London College* from fresh Lettuce leaves in the same manner as extract of aconite. (See *Extractum Aconiti*.)

The extract of lettuce has been retained by the *London College*, though the lettuce itself from which it is prepared has been rejected. Its claims to favourable notice are at least very questionable. Consisting chiefly of the common sap of the plant, which is inert, with a variable, but always small

proportion of the milky secretion, on which the activity of lettuce depends, it is at best a feeble and uncertain preparation. Lactucarium possesses all its virtues, with more strength and uniformity of action. The dose of the extract is from five to fifteen grains. W.

EXTRACTUM NUCIS VOMICÆ. *U. S., Ed., Dub. Extract of Nux Vomica.*

"Take of Nux Vomica *a pound*; Alcohol *a sufficient quantity*. Expose the Nux Vomica to steam till it is softened; then, having sliced and dried it, grind it into powder. Introduce it into an apparatus for displacement, and pour Alcohol upon it gradually until the liquid passes without bitterness. Distil off the greater part of the alcohol from the filtered liquor, and evaporate the residue to the proper consistence." *U. S.*

The *Edinburgh College* treats the Nux Vomica in the same manner, grinding it to powder in a coffee-mill; then exhausts it with rectified spirit, either by percolation or repeated decoction; and completes the process as above directed.

"Take of Nux Vomica, rasped, *eight ounces*; Proof Spirit *two pints*. Digest in a close vessel for three days; filter the liquor, and express the remainder by a press. Add to the residue one pint and a half of Proof Spirit, digest for three days, and express. Mix the liquors, and having reduced them by distillation to one-fourth, evaporate to a proper consistence." *Dub.*

This extract is an active preparation of nux vomica, though not always of uniform strength, owing to the variable proportion of strychnia in the substance from which it is prepared. M. Recluz obtained from sixteen ounces of the nux vomica, the average product of one ounce and a quarter. The dose of the extract is from half a grain to two grains, to be repeated three times a day. W.

EXTRACTUM OPII. *Ed.* EXTRACTUM OPII PURIFICATUM. *Lond.* EXTRACTUM OPII AQUOSUM. *Dub. Extract of Opium.*

"Take of Opium *one pound*; Water *five pints* [Imperial measure]. Cut the Opium into small fragments, macerate it for twenty-four hours in a pint of Water, break down the fragments with the hand; express the liquid with pretty strong pressure; break down the residuum again in another pint of the Water, let it macerate for twenty-four hours, and express the liquid; repeat the maceration and expression in the same way till the water is all used. Filter the successive infusions as they are made, passing them through the same filter; unite and evaporate them in the vapour-bath to the due consistence." *Ed.*

"Take of Opium, sliced, *twenty ounces*; Distilled Water *a gallon* [Imperial measure]. Add a little of the Water to the Opium, and macerate for twelve hours that it may become soft; then, adding gradually the remainder of the Water, rub them until they are thoroughly mixed, and set the mixture by that the dregs may subside; lastly, strain the liquor, and evaporate it to a proper consistence." *Lond.*

"Take of Opium, sliced, *two ounces*; Boiling Water *a pint*. Rub the Opium with the Water for ten minutes, and, after a short interval, pour off the liquor. Triturate the remaining Opium with an equal quantity of boiling Water, for the same length of time, and pour off the liquor as before. Repeat the trituration a third time; then mix the liquors, and expose the mixture to the air for two days in an open vessel. Lastly, filter through linen, and evaporate the filtered liquor slowly to the consistence of an extract." *Dub.*

Of these processes, that of the *Edinburgh* or *Dublin College* should be

preferred. But we can discover no advantage which either preparation has over opium itself. Though the dose may be somewhat smaller, yet that of opium is sufficiently small; and if there be any distinct principle in this drug which modifies in an unpleasant manner the action of the morphia, it is not left behind in the preparation of the watery extract. Nor has this preparation the advantage of greater uniformity; as the gum, extractive, &c., taken up by the water, bear no fixed proportion to the anodyne principle. It is highly probable, moreover, that the opium is not completely exhausted by either process. It certainly is not by that of the London College; for morphia may be extracted from the residuum of the operation. (*Brande.*) In the preparation, therefore, of the extract of opium, there is a loss of time and of active matter, without any equivalent gain; and there is the further disadvantage, that, as the extract does not possess equally with opium those external characters by which its quality may be decided, it is more liable to adulteration. We should, therefore, in every instance, prefer opium to the extract; but it is necessary that the former should be selected of good quality, and should be freed from all adhering extraneous matters.

Under the impression that the stimulating and unpleasant effects of opium are owing to the narcotina, it has been proposed to separate this principle by submitting the extract to the operation of ether, which dissolves the narcotina and leaves the morphia with the other ingredients. Robiquet employed cold ether; but M. Dublanc, convinced that the whole of the narcotina was not thus extracted proposed the following plan. "Take of watery extract of opium 16 ounces; dissolve it in 8 ounces of distilled water; introduce the solution into the water-bath of a still; pour upon it 104 ounces of pure ether; distil off 24 ounces of the ether; take apart the apparatus and decant the ether which floats on the top of the extract; wash the latter while hot with the distilled ether; concentrate the residual matter, dissolve it in distilled water, filter the solution, and evaporate to a proper consistence." It is very doubtful, however, whether any useful end is gained by this expensive operation, as it is not by any means conclusively settled that narcotina does in fact produce the unpleasant effects which have been attributed to it; and even admitting the fact, the preparations of morphia, which are of uniform strength, are greatly preferable to the *denarcotized extract*.

The dose of the extract of opium prepared by the Edinburgh or Dublin process is about one-half that of opium itself. The London extract, according to Brande, is never stronger, and is sometimes weaker than opium. Recluz obtained from sixteen ounces of opium an average product of nine ounces by hot water and six by cold.

Off. Prep. Vinum Opii, *Lond.*

W.

EXTRACTUM PAPAVERIS. *Lond., Ed. Extract of Poppy.*

"Take of Poppy [capsules], freed from their seeds, and bruised, *fifteen ounces*; Boiling Distilled Water *a gallon* [Imperial measure]. Macerate for twenty-four hours, then boil down to four pints, strain the liquor while hot, and evaporate it to a proper consistence." *Lond.*

The *Edinburgh* process corresponds closely with the above; boiling water simply, instead of boiling distilled water being employed, and evaporation over the vapour-bath directed.

Mr. Brande observes in relation to this extract, that if prepared over the open fire it is often nearly inert. He states, moreover, that it is apt to be of a troublesome consistence, too hard to be formed into pills, and too tough to be pulverized; and advises that it should always be carefully dried till it becomes sufficiently brittle to admit of being reduced to powder. One cwt.

of the capsules, without the seeds, yields, according to this author, the average product of 35 pounds of extract.

This preparation is little used in the United States. It possesses the virtues of opium, but is much inferior and less uniform in strength. The dose is from five to ten grains. W.

EXTRACTUM PAREIRÆ. *Lond., Ed. Extract of Pareira Brava.*

This is prepared by the *London College* from bruised Pareira Brava in the manner directed for extract of gentian. (See *Extractum Gentianæ*.)

The *Edinburgh College* directs the root to be cut into small chips, dried thoroughly with a gentle heat, then reduced to a moderately fine powder, and treated as directed for the extract of gentian.

The dose is from ten grains to half a drachm. W.

EXTRACTUM PODOPHYLLI. *U.S. Extract of May-apple.*

This is prepared from the root of *Podophyllum peltatum*, in coarse powder, in the manner directed for the extract of Peruvian bark. (See *Extractum Cinchonæ*.)

It is possessed of the purgative properties of the root, and may be given in the dose of from five to fifteen grains, but is little employed. It might be substituted in all cases for the extract of jalap. W.

EXTRACTUM QUASSIÆ. *U.S., Ed. Extract of Quassia.*

This is prepared, according to the U. S. Pharmacopœia, from the raspings of quassia, in the manner directed for the extract of gentian. (See *Extractum Gentianæ*.)

The *Edinburgh College* prepares it by cutting the quassia into small chips, drying it thoroughly with a gentle heat, reducing it to a moderately fine powder, and proceeding as directed for the extract of gentian.

According to M. Recluz, sixteen ounces of quassia yield by infusion in water seven drachms of extract; by maceration in alcohol of 19° Baumé, two ounces five drachms and a half. The difference between these quantities is so great that we suspect some mistake in the table of the *Dictionnaire des Drogues* from which we quote.

The extract of quassia is dark-brown or black, and excessively bitter. It is apt to become dry and disposed to crumble by time. It concentrates a greater amount of tonic power within a given weight than any other extract of the simple bitters; and may, therefore, be given with great advantage in cases in which it is desirable to administer this class of substances in as small a bulk, and with as little inconvenience to the patient as possible. The dose is about five grains, to be given in the form of pill. W.

EXTRACTUM QUERCÛS. *Dub. Extract of Oak Bark.*

This is prepared from the bark of the *Quercus Robur*, according to the general formula given by the *Dublin College* for the preparation of the simple extracts. (See page 933.)

The *Dublin College* alone orders this preparation, which may be considered as quite superfluous. The dose is from ten grains to a drachm.

EXTRACTUM RHEI. *Lond., Ed., Dub. Extract of Rhubarb.*

"Take of Rhubarb, in powder, fifteen ounces; Proof Spirit a pint [Imperial measure]; Distilled Water seven pints [Imp. meas.]. Macerate for four days with a gentle heat, then strain, and set the liquor by that the dregs may subside. Pour off the clear liquor, and evaporate it to the proper consistence." *Lond.*

The *Dublin College* employs a *pound* of Rhubarb, a *pint* of Proof Spirit, and *seven pints* of Water; and proceeds as above.

“Take of Rhubarb *one pound*; Water *five pints* [Imp. meas.]; cut the Rhubarb into small fragments, macerate it for twenty-four hours in three pints of the Water, filter the liquor through a cloth, and express it with the hands or otherwise moderately; macerate the residuum with the rest of the Water for twelve hours at least, filter the liquor with the same cloth as before, and express the residuum strongly. The liquors, filtered again if necessary, are then to be evaporated together to a proper consistence in the vapour-bath. The extract, however, is obtained of finer quality by evaporation in a vacuum with a gentle heat.” *Ed.*

Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation is performed with great care and with a very moderate heat, it is certain that the purgative principle is, to a greater or less extent, injured or dissipated in the process; and the extract may thus become even less efficient than the root. Among other consequences which result from the boiling temperature, is the formation of a compound of the tannin and starch which is insoluble in cold water, and upon its precipitation probably carries with it a portion of the purgative principle. There is, moreover, reason to believe that this principle is volatilizable by heat, and that a portion of it escapes with the vapour. This extract may, therefore, be very well dispensed with. It is not directed by the United States Pharmacopœia. The only advantage, if it be one, which it possesses over powdered rhubarb is, that it may be given in solution; and the same object may be accomplished by employing the root itself in the state of infusion. The dose of the extract is from ten to thirty grains.

Off. Prep. Pilulæ Rhei et Ferri, *Ed.*

W.

EXTRACTUM RUTÆ. *Dub.* *Extract of Rue.*

This is prepared by the *Dublin College* from the herb, in the manner directed for the preparation of the simple extracts. (See page 933.)

The volatile oil, upon which the stimulant and antispasmodic properties of rue depend, is driven off in the preparation of the extract, which, therefore, answers no other purpose than that of a bitter tonic; and even in this respect is inferior to the other bitter extracts. It is not used in this country. The dose is from ten to twenty grains.

W.

SUCCUS SPISSATUS SAMBUCI. *Dub.* *Inspissated Juice of Elder.*

This is prepared by the *Dublin College* from fresh ripe elder berries in the same manner with the inspissated juice of aconite. (See *Extractum Aconiti*.)

The elder berries employed in Europe are those of the *Sambucus nigra*; but the berries of the *Sambucus Canadensis*, which is a native of this country, will answer equally well. For the uses of this extract the reader is referred to the article *Sambucus* in the *Materia Medica*. W.

EXTRACTUM SARSAPARILLÆ. *U. S., Dub.* EXTRACTUM SARZÆ. *Lond.* *Extract of Sarsaparilla.*

The *U. S. Pharmacopœia* prepares this extract from sarsaparilla, in coarse powder, in the manner directed for alcoholic extract of aconite. (See *Extractum Aconiti Alcoholicum*.)

“Take of Sarsaparilla root, sliced, a *pound*; Boiling Water a *gallon*. Macerate for twenty-four hours, and boil down to four pints; then strain the liquor while hot, and evaporate to the proper consistence.” *Dub.*

The *London College* prepares the extract in the manner directed for extract of gentian. (See *Extractum Gentianæ.*)

The extract prepared according to the London and Dublin processes can have little or no effect upon the system; as the active matter of sarsaparilla is either destroyed by chemical change or driven off at the heat of boiling water. Besides, it appears from the experiments of Hancock and others, that water, unless in very large proportion, is incapable of exhausting the root; and waste would be incurred, even admitting that the extract possessed some efficiency. Very different quantities have been obtained from different varieties of sarsaparilla, and even from different parcels of the same variety; but as the matter taken up by boiling water consists chiefly of starch, no inference as to the relative value of any particular specimen of the root can be drawn from a knowledge of the quantity of extract which it is capable of affording. From ten grains to a drachm of this preparation may be given for a dose.

The *spirituous extract* of the U. S. Pharmacopœia, which is the same as that of the French Codex, contains the active matter of the root. Diluted alcohol extracts all the virtues of sarsaparilla, leaving the inert fecula which encumbers the extract obtained by decoction; while the temperature requisite for the concentration of the tincture is insufficient to destroy the active principle. M. Beral obtained from 32 ounces of sarsaparilla about 4 ounces of extract by maceration with diluted alcohol. As the product of this operation is about one-eighth of the sarsaparilla employed, a drachm of the extract represents an ounce of the root. From ten to twenty grains of it may be given three or four times a day. We have ascertained by actual observation that it possesses in a high degree the acrid taste of sarsaparilla.

W.

EXTRACTUM SARSAPARILLÆ FLUIDUM. *Dub.* EXTRACTUM SARZÆ FLUIDUM. *Ed.* *Fluid Extract of Sarsaparilla.*

“Take of Sarza in chips *one pound*; Boiling Water *six pints* [Imperial measure]. Digest the root for two hours in four pints of the Water; take it out, bruise it, replace it, and boil for two hours; filter and squeeze out the liquid; boil the residuum in the remaining two pints of Water, and filter and squeeze out this liquor also; evaporate the united liquors to the consistence of thin syrup; add, when the product is cool, as much Rectified Spirit as will make in all sixteen fluidounces. Filter. This fluid extract may be aromatized with volatile oils or warm aromatics.” *Ed.*

“Take of the Root of Sarsaparilla, sliced, *a pound*; Water *twelve pints*. Boil them together for an hour, and pour off the liquor; then add twelve pints of water, and boil and decant as before. Express the liquor strongly from the residuary matter, and having mixed the decoctions, set the mixture by that the dregs may subside; then evaporate by continued boiling to thirty ounces [fluidounces], and add two ounces [fluidounces] of Rectified Spirit.” *Dub.*

It is to be regretted, that this preparation is not more in conformity with our present knowledge in relation to the pharmaceutical management of sarsaparilla. There can be little doubt, we think, as to the almost total inefficiency of the fluid extract of the Edinburgh and Dublin Colleges. We should ourselves prefer the solid extract, prepared according to the U. S. formula, to any concentrated liquid preparation; as we cannot be certain that the active principle is held in solution by a very small proportion of water, and if it be merely suspended, there may be a risk that due agitation may not always be practised in dispensing and administering the medicine. But

if the popular inclination to this mode of preparation must be gratified, we should give a decided preference to the following formula of William Hodgson, Jun., over any other which we have seen.

“Take of Sarsaparilla Root, bruised, *sixteen ounces*; Liquorice Root, bruised, Guaiacum Wood, rasped, Bark of Sassafras Root, each, *two ounces*; Mezereon *six drachms*; Diluted Alcohol *eight pints*. Digest for fourteen days at a common temperature; then strain, express, and filter. Evaporate the tincture in a water-bath to twelve fluidounces; then add eight ounces of white sugar, and remove from the fire as soon as the sugar is dissolved.” (*Journ. of the Phil. Col. of Pharm.* ii. 285.)

Mr. Hodgson observes, that during the process a small quantity of resin separates, and adheres to the sides of the vessel, apparently derived from the guaiacum wood. The advantages of this process are, that by means of the alcohol all the virtues of the root are extracted, while the low temperature required in its evaporation is not sufficient to impair these virtues. The preparation has been used in Philadelphia with great apparent advantage in secondary syphilis. The dose is a fluidrachm, equivalent to a drachm of the root, three or four times a day. W.

EXTRACTUM *sive* RESINA SCAMMONII. *Ed.* *Extract or Resin of Scammony.*

“Take *any convenient quantity* of Scammony in fine powder; boil it in successive portions of Proof Spirit till the Spirit ceases to dissolve any thing; filter; distil the liquid till little but water passes over. Then pour away the watery solution from the resin at the bottom; agitate the resin with successive portions of boiling water till it is well washed; and lastly, dry it at a temperature not exceeding 240°.” *Ed.*

The only advantage of this preparation is that it separates the active matter of scammony from the impurities with which the drug is almost always adulterated. When pure virgin scammony can be procured the extract is unnecessary. Prepared according to the above process, the resin is of a dirty greenish-brown colour, with a feeble odour and taste of scammony, and is very soluble in ether, alcohol, and boiling proof-spirit. When purified with animal charcoal it has a pale-brownish yellow colour, without odour and taste; but retains its purgative property. When rubbed with unskimmed milk it forms a uniform emulsion undistinguishable from rich milk itself. This is an excellent mode of administration. The resin should always be given either rubbed up with some mild powder, or in emulsion. The dose is from five to twelve grains.

Off. Prep. Mistura Scammonii, *Ed.*

W.

EXTRACTUM SPARTII SCOPARII. *Dub.* *Extract of Broom Tops.*

This is prepared from the tops of the *Cytisus Scoparius*, according to the general formula of the *Dublin College* for the preparation of their simple extracts. (See page 933.)

It has laxative and diuretic properties; but is not employed in this country and seldom in Europe. The dose is from thirty grains to a drachm. W.

EXTRACTUM STRAMONII FOLIORUM. *U.S.* *Extract of Stramonium Leaves.*

“Take of Stramonium Leaves *a pound*. Bruise them in a stone mortar, sprinkling on them a little water; then express the juice, and, having heated it to the boiling point, strain and evaporate to the proper consistence.” *U. S.*

Like all the other inspissated narcotic juices, this is an uncertain preparation, varying in strength according to the care used in conducting the process, and the season at which the leaves are collected. The reader will find at page 933 and in the preliminary observations on the Extracts, some general rules which will be found useful in conducting this process, and all those of which it is the officinal type. The insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, may be advantageously rejected; as, according to the observations of MM. Solon and Soubeiran, they are nearly or quite inert. M. Recluz obtained half an ounce of the extract from sixteen ounces of the leaves. The dose is a grain night and morning to be gradually increased till it affects the system. W.

EXTRACTUM STRAMONII SEMINIS. U.S. EXTRACTUM STRAMONII. *Lond., Ed., Dub. Extract of Stramonium Seed.*

"Take of Stramonium Seed, ground into powder, *a pound*; Diluted Alcohol *a sufficient quantity*. Having rubbed the powder with *half a pint* of Diluted Alcohol, introduce the mixture into an apparatus for displacement, and pour upon it gradually Diluted Alcohol till the liquid passes colourless. Distil off the Alcohol from the filtered liquor, and evaporate the residue to the proper consistence." U.S.

"Take of Seeds of Stramonium *any convenient quantity*; grind them well in a coffee-mill. Rub the powder into a thick mass with Proof Spirit; put the pulp into a percolator, and transmit Proof Spirit till it passes colourless; distil off the spirit, and evaporate what remains in the vapour-bath to a proper consistence." Ed.

"Take of Stramonium seeds *fifteen ounces*; Boiling Distilled Water *a gallon* [Imperial measure]. Macerate for four hours in a covered vessel near the fire; then take out the Seeds, and, after having bruised them in a stone mortar, return them to the liquor. Boil down to four pints [Imp. measure], and strain the decoction while hot. Finally, evaporate to the proper consistence." Lond.

The *Dublin College* gives the same process as the London; but directs *a pound* of the seeds, and a *wine-gallon* of undistilled water.

The U. S. and Edinburgh processes, which may be considered identical, are preferable to the London and Dublin; as the seeds yield their virtues more freely to spirit than to water alone. According to the table of Recluz, sixteen ounces of the seeds afford two ounces and two drachms of extract by maceration in diluted alcohol, and one ounce and a half by decoction. The dose to begin with is a quarter or half a grain twice a day, to be gradually increased. W.

EXTRACTUM TARAXACI. U.S., Lond., Ed., Dub. *Extract of Dandelion.*

This is prepared, according to the U.S. Pharmacopœia, from the fresh bruised root of the *Leontodon Taraxacum*, in the manner directed for extract of logwood. (See *Extractum Hæmatoxyli*.)

The *London College* prepares it in the manner directed for extract of gentian (see *Extractum Gentianæ*); the *Edinburgh*, from *a pound* of the fresh root and *a gallon* [Imperial measure] of boiling water, as directed for the extract of poppy heads (see *Extractum Papaveris*). The *Dublin College* employs both the herb and root, and proceeds according to the general formula for the simple extracts. (See page 933.)

This extract is undoubtedly stronger, prepared from the root alone than from the whole plant. Nor is it a matter of indifference at what season the

root may be collected. The juice obtained from it by expression in the spring is thin, watery, and of feeble flavour; in the latter part of summer, and in autumn, thick, opaque, cream-coloured, very bitter, and abundant, amounting to one-third or one-half the weight of the root. It may be collected in August, and afterwards until severe frost. According to Mr. Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the growing root. It is probable that an extract prepared by the inspissation of this juice, would be found much more efficient than that prepared in the usual way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure, during evaporation, is said to cause a change of the bitterness of the juice into sweetness, which is a sign of inferiority. As found in the shops, the extract is dark-coloured, sweet, and in all probability nearly inert. Mr. Houlton took more than an ounce of it in a day, without any sensible effect. (Houlton and Squire, *Pharm. Journ. and Transact.* i. 421.) Mr. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained in November, and the least in April and May.

This extract deteriorates by keeping, and should, therefore, be renewed annually. It is most conveniently given dissolved in cinnamon or mint water. The dose is from a scruple to a drachm three times a day. W.

EXTRACTUM UVÆ URSI. *Lond. Extract of Uva Ursi.*

The *London College* prepares this extract in the manner directed for extract of gentian. (See *Extractum Gentianæ*.)

The dose is from five to thirty grains.

W.

FERRUM.

Preparations of Iron.

FERRI ACETAS. *Dub. Acetate of Iron.*

“Take of Carbonate of Iron *one part*; Acetic Acid *six parts*. Digest for three days and filter.” *Dub.*

As the carbonate of iron of the Dublin Pharmacopœia (the U. S. subcarbonate and the London sesquioxide) consists mainly of sesquioxide of iron, associated with a little carbonate of protoxide, it is evident that this preparation is an aqueous solution of the acetate of sesquioxide of iron, containing a small proportion of the acetate of the protoxide. From comparative experiments made by Dr. Perceval of Dublin, it was found that of ten grains of the following ferruginous preparations digested in two drachms of acetic acid, sp. gr. 1.065, half a grain was dissolved of the scales of iron, one and a quarter grains of the red oxide (sesquioxide obtained by strong calcination), three and a quarter of iron filings, and the whole of the so-called carbonate. It was on account of the entire solubility of the latter preparation that it was selected for solution in the acetic acid.

Properties, &c. This solution has a deep red colour, and an acid and strongly chalybeate taste. When exposed to heat it yields acetic acid. It possesses the general medical properties of the preparations of iron. The dose is from ten to twenty-five drops, taken in water. It is not used in this country.

B.

FERRI ACETATIS TINCTURA. *Dub. Tincture of Acetate of Iron.*

“Take of Acetate of Potassa *two parts*; Sulphate of Iron *one part*; Rectified Spirit *twenty-six parts*. Rub the Acetate of Potassa and Sulphate of Iron together in an earthenware mortar, until they unite into a mass. Dry this with a medium heat, and triturate it with the Spirit. Digest the mixture in a well stopped bottle for seven days, shaking it occasionally. Lastly, pour off the tincture from the sediment, and preserve it in a well stopped bottle.” *Dub.*

This preparation was introduced into the Dublin Pharmacopœia by Dr. Perceval. In the process, a double decomposition takes place between the salts employed, resulting in the formation of the acetate of iron which dissolves in the spirit, and sulphate of potassa which remains behind, being insoluble in that menstruum. The tincture also contains a portion of acetate of potassa; more of this salt being employed than is necessary to decompose the sulphate of iron.

Properties. This tincture is a transparent liquid, of a deep claret colour, and strong chalybeate taste. When evaporated to dryness, it yields a saline matter, which is whitish from the presence of acetate of potassa. It is extremely liable to spontaneous decomposition, and is decomposed by the alkalis and their carbonates, the strong acids, and astringent vegetable infusions.

Medical Properties and Uses. This preparation is represented to be an agreeable chalybeate; but it possesses no particular virtue, which can give it any advantage over other medicines of the same class. The dose is from thirty drops to a teaspoonful, mixed with water or some other convenient vehicle.

B.

TINCTURA ACETATIS FERRI CUM ALCOHOL. *Dub. Tincture of Acetate of Iron with Alcohol.*

“Take of Sulphate of Iron, Acetate of Potassa, each, *an ounce*; Alcohol *two pints*. Rub the Acetate of Potassa and Sulphate of Iron together in an earthenware mortar, until they unite into a soft mass; then dry this with a medium heat, and as soon as it has grown cold, triturate it with the alcohol. Digest the mixture in a well stopped bottle for twenty-four hours, shaking it occasionally. Lastly, pour off the clear tincture from the sediment, and keep it in a well stopped bottle.” *Dub.*

This formula is nearly the same with the last; the points of difference being that equal weights of the saline materials are employed, and the menstruum is the alcohol of the Dublin College, and not rectified spirit. The double decomposition takes place as in the preceding preparation, and with the same results; but here, instead of there being an excess of acetate of potassa to enter into the tincture, there is an excess of sulphate of iron. The acetate of iron formed is a mixture of the acetates of the protoxide and sesquioxide; but the latter only is soluble in the strong alcohol of the Dublin College. Hence this tincture may be viewed as an alcoholic solution of the acetate of the sesquioxide of iron. It is necessary here not to confound the Dublin “alcohol,” which has the sp. gr. 0·810, with the U. S. “alcohol,” which corresponds with the rectified spirit of the British Colleges.

This preparation is stronger, and less liable to spontaneous decomposition than the preceding; while its sensible and medical properties are nearly the same. The dose is from twenty drops to a teaspoonful. A fluidounce of it, when evaporated, yields ten grains of a crimson-coloured extract, which

at first has the consistency of wax, but afterwards, when dried, is transparent. It is not easy to perceive the motive of the Dublin College for having two spirituous preparations of the acetate of iron. B.

FERRI CARBONAS SACCHARATUM. *Ed. Saccharine Carbonate of Iron.*

“Take of Sulphate of Iron *four ounces*; Carbonate of Soda *five ounces*; Pure Sugar *two ounces*; Water *four pints* [Imperial measure]. Dissolve the Sulphate and Carbonate, each, in two pints of the Water; add the solutions and mix them; collect the precipitate on a cloth filter, and immediately wash it with cold water, squeeze out as much of the water as possible, and without delay triturate the pulp which remains with the Sugar previously in fine powder. Dry the mixture at a temperature not much above 120°.” *Ed.*

When solutions of sulphate of iron and carbonate of soda are mixed together, there are formed, by double decomposition, sulphate of soda which remains in solution, and carbonate of protoxide of iron which falls as a pale bluish precipitate. This precipitate begins immediately to alter in nature by the absorption of oxygen, and, if washed and dried in the ordinary way, becomes sesquioxide of iron, associated with a small quantity of the carbonate of the protoxide which has escaped change; in other words, it is converted into the subcarbonate of iron of the U. S. Pharmacopœia. (See *Ferri Subcarbonas*.) As the preparations of iron containing the protoxide are most esteemed, the change which this precipitate undergoes was always matter of regret, and various attempts were made to prevent it. Now saccharine matter has been ascertained to possess the property of preventing this change, and its power is brought into play in the preparation under consideration, for preventing the protoxide of iron of the carbonate as first precipitated from passing into sesquioxide, with loss of carbonic acid.

It appears that Dr. Becker, a German physician, first suggested the use of saccharine matter as a means of protection against the absorption of oxygen, and that the idea was carried out by Klauer, a German chemist, who first made the saccharine carbonate of iron. When sugar is used in the way directed in the above formula, the prevention of oxidation is not complete; for an absorption of oxygen takes place to a partial extent during the washing and squeezing of the precipitate, which are performed before the admixture with the sugar. The protection from oxidation is much more complete, when the materials and product of this process are maintained constantly in contact with saccharine matter, by using weak syrup both for dissolving the salts and for washing the precipitate, after the improved method of Vallet, of Paris. This improved method of proceeding, is adopted for forming the U. S. pills of carbonate of iron, or Vallet's ferruginous pills. (See *Pilulæ Ferri Carbonatis*.)

Saccharine carbonate of iron is a grayish-green powder, permanent in the air, possessing a sweet and strongly chalybeate taste, and wholly and readily soluble in muriatic acid, with brisk effervescence. Its composition is not well made out. According to the Edinburgh Pharmacopœia, it consists of “carbonate of protoxide of iron in an undetermined state of combination with sugar and sesquioxide of iron.” The presence of sesquioxide of iron is a defect, which is avoided in Vallet's ferruginous pills.

Medical Properties. This preparation forms an excellent chalybeate, possessing the advantages of having nearly all the iron in it in the state of protoxide, and of being readily soluble in acids. It is much more active

than the subcarbonate of iron, and must be used in a smaller dose. It is, however, inferior to Vallet's ferruginous mass, in the preparation of which the anti-oxidating influence of saccharine matter is more fully applied. The dose of the saccharine carbonate of iron is from five to thirty grains given in the form of pill.

Off. Prep. Pilulæ Ferri Carbonatis, *Ed.* B.

FERRI ET POTASSÆ TARTRAS. *U.S.* FERRI POTASSIO-TARTRAS. *Lond.* FERRUM TARTARIZATUM. *Ed.* FERRI TARTARUM. *Dub.* Tartrate of Iron and Potassa. Tartarized Iron.

"Take of Subcarbonate of Iron *three ounces*; Muriatic Acid *ten fluid-ounces*; Solution of Potassa *five pints and a half*; Bitartrate of Potassa *seven ounces and a half*; Distilled Water *a gallon and a half*. Mix the Subcarbonate of Iron with the Muriatic Acid, and digest for two hours; then pour the solution into a gallon of the Distilled Water, set aside for an hour, and pour off the supernatant liquor. To this add the solution of Potassa, wash the precipitate which is formed frequently with water, and, while it is yet moist, mix it with the Bitartrate of Potassa and half a gallon of the Distilled Water. Keep the mixture at the temperature of 140° for thirty hours, frequently stirring; then filter the solution, and evaporate by means of a water-bath, at the same temperature, to dryness." *U.S.*

"Take of Sesquioxide [Subcarbonate] of Iron *three ounces*; Hydrochloric [Muriatic] Acid *half a pint* [Imperial measure]; Solution of Potassa *four pints and a half* or *a sufficient quantity*; Bitartrate of Potassa *eleven ounces and a half*; Solution of Sesquicarbonate of Ammonia *a pint* or *a sufficient quantity*; Distilled Water *three gallons* [Imp. meas.]. Mix the Sesquioxide of Iron with the Acid, and digest for two hours in a sand-bath. To these add two gallons of the Water, and set aside for an hour; then pour off the supernatant liquor. The Solution of Potassa being added, wash what is precipitated frequently with water, and, while moist, boil it with the Bitartrate of Potassa, previously mixed with a gallon of the Water. If the liquor should be acid when tried by litmus, drop into it the Solution of Sesquicarbonate of Ammonia until it is saturated. Lastly, strain the liquor, and evaporate it with a gentle heat, so that the salt may remain dry." *Lond.*

"Take of Sulphate of Iron *five ounces*; Bitartrate of Potash *five ounces and one drachm*; Carbonate of Ammonia, in fine powder, *a sufficiency*. Prepare the Rust of Iron from the Sulphate as directed under Ferrugo, and without drying it. Mix the pulpy mass with four pints [Imperial measure] of Water; add the Bitartrate; boil till the Rust of Iron is dissolved; let the solution cool; pour off the clear liquid, and add to this the Carbonate of Ammonia so long as it occasions effervescence. Concentrate the liquid over the vapour-bath to the consistence of a thick extract, or till the residuum becomes on cooling a firm solid, which must be preserved in well closed vessels." *Ed.*

"Take of thin Iron Wire *one part*; Bitartrate of Potassa, in very fine powder, *four parts*; Distilled Water *eight parts* or *a sufficient quantity*. Mix them together, and expose them to the air for fifteen days, in a wide vessel. Stir the mixture occasionally, and keep it constantly moist by the daily addition of water, taking care that the iron shall not be entirely covered by the water. Lastly, boil the product in a sufficient quantity of water, and, having filtered the liquor, evaporate it to dryness over a water-bath. Keep the Tartar of Iron in a well stopped bottle." *Dub.*

The object of these processes is to combine the excess of acid in the

bitartrate of potassa with sesquioxide of iron. The processes of the U. S., London, and Edinburgh Pharmacopœias are essentially the same, being that of Soubeiran with modifications. In Soubeiran's process, the moist hydrated sesquioxide of iron is dissolved to saturation in a mixture of one part of cream of tartar and six of water; and the solution obtained is filtered and evaporated to dryness by a gentle heat. In the processes of the U. S. and London Pharmacopœias, the moist sesquioxide is obtained by precipitating the sesquichloride (formed by dissolving the subcarbonate in muriatic acid) by means of the officinal solution of potassa. Three eqs. of potassa and one of sesquichloride of iron are decomposed, and there are formed three eqs. of chloride of potassium which remain in solution, and one eq. of sesquioxide of iron which precipitates in the hydrated state, ($3\text{KO} + \text{Fe}_2\text{Cl}_3 = 3\text{KCl} + \text{Fe}_2\text{O}_3$). In the Edinburgh process the sesquioxide is obtained, as directed under Ferrugo, by precipitating the tersulphate of the sesquioxide by ammonia; but as one-fourth more sulphate of iron is directed to be converted into sesquioxide than in the Ferrugo formula, it will be found practically inconvenient to increase the quantity of the other materials in the same proportion. The sesquioxide, obtained in either way, is heated or boiled, while yet in the moist state, with a mixture of cream of tartar and water, in which it dissolves. The solution thus obtained contains the tartrate of iron and potassa, and if it should prove acid, the London and Edinburgh Pharmacopœias direct that it be rendered neutral by the addition of carbonate of ammonia. The solution is now filtered and evaporated to dryness. When carbonate of ammonia is added to the solution, it is to be presumed that the resulting salt will contain a little tartrate of ammonia. In the London formula the quantity of cream of tartar taken is excessive, and the water used inconveniently large. Some of the cream of tartar is not dissolved in the water, and that which is dissolved is not fully saturated by sesquioxide, from deficiency of the latter. It is better to have, as in the U. S. formula, an excess of the oxide; for then the cream of tartar is fully saturated, and the solution does not require the addition of carbonate of ammonia to render it neutral.

The formula of the U. S. Pharmacopœia is that recommended by Mr. Wm. Procter, Jun., of this city, founded on the results of Soubeiran and Capitaine. It is superior to the London process, not only in avoiding an excess of water, and the necessity of adding carbonate of ammonia, which introduces an impurity into the preparation, but in substituting the temperature of 140° instead of that of ebullition for promoting the solution of the oxide in the cream of tartar and water. Mr. Procter finds that this temperature, which is recommended by Soubeiran and Capitaine, causes the sesquioxide of iron to be taken up in larger quantity than when ebullition is employed. (See Mr. Procter's paper on the Tartrate of Iron and Potassa, *Amer. Journ. of Pharm.* xii. 188.)

In the *Dublin* process metallic iron is employed. By the combined action of air and water it is converted into sesquioxide, which unites with the cream of tartar to form the double salt. This process consumes much time, and is now superseded by that of Soubeiran.

The wine of iron (*Vinum Ferri*), having been dismissed from the London Pharmacopœia of 1836, is no longer officinal in any of the Pharmacopœias commented on in this work. Yet, as it is sometimes prescribed, it may be well to notice it in this place. The old process for making it was to macerate iron filings in wine. The French Codex, in which this plan is adopted, directs it to be made by macerating for six days in a matrass, an ounce of pure iron filings in thirty-two ounces of good white wine;

stirring from time to time, and afterwards decanting and filtering the liquid. In the dismissed London formula a drachm of iron filings was mixed with six drachms of cream of tartar, and oxidized by exposure to air and moisture for six weeks, so as ultimately to form the double tartrate of iron and potassa, with excess of cream of tartar. This was then dried by a gentle heat, rubbed to powder, dissolved in thirty fluidounces of distilled water, the solution filtered, and finally mixed with twenty fluidounces of proof spirit. When this preparation is made by macerating iron filings in wine, a tartrate of iron and potassa may be supposed to be formed, by means of the tartar present in wine; but as this substance is present in variable proportion in different wines, the strength of the preparation, when thus made, must necessarily vary. The preparation, as made by the old London formula, is also variable and at the same time deficient in strength. Wine is not capable of taking up sufficient of the double salt to form a preparation of adequate strength. A good wine of iron may be formed by dissolving an ounce of the salt in 12 fluidounces of water, mixed with 12 fluidounces of sherry wine. When thus formed, each fluidounce will contain a scruple of the double tartrate. The dose of a wine of this strength is one or two tablepoonfuls two or three times a day.

Dr. Ure has proposed the *tartrate of protoxide of iron* for medical use. He makes it by acting on clean iron filings, or bits of iron wire, with a solution of tartaric acid. The iron is protoxidized at the expense of the water, and uniting with the tartaric acid produces the tartrate in the form of a powdery matter, which is obtained separate by diffusing it through the liquid, decanting, and washing on a filter. The salt formed is nearly white, pulverulent, insoluble in water, and possesses a mild chalybeate taste.

Properties. Tartrate of iron and potassa, as obtained by the U. S. formula, has a dark-brown colour. When held, in thin pieces, between the eye and the light it is ruby-red. It is wholly soluble in about four parts of water at 60°, and the solution has a dark brown colour. Its taste is feebly chalybeate. Prepared according to the London formula, it is deliquescent and has a dark olive-green colour. When kept for several months, the London preparation assumes, according to Mr. Procter, a mottled, light green colour, is much less soluble than when first made, and exhales an ammoniacal odour. When pure, tartrate of iron and potassa is perfectly neutral to test paper, and at common temperatures does not yield a precipitate with potassa, soda, or ammonia. Ferrocyanuret of potassium does not render it blue, unless an acid be added. The non-action of this test shows that the iron is in a peculiar state of combination. It is incompatible with astringent vegetable infusions which give rise to a dark-coloured precipitate. When prepared by using the bitartrate and iron filings, it is apt to contain metallic iron, detected by the magnet, and a large proportion of it is usually insoluble in water.

Composition. When prepared according to the U. S. formula, it has the composition assigned to it by Soubeiran and Capitaine; namely, one eq. of tartrate of sesquioxide of iron, and one of tartrate of potassa. When it has this composition it contains 30 per cent. of sesquioxide of iron. According to Phillips, the preparation made according to the London formula consists of one eq. of bitartrate of sesquioxide of iron, and two of tartrate of potassa, and contains only 18 per cent. of sesquioxide. The Edinburgh preparation corresponds with the London.

Medical Properties. Tartrate of iron and potassa is an agreeable chalybeate, and, when made according to the U. S. formula, may be depended upon for activity and uniformity of composition. From its slight taste and ready solubility, it forms one of the best ferruginous preparations for ex-

hibition to children. The dose for an adult is from ten grains to half a drachm, given in solution, or combined with an aromatic or bitter in the form of bolus. B.

FERRI FERROCYANURETUM. U. S. FERRI PERCYANIDUM. Lond. FERRI CYANURETUM. Dub. *Ferrocyanuret of Iron. Pure Prussian Blue.*

“Take of Sulphate of Iron *four ounces*; Sulphuric Acid *three fluidrachms and a half*; Nitric Acid *six fluidrachms* or a sufficient quantity; Ferrocyanuret of Potassium *four ounces and a half*; Water *two pints*. Dissolve the Sulphate of Iron in a pint of the Water, and having added the Sulphuric Acid, boil the solution. Pour into it the Nitric Acid, in small portions, boiling the liquid for a minute or two after each addition, until it no longer produces a dark colour; then allow the liquid to cool. Dissolve the Ferrocyanuret of Potassium in the remainder of the Water, and add this solution gradually to the first liquid, agitating the mixture after each addition; then pour it upon a filter. Wash the precipitate with boiling water until the washings pass tasteless. Lastly, dry it and rub it into powder.” U. S.

Prussian blue has heretofore been officinal in the U. S. Pharmacopœia in the impure commercial form; but upon the last revision of the work, it was thought advisable to introduce it in a pure state, and hence the above formula was devised for its preparation. It is officinal also in the London and Dublin Pharmacopœias, in which works it is placed in the list of the Materia Medica. In the Dublin Pharmacopœia, the commercial Prussian blue is recognised; in the London, the pure substance is, no doubt, intended, as tests are given for ascertaining its purity.

In the process above given, the sulphate of protoxide of iron in solution is first acidulated with sulphuric acid, and then converted into the tersulphate of the sesquioxide by means of nitric acid. The object of the addition of the sulphuric acid, is to provide for the higher saturating power of the sesquioxide over the protoxide, and thus to prevent the precipitation of the subsulphate of the sesquioxide. The tersulphate is then decomposed by the gradual addition of a solution of ferrocyanuret of potassium. Three eqs. of ferrocyanuret, and two of tersulphate of sesquioxide of iron, are mutually decomposed, with the result of forming one eq. of Prussian blue, or the 3-4 ferrocyanuret of iron which precipitates, and six eqs. of sulphate of potassa which remain in solution. Ferrocyanogen is a tercyanuret of iron (FeCy_3); and, representing it by its symbol Cfy, we may compactly express the above reactions by the following equation: $3\text{CfyK}_2 + 2(\text{Fe}_2\text{O}_3, 3\text{SO}_3) = (3\text{Cfy} + 4\text{Fe}) + 6(\text{KO}, \text{SO}_3)$. Prussian blue contains the elements of six eqs. of water, which cannot be separated without the destruction of the compound. Adding these elements, we may suppose it to become a hydroferrocyanate of the sesquioxide of iron, represented by the formula, $3\text{CfyH}_2 + \text{Fe}_4\text{O}_6$. From the formula given for the anhydrous compound ($3\text{Cfy} + 4\text{Fe}$), it is evident that it contains nine eqs. of cyanogen, and seven of iron.

Preparation for Use in the Arts. Prussian blue is manufactured on the large scale as follows: A mixture made of equal parts of carbonate of potassa (pearlash of commerce), and animal matter, such as dried blood, hair, the shavings of horn, &c., is calcined at a red heat in an iron vessel, until it becomes pasty. The mass, when cold, is thrown, by portions at a time, into twelve or fifteen times its weight of water, with which it is stirred for half an hour. The whole is then put upon a linen filter; and the clear

solution obtained is precipitated by a mixed solution of two parts of alum and one of the sulphate of protoxide of iron. An effervescence occurs, due principally to carbonic acid; and a very abundant precipitate is thrown down, of a blackish-brown colour. This precipitate is washed by decantation, by means of a large quantity of water, which is renewed every twelve hours. By these washings, which last from twenty to twenty-five days, the precipitate becomes, successively, greenish-brown, bluish, and finally deep-blue. When of the latter colour, it is collected and allowed to drain upon a cloth, after which it is divided into cubical masses, dried, and thrown into commerce.

Properties. Pure Prussian blue is a tasteless powder, insoluble in water and alcohol, and having a rich deep blue colour. It is insoluble in dilute acids, decomposed by fuming nitric acid, and dissolved without decomposition by strong sulphuric acid, forming a white mass of the consistence of paste, from which the Prussian blue may be precipitated unchanged by water. Concentrated muriatic acid decomposes it, dissolving sesquioxide of iron, and liberating hydroferrocyanic acid. Boiled with red oxide of mercury it generates bityanuret of mercury. (See *Hydrargyri Cyanuretum*.) By the contact of a red-hot body it takes fire and burns slowly, leaving a residue of sesquioxide of iron. When it is heated in close vessels, water, hydrocyanic acid, and carbonate of ammonia are evolved, and carburet of iron is left. Its composition has been given above. The Prussian blue of commerce was discovered by accident in 1710, by Diesbach, a preparer of colours at Berlin. It has the same general properties as the pure substance. It occurs in small rectangular masses, which are heavier than water, and have a fracture presenting a bronzed appearance. Besides the constituents of pure Prussian blue, it always contains alumina, derived from the alum employed in its manufacture, and which serves to give it a body as a pigment, and uncombined sesquioxide of iron. These substances may be detected by boiling the pigment with diluted muriatic acid, and precipitating the filtered solution with ammonia. Pure Prussian blue, treated in a similar manner, yields no precipitate, and may thus be discriminated from the commercial substance.

Medical Properties, &c. Prussian blue is supposed to act as a tonic, febrifuge, and alterative. Dr. Zollickoffer, of Maryland, has recommended it as a remedy in intermittent and remittent fevers, and deems it to be particularly adapted to such cases occurring in children, on account of the smallness of the dose and its want of taste. He considers it more certain, prompt, and efficacious than the bark; while it has the advantage of being admissible in the state of pyrexia, and of not disagreeing with the most irritable stomach. It has also been used by Dr. Kirchoff, of Ghent, in epilepsy with good success. Dr. Bridges, of this city, exhibited it in a case of severe and protracted facial neuralgia, with considerable relief, after the more usual remedies in this complaint had been tried with little or no benefit. It is sometimes employed as an application to ill-conditioned ulcers, mixed with some simple ointment, in the proportion of a drachm to the ounce. The dose of pure Prussian blue for an adult is from three to five grains, repeated several times a day, and gradually increased until some obvious effect is produced.

Off. Prep. Hydrargyri Cyanuretum, *U. S., Dub., Lond.* B.

FERRI IODIDUM. *U. S., Lond., Ed.* Iodide of Iron.

“Take of Iodine two ounces; Iron Filings an ounce; Distilled Water a pint and a half. Mix the Iodine with a pint of the Distilled Water, in a

porcelain or glass vessel, and gradually add the Iron Filings, stirring constantly. Heat the mixture gently until the liquid acquires a light greenish colour; then filter, and after the liquid has passed, pour upon the filter half a pint of the Distilled Water boiling hot. When this shall have passed, evaporate the filtered liquor, at a temperature not exceeding 212° , in an iron vessel, to dryness. Keep the dry Iodide in a closely-stopped bottle." *U. S.*

The *London* process is the same as that of the *U. S. Pharmacopœia*, except that the College directs only two-thirds of the quantity of iron filings, and orders that the preparation should be kept from the light.

"Take any convenient quantity of Iodine, Iron Wire, and Distilled Water, in the proportions for making Solution [Syrup] of Iodide of Iron. Proceed as directed for that process; but before filtering the solution, concentrate it to one-sixth of its volume, without removing the excess of Iron Wire. Put the filtered liquor quickly in an evaporating basin, along with twelve times its weight of quicklime around the basin, in some convenient apparatus, in which it may be shut up accurately in a small space, not communicating with the general atmosphere. Heat the whole apparatus in a hot air-press, or otherwise, until the water be entirely evaporated; and preserve the dry iodide in small well-closed bottles." *Ed.*

In this process iron is made to unite with iodine by the intervention of water. The mixture at first is orange-coloured, from the circumstance that all the iodine has not united with the iron; but after the application of heat it becomes fully saturated and limpid, and assumes a greenish colour. It is now a solution of iodide of iron, and yields the solid salt by evaporation. The proportion of the iron, taken in the *U. S.* and *Edinburgh Pharmacopœias*, is the same, namely, half the weight of the iodine; in the *London*, it is one-third of the weight of the latter. The *London* proportion gives an excess of iron; but as it is useful to keep the iodide constantly in contact with a considerable quantity of metallic iron, the greater excess of metal ordered in the *U. S.* and *Edinburgh Pharmacopœias* has its advantages, and is not objectionable on the score of expense. Fine iron wire, recently cleaned, is directed by the *Edinburgh College* on account of its purity; but iron filings dissolve more readily, and, if carefully selected, will be sufficiently pure. It is exceedingly difficult to obtain the solid salt perfectly pure, so great is the proneness of the solution to absorb oxygen, whereby the iodide becomes, in part, converted into sesquioxide. This change is prevented to a certain extent in the *U. S.* and *London Pharmacopœias*, by evaporating to dryness in an *iron* vessel; and by the *Edinburgh College*, by concentrating the solution, before filtering, in contact with the excess of iron wire, and afterwards evaporating it in a hot air-press, subjected to the drying influence of quicklime.

Properties. Iodide of iron is a crystalline substance, exceedingly deliquescent, of a greenish-black colour, and styptic, chalybeate taste. "When carefully prepared by the *Edinburgh* formula, it has a dark grayish-black metallic appearance, and irregularly foliated texture, not unlike iodine itself." (*Christison's Dispensatory.*) Its solution, by evaporation with as little contact of air as possible, affords transparent, green, tabular crystals. When heated moderately it fuses, and, on cooling, becomes an opaque crystalline mass, having an iron-gray colour and metallic lustre. At a higher temperature it emits violet-coloured vapours, and the iron is left in the state of sesquioxide. It is very soluble both in water and alcohol. When recently prepared it is wholly soluble in water, forming a pale green solution; but if made for some time, it almost unavoidably contains some sesquioxide of iron, from a

partial decomposition, and will not be entirely soluble. The aqueous solution is very liable to spontaneous decomposition from the absorption of oxygen, becoming orange-red from the generation of sesquioxide, and depositing sesquioxide of iron. During this change, two eqs. of protiodide of iron are decomposed. The two eqs. of iron unite with three eqs. of the oxygen of the air, to form one eq. of sesquioxide, and the corresponding two eqs. of iodine convert four eqs. of protiodide into two eqs. of sesquioxide. The reaction is best explained by the following equation: $6\text{FeI} + 3\text{O} = 2\text{Fe}_2\text{I}_3 + \text{Fe}_2\text{O}_3$. The whole solution becomes finally converted into one of sesquioxide of iron. The above is the explanation usually given of the result of this spontaneous decomposition; but, as the partially decomposed solution strikes a blue colour with starch, a more probable one is, that the excess of iodine exists in it as free iodine, and not as a constituent of a newly generated sesquioxide. The solution of protiodide may be partially protected from change by placing a coil of iron wire in the bottle containing it; for so soon as any iron is sesquioxidized and deposited, the liberated iodine is converted back again into protiodide by a portion of the protecting metal. Here it is perceived that the formation of sesquioxide of iron is not prevented. The protection of the solution may be accomplished perfectly and without deposition of sesquioxide, by means of saccharine matter. (See *Liquor Ferri Iodidi*.) Iodide of iron is incompatible with alkalies and their carbonates, with lime-water, and with all other substances by which sulphate of iron is decomposed. When crystallized it consists of one eq. of iodine 126.3, one of iron 28, and five of water 45 = 199.3.

Medical Properties and Uses. Iodide of iron was first employed in medicine by Dr. Pierquin in 1824. (*Mémorial Pharmaceutique*.) It was first used in the United States in 1832 by Dr. Samuel Jackson, of this city, at whose request it was prepared in solution by Mr. E. Durand. (*Journ. of the Phil. Col. of Pharm.* iv. 287. Jan. 1833.) Dr. A. T. Thomson, of London, presented it to the notice of the profession in England, as a remedy, in 1834. (*Obs. on the Ioduret and Hydriodate of Iron*.) Its powers are those of a tonic, alterative, diuretic, and emmenagogue. As a therapeutic agent it acts more like the preparations of iron than those of iodine. It sometimes sharpens the appetite and promotes digestion, and occasionally acts as a laxative and diuretic. After having been continued for several days, its constituents may be detected in the urine. When it does not act on the bowels, it generally augments the urine. Its use blackens the stools and lessens their fetor. It is chiefly employed in scrofulous complaints, swellings of the cervical glands, visceral obstructions attended with deficient action, chlorosis, atonic amenorrhœa, and leucorrhœa. In the two diseases last mentioned, Dr. Pierquin employed it with success. In old and obstinate syphilitic ulcers, M. Baumes, of Lyons, used it with satisfactory results. He gave it in the form of pill, conjoined with extract of opium, and sometimes increased the dose to 20 grains in the course of twenty-four hours. When given in pill, however, the iodide is necessarily much changed, and contains more or less free iodine. In secondary syphilis, occurring in debilitated and scrofulous subjects, Ricord has found it a valuable remedy. The dose is three grains, gradually increased to eight or more. It should never be given in the form of pill, on account of its proneness to decomposition; but always in aqueous solution, protected by saccharine matter. (See *Liquor Ferri Iodidi*.) For forming enemata, injections for the vagina, and lotions for ulcers, one or two drachms of the salt may be dissolved in a pint of water. In view of the serious objections which apply to the solid iodide

of iron, it might well be dispensed with in the Pharmacopœias. Solutions for external use might be formed by reducing the saccharine solution with water to any desired extent, at the moment of using them; and, in cases in which it might be desirable to give the salt in the solid state, the same preparation could be reduced to a saccharine mass proper for making pills by evaporation to dryness. B.

LIQUOR FERRI IODIDI. U. S. FERRI IODIDI SYRUPUS. Ed.
Solution of Iodide of Iron. Syrup of Iodide of Iron.

“Take of Iodine *two ounces*; Iron Filings *an ounce*; Prepared Honey *five fluidounces*; Distilled Water *a sufficient quantity*. Mix the Iodine with ten fluidounces of the Distilled Water, in a porcelain or glass vessel, and gradually add the Iron Filings, stirring constantly. Heat the mixture gently until the liquor acquires a light-greenish colour; then, having added the Honey, continue the heat a short time, and filter. Lastly, pour the Distilled Water upon the filter, and allow it to pass until the whole of the filtered liquor measures twenty fluidounces. Keep the solution in closely-stopped bottles.” U. S.

“Take of Iodine (dry) *two hundred grains*; fine Iron Wire, recently cleaned, *one hundred grains*; White Sugar, in powder, *four ounces and a half*; Distilled Water, *six fluidounces* [Imperial measure]. Boil the Iodine, Iron, and Water together in a glass matrass, at first gently to avoid the expulsion of Iodine vapour, afterwards briskly, until about two fluidounces of liquid remain. Filter this quickly, while hot, into a matrass containing the Sugar; dissolve the Sugar with a gentle heat, and add Distilled Water, if necessary, to make up six fluidounces. Twelve minims contain one grain of Iodide of Iron.” Ed.

These preparations are intended to furnish a solution of iodide of iron, protected from change by saccharine matter. The saccharine matter selected in the U. S. formula is honey; in the Edinburgh, sugar. Both formulas direct a determinate quantity of the preparation to be made; but the U. S. solution contains about 58 grains of the dry iodide of iron to the fluidounce; while the Edinburgh syrup contains, in the same measure, only 40 grains. The Edinburgh preparation is strictly a syrup as it is called, on account of the large quantity of sugar it contains; whereas the honey is diluted to a very considerable extent in the U. S. formula. The mode of making the iodide of iron in both the formulas is precisely the same as that given under the head of *Ferri Iodidum*. The Edinburgh College filters, while hot, into the vessel containing the sugar; so that, for a short interval of time, the solution is not under the protecting influence of either the iron or sugar. In the U. S. formula, the better plan is pursued of adding the saccharine matter before filtration, and while the solution is still in contact with the excess of iron. The Edinburgh College directs the iodine to be dry; because, if moist, as the British iodine often is, less iodide of iron will be formed, and the syrup will be proportionably weaker. (See page 392 for the method of drying iodine.) In the U. S. formula, the iodine is assumed to be pure, and, therefore, dry.

The plan of protecting the solution of iodide of iron from change by saccharine matter originated with M. Frederking, of Riga, who published a formula for the purpose in *Buckner's Repertorium* in 1839. (See *Amer. Journ. of the Med. Sci. for Feb. 1840*.) The same plan was proposed in a paper by Mr. Wm. Procter, Jr., contained in the *Amer. Journ. of Pharmacy* for April, 1840. In this paper, Mr. Procter detailed his experiments with different saccharine substances in order to determine their relative

protecting power, pronounced in favour of prepared honey for that purpose, and gave a formula for a permanent solution of the iodide, which is the basis of that adopted in the U. S. Pharmacopœia. In the *Journal de Pharmacie* for March 1841, Dr. Dupasquier, of Lyons, claims to have made a pure iodide of iron, protected by the syrup of gum, as early as 1838. In the *Pharmaceutical Transactions* for August 1841, Dr. A. T. Thomson gave a paper in which he confirmed the results of Frederking and Procter, and proposed a formula for a *strong syrup*, which is the basis of that adopted in the Edinburgh Pharmacopœia.

Properties. The U. S. *solution of iodide of iron* is a transparent liquid, free or nearly so from sediment, and of a pale greenish colour. On the addition of sulphuric acid, it becomes brown, and emits violet vapours if heated. It should not contain any free iodine, which, if present, may be detected by the production of a blue colour with starch. The Edinburgh *syrup* is a transparent liquid, either colourless or pale yellowish-green, and without sediment, even when exposed to the air. When concentrated it becomes brown, and, if evaporated to dryness, it forms a mass which may be called the saccharine iodide, and which is not entirely soluble again, a little sesquioxide being left. This saccharine iodide, being protected by the sugar it contains, is not liable to the same objections as the pure solid salt, and may be conveniently made into pills.

Medical Properties. These have been detailed under the head of *Ferri Iodidum*. The dose of the *solution* is from 30 to 75 drops, sufficiently diluted with water; that of the Edinburgh *syrup*, one-half larger. The dilution should be made by the patient at the moment it is taken, and in order to guard against injury to the teeth, the mouth should be carefully washed after each dose.

B.

FERRI OXIDUM HYDRATUM. U. S. FERRUGO. *Ed. Hydrated Oxide of Iron. Hydrated Sesquioxide of Iron.*

“Take of Sulphate of Iron *four ounces*; Sulphuric Acid *three fluidrachms and a half*; Nitric Acid *six fluidrachms or a sufficient quantity*; Solution of Ammonia *a sufficient quantity*; Water *two pints*. Dissolve the Sulphate of Iron in the Water, and having added the Sulphuric Acid, boil the solution; then add the Nitric Acid in small portions, boiling the liquid for a minute or two after each addition, until the Acid ceases to produce a dark colour. Filter the liquid, allow it to cool, and add Solution of Ammonia in excess, stirring the mixture briskly. Wash the precipitate with water until the washings cease to yield a precipitate with chloride of barium, and keep it in close bottles with water sufficient to cover it.”

U. S.

“Take of Sulphate of Iron *four ounces*; Sulphuric Acid (commercial) *three fluidrachms and a half*; Nitric Acid (D. 1.380) *nine fluidrachms*; Stronger Aqua Ammoniæ *three fluidounces and a half*; Water *two pints* [Imperial measure]. Dissolve the Sulphate in the Water, add the Sulphuric Acid, and boil the solution; add then the Nitric Acid in small portions, boiling the liquid for a minute or two after each addition, until it acquires a yellowish-brown colour, and yields a precipitate of the same colour with ammonia. Filter, allow the liquid to cool, and add in a full stream the Aqua Ammoniæ, stirring the mixture briskly. Collect the precipitate on a calico filter; wash it with water till the washings cease to precipitate with nitrate of baryta; squeeze out the water as much as possible, and dry the precipitate at a temperature not exceeding 180°. When this preparation is kept as an antidote for poisoning with arsenic, it is preferable to preserve it in the moist state, after being simply squeezed.”

This is a new officinal of the U. S. and Edinburgh Pharmacopœias, introduced on account of its importance as an antidote to the poison of arsenious acid. The first step of the process is to convert the sulphate of protoxide of iron into the tersulphate of the sesquioxide, precisely as is done in the U. S. formula for pure Prussian blue. The sesquioxide is then thrown down in the hydrated state by the addition of ammonia in excess, and the precipitate is washed with water to remove adhering sulphate of ammonia, until the washings cease to precipitate with a barytic salt. In the U. S. Pharmacopœia the precipitate is directed to be kept in close bottles with sufficient water to cover it, in which state it is most convenient for use as an antidote. The Edinburgh College directs it to be kept in two states,—dried at a temperature not exceeding 180° for use as a medicine, and in the moist state as an antidote.

Properties. Hydrated oxide of iron, as directed to be kept by the U. S. formula, is a soft, moist, reddish-brown magma. If dried at a heat not exceeding 180° , and afterwards pulverized, it forms a reddish-brown powder, not attracted by the magnet, being the sesquioxide in the state of hydrate, containing about 18 per cent. of water. In this state it is wholly and readily soluble in muriatic acid without effervescence. If exposed to a red heat it loses the combined water, and becomes the anhydrous sesquioxide, less easily soluble in acids, improper for medicinal use, and altogether without effect as an antidote. Hydrated oxide of iron consists of one eq. of sesquioxide 80, and two of water $18=98$, and is represented by the formula $\text{Fe}_2\text{O}_3+2\text{HO}$.

Medical Properties and Uses. The hydrated oxide, being readily soluble in acids, would no doubt form, in the dry state, a good ferruginous preparation for medicinal employment. Its antidotal powers in cases of poisoning by arsenic, the manner in which it acts, and the mode of using it, are fully explained under the head of arsenious acid, page 23. Its power of rendering arsenious acid insoluble is readily shown by agitating a solution of the acid with a considerable excess of the moist oxide, filtering, and then testing the filtered solution for arsenious acid; when not a trace of the metal can be detected, even by sulphuretted hydrogen. The hydrated oxide, as obtained by the formulæ above given, contains a little ammonia, which is thought by some to assist its antidotal powers. At least it has been ascertained that the sesquioxide, precipitated by potassa, is a less efficient antidote to arsenic than the officinal preparation, and must be used in quantities three or four times as large to produce the same effect. The dry hydrate, rubbed up with water, is in the same proportion weaker than the pulpy hydrate. It has already been mentioned, under the head of arsenious acid, that the officinal subcarbonate of iron (precipitated carbonate) possesses antidotal powers to arsenic, though in an inferior degree; but this statement will not apply to it, if it has been exposed to a red heat, as is improperly done by some manufacturing chemists. By ignition in this way it becomes anhydrous, and is rendered altogether inefficient as an antidote.

B.

FERRI OXIDUM NIGRUM. *Ed.* FERRI OXYDUM NIGRUM. *Dub.* *Black Oxide of Iron. Martial Ethiops.*

“Take of Sulphate of Iron *six ounces*; Sulphuric Acid (commercial) *two fluidrachms and two fluidscruples*; Pure Nitric Acid *four fluidrachms and a half*; Stronger Aqua Ammonia *four fluidounces and a half*; Boiling Water *three pints* [Imperial measure]. Dissolve half the Sulphate in half the boiling Water, and add the Sulphuric Acid; boil; add the Nitric Acid

by degrees, boiling the liquid after each addition briskly for a few minutes. Dissolve the rest of the Sulphate in the rest of the boiling Water; mix thoroughly the two solutions; and immediately add the Ammonia in a full stream, stirring the mixture at the same time briskly. Collect the black powder on a calico-filter; wash it with water till the water is scarcely precipitated by solution of nitrate of baryta, and dry it at a temperature not exceeding 180°." *Ed.*

"Wash the Scales of the Oxide of Iron, found at the blacksmith's anvil, with water; and having dried them, separate them from impurities by means of a magnet. Then reduce them to powder, of which the finest particles are to be collected in the manner directed for the preparation of chalk." *Dub.*

The preparations called black oxide of iron in the Edinburgh and Dublin Pharmacopœias are not precisely identical. The oxide of the Edinburgh College is made by a new process, that recommended by Wöhler, which consists in precipitating by ammonia, a solution of the mixed sulphates of protoxide and sesquioxide of iron. Half the sulphate of iron taken in the formula, after being dissolved in water, is acidulated with sulphuric acid, and converted into the tersulphate of the sesquioxide by means of nitric acid. The object of the addition of the sulphuric acid is explained under the head of Prussian blue. (See *Ferri Ferrocyanauretum*.) The other half of the sulphate is dissolved in water, and the two solutions, being thoroughly mixed, form a compound solution of sulphate of the protoxide and sulphate of the sesquioxide of iron. From this the ammonia throws down, at the same moment, both the protoxide and sesquioxide, which unite chemically to form the black oxide of the Edinburgh College.

The black oxide of the Dublin College is obtained from the scales of the oxide of iron. The nature and composition of these scales have been explained under the head of *Ferrum Oxydi Squamæ*. By washing, they are freed from accidental impurities; and as they are not at the maximum of oxidation, they are capable of further purification by the use of the magnet, after which they are reduced to an impalpable powder. This preparation, besides occasionally containing metallic iron, varies in composition even as an oxide, as explained at page 330. It is, therefore, not so eligible a preparation as that obtained by the new process of the Edinburgh Pharmacopœia. The black oxide of the French Codex is nearly equivalent in composition to the Edinburgh oxide, and is obtained as follows. Take of fine and pure iron filings any quantity. Place them in a stoneware dish, and add sufficient water to wet them perfectly and uniformly. Heap up the mixture, and abandon it to the action of the air. After it has become warm, stir it with a spatula, and add water to make up for that which may evaporate, so as to keep the mixture constantly moist. At the end of two or three days the oxidation will have terminated, when the product is to be put in a mortar, and strongly triturated, in order to separate the oxide from the iron. Throw the whole upon a fine hair sieve, and wash with abundance of water, until the washings no longer pass of a black colour. The water thus obtained contains the oxide, and must be decanted with rapidity, after agitation. The oxide, after having subsided from the decanted water, is put upon a linen cloth, drained and pressed. It is then put between the folds of bibulous paper, and rapidly dried, in order, as far as possible, to avoid oxidation.

Properties. The Edinburgh oxide is a dark grayish-black powder, unchangeable in the air and slowly attracted by the magnet. When dried in mass and then broken, it presents a shining fracture. It is wholly solu-

ble in muriatic acid without effervescence, and may be thrown down again, as a black precipitate, by ammonia. When heated in close vessels it suffers no change except the loss of water; in open vessels it absorbs oxygen and is converted entirely into sesquioxide. It consists of two eqs. of protoxide of iron, one of sesquioxide, and two of water, and its formula is $2\text{FeO} + \text{Fe}_2\text{O}_3 + 2\text{HO}$. It is, therefore, not identical with the native black oxide, the *ferroso-ferric oxide* of Berzelius, which consists of single equivalents of the two oxides. It is perceived by the symbols given, that the two oxides are united in such proportions as to contain the same quantity of iron; and this composition corresponds with what it should be, according to the direction given in the formula to divide the sulphate of iron into two equal portions, each of which necessarily contains the same quantity of metallic iron.

Medical Properties. The black oxide from the scales of iron has been long used as a chalybeate, and is highly esteemed. The dose is from five to twenty grains, two or three times a day. The black oxide of the Edinburgh College has not been tried as a medicine, so far as we know; but it may be considered superior as a pharmaceutical preparation to the ordinary black oxide, on account of its uniform composition, and permanency under the influence of air and moisture. B.

FERRI OXYDUM RUBRUM. *Dub. Red Oxide of Iron.*

“Expose Sulphate of Iron to heat, until the water of crystallization is expelled. Then roast it by an intense fire as long as acid vapours arise. Wash the red oxide until the washings, when examined by litmus, appear free from acid. Lastly, dry it on bibulous paper.” *Dub.*

When sulphate of iron, or *green vitriol*, is heated, it swells up, and undergoes the aqueous fusion, and afterwards, by losing its water of crystallization, becomes a dry grayish-white mass, consisting of anhydrous sulphate of iron. This, by the application of a strong heat, is decomposed; the iron becomes sesquioxidized at the expense of part of the acid, and sulphurous and sulphuric acids are given off. The sesquioxide, however, is not perfectly pure, but still contains a small portion of acid, to remove which it requires to be washed.

Properties, &c. Red oxide of iron is a reddish-brown, tasteless, insoluble powder, called *colcothar* in commerce. It should not be deliquescent, and should dissolve in muriatic acid without effervescence. If it contain copper, its muriatic solution will deposit this metal on a bright piece of iron. It consists of two eqs. of iron 56, and three of oxygen $24 = 80$. It is, therefore, a *sesquioxide of iron*. As it is anhydrous, it has no effect as an antidote to arsenious acid. (Orfila, *Amer. Journ. of Pharm.* xiii. 331.) This is a useless preparation, and was properly dismissed from the U.S. and Edinburgh Pharmacopœias upon their last revision.

Off. Prep. Emplastrum Ferri, *Dub.*

B.

FERRI PHOSPHAS. *U.S. Phosphate of Iron.*

“Take of Sulphate of Iron *five ounces*; Phosphate of Soda *six ounces*; Water *a gallon*. Dissolve the Sulphate of Iron and Phosphate of Soda severally in four pints of the Water; then mix the solutions, and set the mixture by that the powder may subside; lastly, having poured off the supernatant liquor, wash the Phosphate of Iron with hot water, and dry it with a gentle heat.” *U.S.*

This preparation is the result of a double decomposition between the saline materials employed. The sulphuric acid combines with the soda and remains in solution as sulphate of soda; while the phosphoric acid,

uniting with the protoxide of iron, falls as phosphate of iron. The amount of water directed is useful to insure a prompt and complete mutual reaction of the two salts. If the ferruginous sulphate be a perfect sulphate of the protoxide, the precipitate, as first thrown down, will be white; but it quickly absorbs oxygen and becomes bluish-white. It is in the form of an insoluble powder of a bright slate colour. According to Berzelius, it is a mixture of the phosphates of the two oxides of iron.

Medical Properties and Uses. Phosphate of iron possesses the general properties of the ferruginous preparations, and has been given with advantage in amenorrhœa and some forms of dyspepsia. It was introduced into the U. S. Pharmacopœia at the suggestion of Dr. Hewson of this city, who found it, after an extensive experience, to be a valuable chalybeate. The dose is from five to ten grains.

B.

FERRI RUBIGO. *Dub.* *Rust of Iron.*

“Take of Iron Wire, *any quantity.* Cut it into pieces and expose it to the air, moistened with water, until it is converted into rust. Rub this in an iron mortar; then separate the finest powder by the affusion of water, and dry it.” *Dub.*

Rust of iron is reduced to an impalpable powder by levigation and elutriation, and then made up into small conical masses like prepared chalk. According to Berzelius, it is a hydrated sesquioxide of iron, containing frequently a little carbonate of protoxide. It is formed in consequence of the decomposition of the water, the oxygen of which converts the iron chiefly into sesquioxide, but partly also into protoxide, which absorbs carbonic acid from the atmosphere. Iron, in the form of wire, on account of its greater purity, is preferable to the filings for forming this preparation.

Properties, &c. Rust of iron is in the form of a red powder of a slightly styptic taste. Its medical properties and dose are the same as those of the subcarbonate; but being less soluble in acids it is a less eligible preparation. It may be considered as a superfluous article, and has been very properly expunged from the official lists of the U. S. and Edinburgh Pharmacopœias.

FERRI SUBCARBONAS. *U. S.* FERRI SESQUIOXYDUM. *Lond.* FERRI OXIDUM RUBRUM. *Ed.* FERRI CARBONAS. *Dub.* *Subcarbonate of Iron. Sesquioxide of Iron. Precipitated Carbonate of Iron.*

“Take of Sulphate of Iron *eight ounces*; Carbonate of Soda *nine ounces*; Boiling Water *a gallon.* Dissolve the Sulphate of Iron and Carbonate of Soda severally in four pints of the Water; then mix the solutions, and having stirred the mixture, set it by that the powder may subside; lastly, having poured off the supernatant liquor, wash the Subcarbonate of Iron with hot water, wrap it in bibulous paper, and dry it with a gentle heat.” *U. S.*

“Take of Sulphate of Iron *four pounds*; Carbonate of Soda *four pounds and two ounces*; Boiling Water *six gallons* [Imperial measure]. Dissolve the Sulphate of Iron and Carbonate of Soda, separately, in three gallons of Water. Then mix the solutions together, and set them by that the powder may subside. Lastly, the supernatant liquor being poured off, wash the precipitate with water, and dry it.” *Lond.*

“Take of Sulphate of Iron *four ounces*; Carbonate of Soda *five ounces*; Boiling Water *half a pint* [Imperial measure]; cold Water *three pints and a half* [Imp. meas.]. Dissolve the Sulphate in the boiling Water, add the cold Water, and then the Carbonate of Soda, previously dissolved in about

thrice its weight of water. Collect the precipitate on a calico filter; wash it with water till the water is but little affected with solution of nitrate of baryta, and dry it in the hot air-press, or over the vapour-bath." *Ed.*

"Take of Sulphate of Iron *twenty-five parts*; Carbonate of Soda *twenty-six parts*; Water *eight hundred parts*. Dissolve the Sulphate of Iron in the Water, then add the Carbonate of Soda, previously dissolved in a sufficient quantity of water, and completely mix. Wash the Carbonate of Iron which is thrown down with warm water, and then dry it." *Dub.*

When the solutions of carbonate of soda and sulphate of iron are mixed together, a hydrated carbonate of protoxide of iron, of a pale bluish colour, is thrown down, and sulphate of soda remains in solution. The equivalent quantities of the *crystallized* salts for mutual decomposition are 130.1 of the sulphate and 143.42 of the carbonate. Taking the quantity of sulphate of iron at 8 parts, the London and Dublin Pharmacopœias order of carbonate of soda 8.3 parts; the U. S. Pharmacopœia 9 parts, and the Edinburgh 10 parts. The proportions of the London and Dublin Colleges coincide most nearly with the equivalents. The precipitate, during the washing and drying, absorbs oxygen, and loses nearly the whole of its carbonic acid, whereby it becomes converted almost entirely into sesquioxide of iron. This being its chemical nature, the London College, in their last Pharmacopœia, have given it the new name of sesquioxide of iron; but as this name is applicable to the rust of iron, the red oxide obtained by calcination from the sulphate, and even to the hydrated oxide used as an antidote to arsenic, the appellation adopted in the U. S. Pharmacopœia of subcarbonate of iron, in allusion to the small quantity of carbonic acid present in it, is more distinctive. Carbonate of potassa will answer to decompose the ferruginous sulphate; but carbonate of soda is preferred, because it produces, in the double decomposition, the sulphate of soda, which, from its greater solubility, is more readily washed away than the sulphate of potassa.

Properties. Subcarbonate of iron is a reddish-brown powder, of a disagreeable, slightly styptic taste; insoluble in water, but dissolving readily in muriatic acid with very slight effervescence of carbonic acid. After precipitation by ammonia, which throws down the sesquioxide of iron, the supernatant liquor should give no indications of containing any other metal in solution. It is incompatible with acids and acidulous salts. In composition it is a hydrated sesquioxide of iron, containing a little protoxide and carbonic acid.

Medical Properties and Uses. Subcarbonate of iron is tonic, alterative, and emmenagogue, and is employed for all the purposes to which the preparations of iron are generally applicable. It was recommended by Mr. Carmichael in cancer, and is said sometimes to prove useful. Mr. Hutchinson brought it into notice as a remedy for neuralgia; and an extensive experience with it in that disease has established its value. It is also useful in chorea, in chlorosis, and, generally, in those diseases in which the blood is deficient in colouring matter. It has been used by Dr. Woollam, Dr. Shearman, Dr. Elliotson, and others, in traumatic tetanus, with success in twelve cases and failure in three. In the second stage of whooping-cough, Dr. Steymann represents it to be a prompt and efficacious remedy. When prescribed as a tonic, the usual dose is from five to thirty grains three times a day, given in pill or powder, and frequently combined with aromatics and vegetable tonics. In neuralgia, chorea and tetanus, it is administered in doses of from one to two teaspoonfuls. No nicety need be observed in the

dose; its only obvious effect in very large doses being a slight nausea, and a sense of weight at the stomach. Its use gives the stools a black colour.

The subcarbonate of iron acts as an antidote to the poison of arsenious acid, provided it has not been exposed to a red heat, and, though not so powerful as the hydrated oxide in the form of magma, should always be used till the latter can be procured. (See page 24.)

FERRI SULPHAS. *U. S., Lond., Ed., Dub.* Sulphate of Iron. *Green Vitriol.*

"Take of Iron Wire, cut in pieces, *twelve ounces*; Sulphuric Acid *eighteen ounces*; Water *a gallon*. Mix the Sulphuric Acid and Water, and add the Iron; then heat the mixture until effervescence ceases. Pour off the solution, and, having added half a drachm of Sulphuric Acid, filter through paper, allowing the lower end of the funnel to touch the bottom of the receiving vessel. Evaporate the filtered liquor in a matrass until sufficiently concentrated; then set it aside in a covered vessel to crystallize. Drain the crystals in a funnel, dry them on bibulous paper, and keep them in closely stopped bottles." *U. S.*

"Take of Iron Filings *eight ounces*; Sulphuric Acid *fourteen ounces*; Water *four pints* [Imperial measure]. Mix the Sulphuric Acid with the Water, and add the Iron to them. Then apply heat, and when bubbles have ceased to escape, strain the liquor, and set it aside that crystals may form. Evaporate the liquor poured off that it may again yield crystals, and dry them all." *Lond.*

"If the Sulphate of Iron of commerce be not in transparent green crystals, without efflorescence, dissolve it in its own weight of boiling water, acidulated with a little Sulphuric Acid; filter, and set the solution aside to crystallize. Preserve the crystals in well-closed bottles." *Ed.*

"Take of Iron Wire *four parts*; Sulphuric Acid [commercial?] *seven parts*; Water *sixty parts*. Dissolve the metal by the aid of heat, and filter the solution through paper. Lastly, after due evaporation, set the solution aside that crystals may form by slow refrigeration." *Dub.*

The object of the *U. S.*, London and Dublin processes is to make a pure sulphate of the protoxide of iron by direct combination. Sulphuric acid, in a concentrated state, acts but imperfectly on iron; but when diluted, a vigorous action takes place, the oxygen of the water converts the metal into protoxide, with which the sulphuric acid unites, and hydrogen is evolved. The equivalent quantities for mutual reaction are 28 of iron to 49.1 of acid, which is the proportion taken by the London and Dublin Colleges. This proportion is one of iron to one and three-quarters of acid. The *U. S.* proportion is one of iron to one and a half of acid, and gives a quantity of iron one-sixth more than the acid can dissolve. This excess of iron is desirable, as it tends to secure the production of a perfect sulphate of the protoxide. The remaining steps of the *U. S.* process are peculiar, and are intended to secure the formation of a salt entirely free from sesquioxide, by the method of Bonsdorff. This chemist found that when a perfect sulphate of the protoxide of iron was formed in solution by heating dilute sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid be added to the liquid before it is filtered, in order to hold in solution any sesquioxide that may have been formed; at the same time avoiding, as much as possible, the

contact of the air. Hence the directions of the U. S. formula to acidulate with sulphuric acid, to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air, and to cover the vessel containing the concentrated liquid, when it is set aside to crystallize. Iron wire, as being purer, is to be preferred to iron filings in making sulphate of iron. The Edinburgh College gives no formula for making this salt, but directions only for the purification of the commercial sulphate, when this happens to be impure. The salt is dissolved in boiling water, and filtered, which separates the insoluble subsulphate; after which the solution is acidulated with sulphuric acid on the plan of Bonsdorff, and crystallized.

M. Berthemot has proposed a modified plan of procedure, to render sulphate of iron permanent. He first purifies the commercial sulphate in the manner directed by the Edinburgh College, and then adds it, by portions, to boiling distilled water, to which afterwards some iron filings are added. The solution is then quickly filtered, while hot, into a vessel containing alcohol acidulated with sulphuric acid. The pure sulphate of the protoxide immediately precipitates in the form of a bluish-white crystalline powder; while any sesquisalt which may have formed is dissolved by the alcohol, and any free sesquioxide is taken up by the acid. (*Journ. de Pharm.* xxv. 206.)

Sulphate of iron, under the name of *green vitriol* or *copperas*, is manufactured on the large scale, for the purposes of the arts, from the native sulphuret of iron or pyrites by roasting, oxidation through exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and protoxide of iron, which, by their union, form the salt in question. It is made also by our manufacturers of sulphuric acid, by direct combination, from the unconcentrated acid and scraps of old iron.

Properties. Sulphate of iron is in the form of transparent crystals, of a pale bluish-green colour, and having the shape of oblique rhombic prisms. It has a disagreeable styptic taste, and an acid reaction. As prepared by Bonsdorff's method, it is blue verging to green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. When exposed to the air, the crystals absorb oxygen, first become green, and are ultimately covered with a yellow efflorescence of subsulphate of the sesquioxide, insoluble in water. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. Sulphate of iron is soluble in about twice its weight of cold water, and in three-fourths of its weight of boiling water, but is insoluble in alcohol. The aqueous solution is bluish-green; but by standing it attracts oxygen, and is rendered first green and then reddish, depositing, in the mean time, a portion of subsulphate. When heated moderately, it loses six-sevenths of its water of crystallization, and becomes grayish-white. At a red heat it loses its acid, and is converted into the anhydrous sesquioxide of iron, called *colcothar*. (See *Ferri Sulphas Exsiccatus*, and *Ferri Oxydum Rubrum*.) It is incompatible with the alkalis and their carbonates, soaps, lime-water, the chlorides of calcium and barium, the borate and phosphate of soda, nitrate of silver, and the acetate and subacetate of lead. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesquioxide be present, a black compound of the nature of ink. To what extent this change lessens the medicinal activity of the salt, is not well ascertained. Sulphate of iron, as it occurs in the shops, is often impure. The commercial sulphate should never be dispensed by the apothecary until it has un-

dergone a careful purification in the manner directed in the Edinburgh Pharmacopœia. The perfectly pure salt is precipitated white by ferrocyanuret of potassium; but that of ordinary purity gives a blue precipitate, more or less deep, with this test, owing to the presence of some sesquioxide of iron. Copper may be detected by immersing in the solution a bright piece of iron, on which a cupreous film will be deposited. Both copper and zinc may be discovered by sesquioxidating the iron by boiling the solution of the salt with nitric acid, and then precipitating the iron by an excess of ammonia. If the filtered solution be blue, copper is present; and if it contain zinc, this will be separated in flakes of white oxide, on expelling the excess of ammonia by ebullition. Sulphate of iron, when crystallized, consists of one eq. of acid 40·1, one of protoxide 36, and seven of water 63=139·1, and its formula is $\text{FeO}, \text{SO}_3 + 7\text{HO}$.

Medical Properties and Uses. Sulphate of iron is astringent and tonic. In large doses it is apt to produce nausea and vomiting, and griping of the bowels; and its use, when long continued, injures the stomach. It has been recommended as a remedy for the scrofulous diathesis, conjoined with extract of bark. As an astringent, it is given in diseases attended with immoderate discharges, such as passive hemorrhages, colliquative sweats, diabetes, chronic mucous catarrh, leucorrhœa, gleet, &c. As a tonic it is used in dyspepsia, and in the debility following protracted diseases. In amenorrhœa with deficient action, it is frequently resorted to with advantage, either alone, or conjoined with the fetid and stimulant gums. Externally the solution is occasionally used in chronic ophthalmia, leucorrhœa, and gleet, of various strengths, from one or two, to eight or ten grains of the salt to the fluidounce of water. The dose is from one to five grains in the form of pill. If given in solution, the water should be previously boiled to expel the air, which, if allowed to remain, would partially decompose the salt.

FERRI SULPHAS EXSICCATUM. *Ed.* *Dried Sulphate of Iron.*

“Expose any convenient quantity of Sulphate of Iron to a moderate heat in a porcelain or earthenware vessel, not glazed with lead, till it is converted into a dry grayish-white mass, which is to be reduced to powder.” *Ed.*

In this process, six eqs. out of seven of the water of crystallization of the salt are driven off. The heat should not exceed 212° , otherwise the salt itself would suffer decomposition. Dried sulphate of iron is used for making pills, the crystallized sulphate not being well adapted for this purpose. In prescribing dried sulphate of iron it is necessary to recollect that three grains are equivalent to five of the crystallized sulphate.

Off. Prep. Pilulæ Ferri Sulphatis, *Ed.*; Pil. Rhei et Ferri, *Ed.* B.

FERRI SULPHURETUM. *Ed.*, *Dub.* *Sulphuret of Iron.*

“The best Sulphuret of Iron is made by heating an iron rod to a full white heat in a forge, and rubbing it with a roll of sulphur over a deep vessel filled with water to receive the fused globules of Sulphuret which form.

An inferior sort, good enough, however, for pharmaceutic purposes, is obtained by heating one part of Sublimed Sulphur and three of Iron Filings in a crucible in a common fire till the mixture begins to glow, and then removing the crucible and covering it, until the action, which at first increases considerably, shall come to an end." *Ed.*

"Expose a rod of Iron to the strongest heat of a forge, until it becomes white-hot; and upon taking it from the fire, instantly apply it to a roll of sulphur. Receive the Sulphuret of Iron in water, separate it from sulphur, and having dried it, keep it in a well-stopped bottle." *Dub.*

Iron and sulphur form a number of sulphurets, among which the most important are the protosulphuret and sesquisulphuret, corresponding with the protoxide and sesquioxide of iron; the bi-sulphuret or *cubic pyrites*; and *magnetic pyrites*, which is a compound of five eqs. of protosulphuret, and one of bisulphuret. When the sulphuret is obtained by the application of solid sulphur to white-hot iron, the product corresponds in composition with magnetic pyrites; but when procured by heating flowers of sulphur with an excess of iron filings, as is directed in the second of the Edinburgh processes, a protosulphuret is generated mixed with metallic iron. When sulphur is applied to white-hot iron, the metal appears to become hotter, burns with scintillations in the vapour of the sulphur, and forms instantly the sulphuret, which, being comparatively fusible, melts into globules, and drops into the water, which serves to extinguish them. It is essential that the iron be raised to a white heat, for otherwise the process succeeds but imperfectly.

Properties, &c. The officinal sulphuret of iron has a yellowish colour and the metallic lustre. When obtained over water it is in the form of brownish-yellow globules, having a somewhat crystalline texture. When pure it furnishes a yellow powder, and dissolves in dilute sulphuric or muriatic acid without leaving a residue of sulphur, and with the production of hydrosulphuric acid gas (sulphuretted hydrogen), free from admixture of hydrogen. As prepared, however, by the officinal processes, it is not entirely soluble in dilute sulphuric acid, a portion of uncombined sulphur being left. The fused globules have the composition of $5\text{FeS} + \text{FeS}_2$, or, according to some, $5\text{FeS} + \text{Fe}_2\text{S}_3$. This preparation is employed exclusively as a pharmaceutical agent, for the production of hydrosulphuric acid gas. It may be made to yield this gas by the action of diluted sulphuric acid. During the reaction water is decomposed; its hydrogen combines with the sulphur to form the hydrosulphuric acid, while the oxygen converts the iron into protoxide, with which the sulphuric acid combines. *Hydrosulphuric acid* is a colourless gas, having a smell like that of putrid eggs. Its sp. gr. is 1.1782. It reddens litmus and saturates bases, forming salts called *hydrosulphates*, *sulphohydrates*, or *hydrosulphurets*. *B.*

FERRUM AMMONIATUM. U.S. FERRI AMMONIO-CHLORIDUM. Lond. Ammoniated Iron. Ammonio-chloride of Iron.

"Take of Subcarbonate of Iron *three ounces*; Muriatic Acid *ten fluid-ounces*; Muriate of Ammonia *two pounds and a half*; Distilled Water *four pints*. Mix the Subcarbonate of Iron with the Muriatic Acid in a glass vessel, and digest for two hours; then add the Muriate of Ammonia, previously dissolved in the Distilled Water, and, having filtered the liquor, evaporate to dryness. Rub the residue to powder." *U.S.*

The process of the *London College* is the same as the above, of which it was the original.

By the mutual action of muriatic acid and the sesquioxide of iron on the

subcarbonate, water and sesquichloride of iron are formed; and the solution of the latter, being evaporated along with that of the muriate of ammonia, yields a mixture of the two salts. If any carbonate of iron be present in the subcarbonate, a portion of protochloride of iron must also be formed; which, however, would probably be converted into sesquichloride during the operation. By the former process of the U. S. and Edinburgh Pharmacopœias, abandoned in the last edition of these works, a mixture of red oxide (sesquioxide) of iron and muriate of ammonia was submitted to sublimation. A portion of the muriate of ammonia was decomposed, the ammonia escaping, and the muriatic acid reacting upon the sesquioxide of iron so as to form water and sesquichloride of iron, the latter of which was sublimed with the undecomposed muriate of ammonia. By this mode of preparation the proportion between the two salts was variable. The present officinal plan has the double advantage of uniformity in the result, and greater facility in the process. There is no reason to believe that the sesquichloride of iron and muriate of ammonia are chemically combined in the preparation. According to Mr. Phillips, they are in the proportion of 15 parts of the sesquichloride to 85 of the muriate.

Properties. Ammoniated iron, as usually found in the shops, is in crystalline grains, of a yellow colour, a feeble odour, and a sharp styptic saline taste. It is entirely soluble in water and diluted alcohol, is deliquescent, and requires to be kept in well stopped bottles. By the alkalies and their carbonates, and by lime-water, it is decomposed, with the precipitation of about seven per cent. of sesquioxide of iron; and potassa in excess occasions the evolution of ammonia. Like the other chalybeates, it is incompatible with vegetable astringents.

Medical Properties and Uses. This preparation unites aperient properties with those belonging to the chalybeates generally, and is said to have been used with advantage in amenorrhœa, epilepsy, scrofula, rickets, &c.; but it is at best uncertain, and is now very seldom prescribed. The sublimed preparation was formerly employed under the names of *flores martiales*, and *ens martis*. From four to twelve grains may be given in the form of pill, electuary, or solution, several times a day.

Off. Prep. Tinctura Ferri Ammonio-chloridi. *Lond.*

W.

TINCTURA FERRI AMMONIO-CHLORIDI. *Lond.* *Tincture of Ammonio-chloride of Iron.*

“Take of Ammonio-chloride of Iron [Ammoniated Iron] *four ounces*; Proof Spirit *a pint* [Imperial measure]. Dissolve the Ammonio-chloride of Iron in the Spirit, and filter.” *Lond.*

This is simply a solution of the preceding preparation in diluted alcohol. It is feeble and uncertain as a chalybeate, and has no particular claims to attention.

W.

TINCTURA FERRI CHLORIDI. *U. S.* TINCTURA FERRI SESQUICHLORIDI. *Lond.* FERRI MURIATIS TINCTURA. *Ed.* MURIATIS FERRI LIQUOR. *Dub.* *Tincture of Chloride of Iron. Tincture of Muriate of Iron.*

“Take of Subcarbonate of Iron *half a pound*; Muriatic Acid *a pint*; Alcohol *three pints*. Pour the Acid upon the Subcarbonate of Iron, and shake the mixture occasionally for three days; then set it by that the dregs, if there be any, may subside; lastly, pour off the liquor, and add to this the Alcohol.” *U. S.*

“Take of Sesquioxide of Iron [Subcarbonate, *U. S.*] *six ounces*; Hydrochloric Acid *a pint* [Imperial measure]; Rectified Spirit *three pints* [Imp.

measure]. Pour the Acid upon the Sesquioxide of Iron in a glass vessel, and digest for three days, occasionally stirring. Then add the Spirit and filter." *London*.

"Take of Red Oxide [Subcarbonate] of Iron *six ounces*; Muriatic Acid (commercial) *one pint* [Imp. meas.]; Rectified Spirit *three pints* [Imp. meas.]. Add the Oxide to the Acid in a glass vessel; digest with a gentle heat, and occasional agitation, for a day, or till most of the Oxide be dissolved; then add the Spirit, and filter." *Ed.*

"Take of Rust of Iron *one part*; Muriatic Acid, Rectified Spirit, each *six parts*. Pour the Acid upon the Rust in a glass vessel, and shake the mixture occasionally for three days. Then set it by that the dregs may subside, and pour off the clear liquor. Evaporate this slowly to one-third, and when it is cold add the Spirit." *Dub.*

The subcarbonate of iron of the shops consists of sesquioxide of iron, mixed with a variable, but always small proportion of carbonate of the protoxide. When acted on by muriatic acid it is dissolved with effervescence, in consequence of the escape of carbonic acid; and a solution of the sesquichloride of iron, with a little protochloride is obtained. When the muriatic acid employed is of the officinal strength (sp. gr. 1.16), the quantity directed in the U. S. formula dissolves nearly all the precipitated carbonate, leaving behind, according to Mr. Phillips, less than one scruple, including accidental impurities. A reaction appears to take place between the muriatic acid and the alcohol, as the preparation has a decided ethereal odour. On exposure, the small quantity of protochloride of iron present is converted, by the absorption of oxygen, into sesquichloride and sesquioxide, the latter of which is precipitated unless there be an excess of muriatic acid present. In the U. S. formula no such excess exists, and the tincture may consequently deposit, upon standing, a little sesquioxide of iron, and become in the same proportion more feeble; but this is a very slight objection, and is easily obviated, if thought advisable, by adding sufficient muriatic acid to redissolve the precipitate. The London and Edinburgh preparations, which have a considerable excess of acid, are liable to the more serious objection of being thus rendered more irritant to the stomach. In the Dublin process there is a great waste of acid, of which much more is employed than is necessary to dissolve the quantity of rust of iron directed, the excess being driven off by heat. It is important that the apothecary should employ muriatic acid of the officinal specific gravity, as otherwise his preparation will be of uncertain strength. A want of attention to this circumstance is probably the cause that the tincture, as found in the shops, is very unequal. Of four specimens examined by Mr. Phillips, one contained in half a fluidounce 20 grains of sesquioxide of iron, another 12.1 grains, a third 11.3 grains, and the fourth only 9.3 grains. A specimen prepared by himself, precisely according to the directions of the former London Pharmacopœia, which are at present those of our own national standard, had the sp. gr. 0.994, and contained, in half a fluidounce, 16.8 grains of sesquioxide. The present London preparation, according to the same authority, has the sp. gr. 0.992, and contains in half a fluidounce nearly 15 grains of sesquioxide.

Properties. Tincture of chloride of iron is of a reddish-brown, somewhat yellowish colour, a sour and very styptic taste, and an odour resembling that of muriatic ether. The sesquichloride of iron, which results from its evaporation, is a deliquescent compound, of a dark orange colour, scarcely crystallizable, and consisting of two equiv. of iron 56, and three of chlorine $106.26 = 162.26$. The tincture is decomposed by the alkalies, alkaline earths, and their carbonates, astringent vegetable infusions, and the mucilage of gum Arabic, which produces with it a brown semitransparent

jelly. All these substances are, therefore, incompatible with it in prescriptions.

Medical Properties and Uses. This is one of the most active and certain preparations of iron, usually acceptable to the stomach, and much employed for all the purposes to which the chalybeates generally are applied. It has been particularly recommended as a tonic in scrofula, in which it was formerly often given, conjointly with the solution of chloride of calcium, or chloride of barium. It is supposed to be diuretic, and to have a peculiar influence on the urinary passages. Hence it has been employed in gleet, old gonorrhœa, and leucorrhœa; and is said to be useful in dysury dependent on spasmodic stricture of the urethra, in the dose of ten drops repeated every ten minutes, till some effect is experienced. In hemorrhages from the uterus, kidneys, and bladder, it is thought to act advantageously, but should be confined to those of a passive character, or employed only after sufficient depletion. Externally it has sometimes proved useful in the destruction of venereal warts, and as a styptic in cancerous and fungous ulcers. The dose is from ten to thirty minims, which may be gradually increased to one, or even two fluidrachms, two or three times a day. It is given diluted with water. W.

GUMMI-RESINÆ.

Gum-resins.

These are concrete natural juices of plants, obtained by spontaneous exudation or incision, and consisting of gum and resin, associated for the most part with more or less essential oil, and frequently with other substances, such as extractive, bassorin, starch, wax, and various salts. The gum and resin are essential ingredients, but exist in very different proportions in the different varieties. All the gum-resins are partially soluble in alcohol and in water, but completely so in neither of these liquids. Diluted alcohol, on the contrary, dissolves them almost entirely, especially if assisted by heat. With water they form an opaque emulsion; the resin, essential oil, and other insoluble constituents being held in suspension by the dissolved gum. They are to a certain extent soluble in vinegar. Upon several of them, especially myrrh and ammoniac, carbonate of potassa so reacts as to render them soluble in water, or capable of being permanently retained in suspension by that fluid.

The *London College* gives the following directions in relation to the gum-resins.

“Those GUM-RESINS are to be preferred, which may be chosen so perfect as not to require purification. But if they do not appear to be sufficiently pure, boil them in water until they soften, and express them through a hempen cloth; then set them by that the resinous part may subside. Pour off the supernatant liquid, and evaporate it by means of a water-bath, adding, towards the end of the process, the resinous portion, so as to incorporate it with the gum.

“The GUM-RESINS which melt easily, may be purified by putting them into an ox bladder, and holding them in boiling water, until they become so soft as to be capable of being separated from their impurities by expression through a hempen cloth.”

The first of these processes is applicable to the gum-resins only when they are intended for external use; for the essential oil, upon which their medicinal virtues often in great measure depend, is more or less dissipated by the heat employed. The latter process is preferable whenever practica-

ble, as it affects less the character of the medicine; but several of the gum-resins, such as assafetida and ammoniac, are not sufficiently fusible at the temperature of boiling water to admit of being strained with facility. It is always best to select those intended for internal exhibition, of such a quality as not to require purification. As they are usually brittle and pulverizable when very cold, they may be freed from the coarser impurities by powdering them in the winter season, and sifting the powder, which afterwards agglutinates with warmth. This plan is recommended by Mr. Brande, in relation to assafetida, ammoniac, and galbanum. The French pharmacu-
tists purify the gum-resins by dissolving them in diluted alcohol, filtering and evaporating the solution. This process, though liable in a still greater degree than that of the London College to the objection of diminishing the virtues of the medicine by driving off the essential oil, has the advantage of completely separating all insoluble substances, however minutely divided, such as fine sand or other earth, which might pass through the pores of a hempen strainer.

W.

HYDRARGYRUM.

Preparations of Mercury.

HYDRARGYRUM PURIFICATUM. *Dub. Purified Mercury.*

“Take of Mercury *six parts*. Draw off *four parts* by slow distillation.” *Dub.*

The mercury of commerce is usually sufficiently pure for pharmaceutical purposes; but occasionally it contains foreign metals, such as lead, tin, zinc, and bismuth, and hence the directions for its purification. Mercury being much more volatile than the contaminating metals, rises first in distillation, while they are left behind. But it is necessary to avoid pushing the distillation too far; for in that event, some of the foreign metals, particularly bismuth, are apt to be carried over. The Dublin College, on account of this danger, directs only two-thirds of the mercury to be drawn over; but to follow this direction causes waste. The distillation may be performed over a common fire, from an iron retort into water contained in a receiver. A wash-hand basin will answer as a receiver. As it is difficult and troublesome to purify mercury by distillation, it is better for the manufacturing chemist to purchase pure samples of the metal, which may be always had in the market, and thus supersede the necessity of this process. The U. S., London, and Edinburgh Pharmacopœias do not now include a formula for purifying mercury by distillation, but explain in their Notes, that the pure metal is intended by the term *Hydrargyrum*.

Properties, &c. Mercury is known to be pure when it is bright and perfectly mobile. Its freedom from foreign metals may be ascertained by the negative indications of the tests mentioned under *Hydrargyrum*. B.

HYDRARGYRI ACETAS. *Dub. Acetate of Mercury.*

“Take of Purified Mercury, Acetate of Potassa, each, *nine parts*; Diluted Nitric Acid *eleven parts*; boiling Distilled Water *one hundred parts*; Distilled Vinegar *a sufficient quantity*. Add the Nitric Acid to the Mercury, and when the effervescence shall have ceased, digest the mixture, so as to dissolve the metal. Dissolve the Acetate of Potassa in the Water, and add Distilled Vinegar until acidity predominates in the solution. To this, boiling hot, add the solution of the Mercury in the Nitric Acid, and strain the mixture quickly through a double linen cloth; then let it cool that crystals may form. Wash these with cold Distilled Water, and dry them on

paper with a very gentle heat. In every step of this process, glass vessels are to be used." *Dub.*

The object of this process is to obtain an acetate of the protoxide of mercury. By the solution of the metal in diluted nitric acid, in the proportion indicated, a nitrate of the protoxide is formed; and this, when added to the boiling solution of acetate of potassa, causes a double decomposition resulting in the formation of nitrate of potassa which remains in solution, and acetate of protoxide of mercury which precipitates in crystals as the solution cools. The nitric acid is used diluted in order to avoid deutoxidating the metal; and for the same reason heat is not applied until the action of the acid has ceased in the cold, and then only moderately. Notwithstanding every precaution, it is very difficult to get a perfect nitrate of protoxide of mercury; and as water throws down a yellow subnitrate from the nitrate of the deutoxide if the solutions be neutral, the College orders the solution of the acetate of potassa to be acidulated with distilled vinegar, which effectually prevents this precipitation. The straining of the solution, while hot, is intended to separate any subnitrate which may be accidentally formed. As the crystals of the acetate of mercury may be contaminated with a little nitrate of the deutoxide, which is rendered yellow by the action of water, some authorities recommend that the washing should be performed with water acidulated with distilled vinegar. The drying of the crystals is an operation which requires great care, as a slight heat is sufficient to decompose them. On this account it has been proposed to dry them by compression between the folds of bibulous paper.

Properties, &c. Acetate of mercury is a white salt, in the form of thin elastic scales of a pearly lustre. Its taste is very disagreeable, but less so than that of most of the other soluble salts of mercury. It is not affected by air, but contracts a brown tinge by exposure to light. It is insoluble in alcohol, but dissolves readily, with partial decomposition, in boiling water, from which, being only sparingly soluble in cold water, it precipitates in crystals on cooling. When it is a perfect acetate of the protoxide, alkalies throw down from its solution a black precipitate of protoxide; but if it be contaminated with acetate of the deutoxide, the same reagents cause a yellowish precipitate. It consists of one eq. of acetic acid 51·48, one of protoxide of mercury 210, and four of water 36=297·48.

Medical Properties. Acetate of mercury was introduced into regular practice, in consequence of its having been supposed to be the active ingredient in Keyser's pills, which were at one time esteemed to be a mild and safe antisyphilitic remedy, and the mode of preparing which was purchased and made public by the French government. These pills, however, are very unequal in their operation, and have been ascertained by Robiquet to contain the acetate of the deutoxide. The officinal acetate is intended to be an acetate of the protoxide; but even in this state it possesses no peculiar powers which give it advantages over other mercurials in the treatment of syphilis; and it is at present very little used. The dose is a grain, given in the form of pill, twice a day. It is occasionally used as an external application to cutaneous eruptions, in the proportion of a grain dissolved in a fluidounce of rose-water.

B.

HYDRARGYRI CHLORIDUM CORROSIVUM. *U.S.* HYDRARGYRI BICHLORIDUM. *Lond.* SUBLIMATUS CORROSIVUS. *Ed.* HYDRARGYRI MURIAS CORROSIVUM. *Dub.* *Corrosive Chloride of Mercury. Bichloride of Mercury. Corrosive Sublimate.*

"Take of Mercury two pounds; Sulphuric Acid three pounds; Chloride

of Sodium *a pound and a half*. Boil the Mercury with the Sulphuric Acid until the sulphate of mercury is left dry. Rub this, when cold, with the Chloride of Sodium, in an earthenware mortar; then sublime with a gradually increasing heat." *U. S.*

The London process is the same as the above.

"Take of Mercury *four ounces*; Sulphuric Acid (commercial) *two fluid-ounces and three fluidrachms*; Pure Nitric Acid *half a fluidounce*; Muriate of Soda *three ounces*. Mix the Acids; add the Mercury; dissolve it with the aid of a moderate heat; and then raise the heat so as to obtain a dry salt. Triturate this thoroughly with the Muriate of Soda, and sublime in a proper apparatus." *Ed.*

"Take of Persulphate of Mercury *five parts*; dried Muriate of Soda *two parts*. Rub them well together in an earthenware mortar, so as to reduce them to a very fine powder. Then, with a heat gradually raised, sublime the Corrosive Muriate of Mercury into a proper receiver." *Dub.*

In order to understand the above processes, which are the same in principle, it is necessary to premise, that corrosive sublimate is a bichloride of mercury, consisting of two eqs. of chlorine and one of mercury. By boiling sulphuric acid on mercury to dryness, a white salt is formed, which is a bisulphate of the deutoxide of mercury. (See *Hydrargyri Persulphas*.) When this is mixed with chloride of sodium (common salt), and the mixture exposed to a subliming heat, a mutual decomposition takes place. The chlorine of the common salt combines with the mercury, and sublimes as bichloride of mercury; while the sodium, oxygen of the deutoxide of mercury, and sulphuric acid unite to form sulphate of soda, which remains behind. The quantities for mutual decomposition are two eqs. of chloride of sodium, consisting of two eqs. of chlorine, and two of sodium; and one eq. of the bisulphate of the deutoxide of mercury, consisting of one eq. of mercury, two of oxygen, and two of sulphuric acid. The two eqs. of chlorine combine with the one eq. of mercury, to form one eq. of corrosive sublimate; and the two eqs. severally, of sodium, oxygen, and sulphuric acid, by their union, form two eqs. of dry sulphate of soda. The *Edinburgh* formula is very much changed from that previously given in the Latin Pharmacopœia. It is characterized by the small quantity of mercury taken, and by the use of nitric acid to assist the sulphuric in oxidizing the metal, according to the method pursued by the Dublin College in forming the *Hydrargyri Persulphas*. The *Dublin* formula is peculiar in ordering the bisulphate of the deutoxide of mercury ready formed, instead of preparing it as the first step of the process, as is done in the processes of the other Pharmacopœias. (See *Hydrargyri Persulphas*.)

The names given in the several Pharmacopœias to this chloride are, unfortunately, very various. It is called a chloride, as it is admitted to be, in the U. S. and London Pharmacopœias, a muriate, agreeably to an abandoned theory, in the Dublin, and corrosive sublimate, irrespective of chemical nomenclature, in the Edinburgh. We should be sorry to share the opinion of the Edinburgh College that the adoption of the modern chemical nomenclature, to express pharmaceutical substances, was a great error, on account of its liability to change. Systematic nomenclature belongs to science, and its change is the inevitable consequence of the progress of the latter. In respect to the London College name of *bichloride* for corrosive sublimate, we think it not sufficiently distinct from *chloride*, adopted by the same College for calomel. Hence we prefer the use of the adjunct, *corrosivum*, employed in the U. S. Pharmacopœia, as serving to fix attention to its deleterious nature.

Preparation on the Large Scale, &c. The first step is to form the bisulphate of the deutoxide of mercury, which is effected by heating the sulphuric acid and metal together in an iron pot, so arranged as to carry off the unwholesome fumes of sulphurous acid which are copiously generated. The dry salt obtained is then mixed with the common salt, and the mixture sublimed in an iron pot lined with clay, and covered by an inverted earthen pan. Recently Dr. A. T. Thomson of London, has taken out a patent for forming corrosive sublimate, on the large scale, by the direct combination, by combustion, of gaseous chlorine with heated mercury. The product is stated to be perfectly pure, and to be afforded at a lower price than the sublimate made in the usual way. In order that the combination may take place, the mercury need not be heated to its boiling point, but only to a temperature between 300° and 400° . (*Pharm. Journ. and Trans.* Sep. 1842.) It is sometimes useful to a physician to know how to make a small quantity of corrosive sublimate on an emergency. This may be done by dissolving deutoxide of mercury (red precipitate) in muriatic acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. In this case a double decomposition takes place, resulting in the formation of water and the bichloride.

Properties. Corrosive chloride of mercury, as obtained by sublimation, is in the form of colourless crystals, or, of white, semitransparent, crystalline masses, of the sp. gr. 5.2, permanent in the air, and possessing an exceedingly acrid, styptic, metallic, durable taste. It dissolves in a little less than twenty parts of cold water, and in three of boiling water. A boiling saturated solution, upon cooling, lets it fall in a confused mass of crystals. It is soluble also in two and a third parts of cold alcohol, in about its own weight of boiling alcohol, and in three parts of ether. Sulphuric, nitric, and muriatic acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapours, which condense, on cool surfaces, in white, shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum*.) The former precipitate is the hydrated deutoxide of mercury, and is formed in the process for preparing the *aqua phagedænica* of old pharmacy, which is obtained by mixing a drachm of corrosive sublimate with a pint of lime-water. Corrosive sublimate forms with muriate of ammonia and chloride of sodium, compounds which are more soluble than the uncombined mercurial salt. It is on this account that aqueous solutions of sal ammoniac, or of common salt dissolve much more corrosive sublimate than simple water. The combination of corrosive sublimate with muriate of ammonia was formerly called *sal alembroth*, or *salt of wisdom*. (See *Liquor Hydrargyri Bichloridi*.)

Corrosive sublimate has the property of retarding putrefaction in a remarkable degree. Animal matters, immersed in its solution, shrink, acquire firmness, assume a white colour, and become imputrescible. It is on account of this property that it is often usefully employed for the preservation of anatomical preparations.

Tests of Purity and Incompatibles. Pure corrosive chloride of mercury sublimes, when heated, without residue, and its powder is entirely and readily soluble in ether. Consequently, if a portion of any sample should not wholly dissolve in ether, or if it should not evaporate entirely, the presence of some impurity is proved. If calomel be present, it may be detected by its insolubility in water. Corrosive sublimate is incompatible with many of the metals, with the alkalies and their carbonates, with soap,

lime-water, tartar emetic, nitrate of silver, the acetates of lead, the sulphurets of potassa and soda, and all the hydrosulphates. It is also decomposed by many vegetable and some animal substances. According to Dr. Thomson (*London Dispensatory*), it produces precipitates in infusions or decoctions of the following vegetable substances;—chamomile, horse-radish, columbo, catechu, cinchona, rhubarb, senna, simaruba, and oak-bark. B.

Medical Properties and Uses. Corrosive sublimate is the most powerful of the mercurial preparations, operating quickly on the system, and, if not properly regulated, producing very violent effects. It is less apt to salivate than most other mercurials. In minute doses suitably repeated, it exerts its peculiar influence without any obvious alteration of the vital functions, except, perhaps, a slight increase in the frequency of the pulse, and in the secretions from the skin and kidneys. Sometimes, however, it purges; but this effect may be obviated by combining it with a little opium. In larger doses it occasions nausea, vomiting, griping pain in the bowels, diarrhœa, and other symptoms of gastric and intestinal irritation; and in still larger quantities produces all the effects of a violent corrosive poison. It has long been used as a remedy in syphilis, in all stages of which it is highly recommended by some authors. It is said to remove the symptoms more speedily than other mercurials, while its action is less unpleasant, as the mouth is less liable to be made sore. For the latter reason it is much employed by empirics, and is an ingredient in almost all those nostrums which have at various periods gained a temporary popularity as antivene-reals. But while it is extolled by some authors, others, among whom is Mr. Pearson of London, deny its extraordinary merits, and maintain that, though occasionally useful in arresting the progress of the complaint, particularly in the secondary stage, it does not produce permanent cures, and, in the primary stage, often fails altogether. The general opinion at present is in favour of its employment in secondary syphilis, and there can be no doubt that it occasionally does much good. It is also used advantageously in cutaneous diseases of a leprous character, and in obstinate chronic rheumatism. It is usually associated with alterative or diaphoretic medicines, such as the antimonials, and the compound decoction or syrup of sarsaparilla; and, in order to obviate the irritation it is apt to produce, it may often be advantageously united with opium, or extract of hemlock. There is no doubt that many of the substances in connexion with which it is employed, alter its chemical condition; but it does not follow that even in its altered state it may not be very useful as a remedy.

As an external remedy, corrosive sublimate is stimulant and escharotic. A very weak solution in water, containing from an eighth to half a grain in the fluidounce, is employed as an injection in gleet, as a gargle in venereal sorethroat, and as a collyrium in chronic venereal ophthalmia. A stronger solution, containing one or two grains in the fluidounce, is a very efficacious wash in lepra, and other scaly cutaneous eruptions. Dissolved in water, in the proportion of five or ten grains to the fluidounce, it may be used with much benefit in venereal ulcers of the throat, to which it should be applied by means of a camel's hair pencil. With lime-water it forms the *aqua phagedænica* of the older writers, employed as a wash for ill-conditioned ulcers. The powdered chloride has been used as an escharotic; but is, in general, inferior to nitrate of silver or caustic potassa. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of sulphate of zinc, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the necessity of resorting

to the knife avoided. This practice was first introduced, we believe, by the late Dr. Perkins of Philadelphia, and was highly recommended by Dr. Physick. We have employed it in several instances with complete success.

The dose of corrosive sublimate is from a twelfth to a quarter of a grain, repeated three or four times a day, and given in pill, or dissolved in water or spirit. The pill, which is the preferable form, is usually prepared with crumb of bread, and care should be taken that the medicine be equally diffused through the pilular mass, before it is divided. Mucilaginous drinks are usually given to obviate the irritating effects of the medicine.

Toxicological Properties. Swallowed in poisonous doses, it produces a sense of burning heat in the throat, excruciating pain in the stomach and bowels, excessive thirst, anxiety, nausea and frequent retching with vomiting of bloody mucus, diarrhœa and sometimes bloody stools, small and frequent pulse, cold sweats, general debility, difficult respiration, cramps in the extremities, faintings, insensibility, convulsions, and death. The mucous membrane of the stomach exhibits on dissection all the signs which mark the action of a violent corrosive poison. These symptoms are sometimes followed or conjoined with others indicating an excessive mercurial action upon the system, such as inflammation of the mouth and salivary glands, profuse salivation, fetid breath, &c. In the inferior animals, in whatever mode introduced into the system, corrosive sublimate is said to occasion irritation of the stomach and rectum, inflammation of the lungs, oppression of the brain, and depression if not inflammation of the heart. (*Christison.*) In the treatment of a case of poisoning by corrosive sublimate, Orfila recommends the free use of the whites of eggs beat up with water. The albumen of the eggs forms an insoluble and comparatively innocent compound with the corrosive sublimate; and the liquid by its bulk dilutes the poison, and distends the stomach so as to produce vomiting. It is, however, asserted by M. Lassaigne that this compound of albumen and corrosive sublimate, when recently precipitated, is soluble in acid and alkaline liquids, and in solutions of the chlorides of potassium, sodium, and calcium. (See *Journ. de Pharm.* xxiii. 510.) It is, therefore, important, at the same time that the antidote is used, to evacuate the stomach, before the newly formed compound can be again dissolved. If eggs cannot be procured, wheat flour mixed with water may be substituted, gluten having, according to M. Taddei, the same effect as albumen. Milk has also been recommended in consequence of the insoluble compound which casein forms with the poison. Besides the antidotes mentioned, Peruvian bark, meconic acid, protosulphuret of iron, and iron filings have been proposed, all of which have the property of decomposing corrosive sublimate. Should neither of these antidotes be at hand, mucilaginous drinks should be largely administered; and in any event, the patient should be made to drink copiously, so long as vomiting continues, or till the symptoms are relieved. Should he be unable to vomit, the stomach should be washed out by means of the stomach pump. The consecutive inflammation should be treated with general or local bleeding, fomentations, and cooling mucilaginous drinks, and the attendant nervous symptoms should be alleviated by opiates. W.

Tests for Corrosive Sublimate. On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations. The best tests for determining its mercurial nature, mentioned in the order of their delicacy, are ferrocyanuret of potassium, lime-water, carbonate of potassa, iodide of potassium, ammonia, sulphuretted hydrogen, and protochloride of tin. *Ferrocyanuret of potassium* gives rise

to a white precipitate (ferrocyanuret of mercury), becoming slowly yellowish, and at length pale-blue. *Lime-water* throws down a yellow precipitate of hydrated deutoxide. *Carbonate of potassa* causes a brick-red precipitate of carbonate of mercury. *Iodide of potassium* produces a very characteristic pale scarlet precipitate of biniodide of mercury. This precipitate frequently appears at first yellow. *Ammonia* gives rise to a fine, white, flocculent precipitate, the officinal ammoniated mercury or white precipitate. *Sulphuretted hydrogen* occasions a black precipitate of bisulphuret of mercury. The same effect is produced by hydrosulphate of ammonia. Finally, *protochloride of tin* causes at first a white precipitate (calomel), and afterwards a grayish-black one (mercury in a finely divided state), and, as a test, is not liable to any fallacy. Taking the results of Devergie, the relative delicacy of these tests may be expressed numerically as follows;—Ferrocyanuret of potassium $1\frac{1}{2}$; lime-water 4; carbonate of potassa 7; iodide of potassium 8; ammonia 36; sulphuretted hydrogen or hydrosulphate of ammonia 60; and protochloride of tin 80. To the above the following tests may be added, easily applied even by those unacquainted with chemistry. A *bright plate of copper*, immersed in a solution containing corrosive sublimate, is instantly tarnished, and, after the lapse of half an hour, becomes covered with a grayish-white powder. A *polished piece of gold*, moistened with the mercurial solution, and touched through the liquid with a piece of iron, contracts a white stain. This test, which was proposed by Mr. Sylvester and simplified by Dr. Paris, is conveniently applied by moistening with the suspected solution, a gold coin or ring, and touching it through the moistened spot with the point of a penknife. The object of the iron is to form with the gold a simple galvanic circle, which enables the latter metal to precipitate the mercury on its surface. Nearly all the above tests merely show the mercurial nature of the substance acted on. To determine whether the metal is united with chlorine, the mercurial liquid may be precipitated by lime-water, and the filtered solution, acidulated with nitric acid, then tested with nitrate of silver. If the mercury is in the state of chloride, the filtered solution will be one of chloride of calcium, which, with nitrate of silver, will yield a heavy white precipitate (chloride of silver), insoluble in nitric acid, but soluble in ammonia. The nitrate of silver may be added directly to the mercurial liquid; and if it contain corrosive sublimate, chloride of silver will fall, but probably mixed with calomel.

By the combined indications of the foregoing tests, corrosive sublimate may be infallibly detected, unless it exists in very minute quantity, associated with organic substances, by which its presence is often greatly obscured. When it exists in organic mixtures, made by boiling the contents or substance of the stomach in distilled water, Dr. Christison recommends that a preliminary trial be made with the protochloride of tin, on a small portion filtered for the purpose. If this causes a grayish-black colour, he shakes the mixture, as recommended by Orfila, with a fourth of its bulk of ether, which dissolves the chloride and rises to the surface. The ethereal solution is then evaporated to dryness, and the dry salt obtained is dissolved in hot water, whereby a pure solution is procured, in which the corrosive sublimate may be readily detected by the ordinary tests. If the trial test should produce a light gray colour, the chloride is indicated in still less quantity, and Dr. Christison recommends to proceed in the following manner. Treat the unfiltered mixture with protochloride of tin, as long as any precipitate is formed, which will have a slate-gray colour. Collect, wash, and drain it on a filter, and, having removed it without being dried, boil it, in a glass flask, with a moderately strong solution of caustic potassa, until all the

lumps disappear. The alkali will dissolve all animal and vegetable matter; and, on allowing the solution to remain at rest, a heavy grayish-black powder will subside, which consists chiefly of metallic mercury, and in which small globules of the metal may sometimes be discovered, by the naked eye, or by the aid of a magnifier.

LIQUOR HYDRARGYRI BICHLORIDI. *Lond.* *Solution of Bichloride of Mercury.*

"Take of Bichloride of Mercury [Corrosive Sublimate], Hydrochlorate of Ammonia, each, *ten grains*; Distilled Water *a pint* [Imperial measure]. Dissolve the Bichloride of Mercury and Hydrochlorate of Ammonia together in the Water." *Lond.*

This solution was intended to facilitate the dispensing of corrosive sublimate in small doses. The muriate of ammonia has been substituted for the alcohol formerly added to the solution, probably in order to prevent the decomposition of the bichloride. A solution of corrosive sublimate in water alone, under the influence of light, deposits calomel, while muriatic and chloric acids remain in the water, nor is this decomposition prevented by the addition of alcohol. The dose of the solution, of which a fluidounce contains half a grain of corrosive sublimate, is from one to four fluidrachms taken in flaxseed tea. W.

HYDRARGYRI CHLORIDUM MITE. *U. S.*, HYDRARGYRI CHLORIDUM. *Lond.* CALOMELAS. *Ed.* CALOMELAS SUBLIMATUM. *Dub.* *Mild Chloride of Mercury. Calomel.*

"Take of Mercury *four pounds*; Sulphuric Acid *three pounds*; Chloride of Sodium *a pound and a half*; Distilled Water *a sufficient quantity*. Boil two pounds of the Mercury with the Sulphuric Acid, until the sulphate of mercury is left dry. Rub this, when cold, with the remainder of the Mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the Chloride of Sodium, and rub it with the other ingredients till all the globules disappear; afterwards sublime. Reduce the sublimed matter to a very fine powder, and wash it frequently with boiling Distilled Water, till the washings afford no precipitate upon the addition of Solution of Ammonia; then dry it." *U. S.*

The *London* formula is the same as the above, except that the testing of the washings with ammonia, or any other reagent, is not directed.

"Take of Mercury *eight ounces*; Sulphuric Acid (commercial) *two fluidounces and three fluidrachms* [Imperial measure]; Pure Nitric Acid *half a fluidounce* [Imp. meas.]; Muriate of Soda *three ounces*. Mix the Acids, add four ounces of the Mercury, and dissolve it with the aid of a moderate heat. Raise the heat so as to obtain a dry salt. Triturate this with the Muriate of Soda and the rest of the Mercury till the globules entirely disappear. Heat the mixture by means of a sand-bath in a proper subliming apparatus. Reduce the sublimate to fine powder; wash the powder with boiling Distilled Water until the Water ceases to precipitate with solution of iodide of potassium, and then dry it." *Ed.*

"Take of Persulphate of Mercury *twenty-five parts*; Purified Mercury *seventeen parts*; Dried Muriate of Soda *ten parts*. Triturate together the Persulphate of Mercury and Purified Mercury, in an earthenware mortar, until the metallic globules completely disappear. Then add the dried Mu-

riate of Soda, and mix them well; and from a suitable vessel, with a heat gradually raised, sublime the mixture into a receiver. Reduce the sublimate to powder, and wash it with water so long as the decanted liquid is precipitated by Water of Caustic Potassa. Lastly, dry the Sublimed Calomel." *Dub.*

The object of the above processes, which all coincide in the principle on which they are conducted, is to obtain the protochloride of mercury. This chloride consists of one eq. of chlorine and one of mercury, and consequently contains precisely half as much chlorine as corrosive sublimate, combined with the same quantity of mercury. In the process of the U. S. Pharmacopœia, as in the case of corrosive sublimate, a bisulphate of the deutoxide is first formed; but instead of being immediately sublimed with the chloride of sodium, it undergoes a preparatory trituration with the same quantity of mercury as was employed in forming it. This trituration may be conceived to take place between one eq. of the bisulphate of the deutoxide, and one eq. of metallic mercury, which are thus converted into two equivalents of the monosulphate of the protoxide. This change will be easily understood, by adverting to the fact, that the bisulphate of the deutoxide consists of two eqs. of sulphuric acid, two of oxygen, and one of mercury, and when rubbed up with one additional eq. of mercury, the whole becomes two eqs. of acid, two of oxygen, and two of mercury, evidently corresponding with two eqs. of the monosulphate of the protoxide. The two eqs. of monosulphate thus formed, being heated with two eqs. of common salt, the two eqs. of chlorine in the latter sublime in union with the two eqs. of mercury in the former, and generate two eqs. of protochloride of mercury; while the two eqs. severally, of sulphuric acid, oxygen, and sodium, unite together to form two eqs. of dry sulphate of soda, which remain as a fixed residue. It is hence apparent that the residue in this process is the same as in that for corrosive sublimate.

The calomel in mass, as sublimed, is liable to contain a little corrosive sublimate; and hence the directions of the U. S. Pharmacopœia, to reduce the sublimed matter to a very fine powder, and to wash it with boiling distilled water until ammonia produces no precipitate with the washings. Ammonia occasions a white precipitate so long as the washings contain corrosive sublimate; and when it ceases to produce this effect, the operator may rest satisfied that the whole of the poisonous salt has been removed. The London College prescribes a careful washing, but omits in the formula any directions for testing for corrosive sublimate. The proper tests for ascertaining the purity of calomel are, however, enumerated in the "Notes," prefixed to the "Preparations."

The *Edinburgh* formula is peculiar in ordering a small proportion of nitric acid to assist the sulphuric acid in oxidizing the mercury, as is done also in the corrosive sublimate process. The washings are tested by iodide of potassium, which is not so delicate a test as ammonia. The *Dublin* process includes no directions for making the bisulphate of the deutoxide of mercury; because that salt, in the *Dublin* Pharmacopœia, is made by a separate formula, and designated by a distinct name, *persulphate of mercury*. It is, therefore, taken ready formed, mixed with the mercury and common salt in the usual way, and the mixture sublimed. The College has omitted to mention that the water used for washing should be boiling hot. The solution of caustic potassa, used to test the washings, is not so delicate a reagent as either iodide of potassium or ammonia.

Preparation on the Large Scale. The process for making calomel by means of the bisulphate of deutoxide of mercury, was originally practised at

Apothecaries' Hall, London. The proportions taken, and the mode of proceeding, in that establishment, are, according to Mr. Brande, as follows: 50 lbs. of mercury are boiled to dryness with 70 lbs. of sulphuric acid, in a cast iron vessel; and 62 lbs. of the dry salt formed are triturated with $40\frac{1}{2}$ lbs. of mercury till the globules disappear, and the whole is mixed with 34 lbs. of common salt. The mixture is then sublimed from an earthenware retort into an earthenware receiver, and the product is from 95 to 100 lbs. of calomel. The sublimate is next ground to an impalpable powder, and washed with a large quantity of distilled water.

The object of bringing calomel into a state of minute division, is more perfectly accomplished by the method of Mr. Joseph Jewell, of London, improved by M. Ossian Henry. It consists in causing the calomel in vapour to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate, in the same operation. Calomel made by this process, sometimes called Jewell's *hydrosublimate of mercury*, is free from all suspicion of containing corrosive sublimate, is much finer than when obtained by levigation and elutriation, and possesses more activity as a medicine. This kind of calomel is included in the French Codex under a distinct name (*mercure doux à la vapeur*), and is almost exclusively employed in England and France. M. Soubeiran of Paris, and M. Dann of Stuttgardt, have proposed to form an impalpable calomel by passing its vapour through a tube mixed with a current of air. M. Soubeiran states that his first attempts by this process have proved quite successful.

Properties. Mild chloride of mercury is a tasteless, inodorous substance, insoluble in water, alcohol, and ether, less volatile than corrosive sublimate, unalterable in the air, but blackening by long exposure to light. When in mass its form and appearance depend upon the shape and temperature of the subliming vessel. In this state, it is generally in the form of a white fibrous crystalline cake, soft and brittle, the interior surface of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7.2. The officinal form of this chloride is that of powder, in which state it always exists in the shops. The powder has a light buff or ivory colour, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, as is the case with Jewell's calomel, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black or covered with black paper. By the action of the alkalies or alkaline earths it immediately becomes black, in consequence of the formation of protoxide. (See *Hydrargyri Oxidum Nigrum*.) The composition of calomel has already been mentioned. The first European writer by whom it was described was Benguin, in 1608; but the researches of Mr. Hatchett seem to prove that it was long known and prepared in Thibet.

Tests of Purity and Incompatibles. Calomel, when pure, completely sublimes on the application of heat, and strikes a black colour, free from reddish tinge, by the action of the fixed alkalies. The buff colour indicates the absence of corrosive sublimate; but whiteness by no means shows the presence of impurity. Its freedom from the corrosive chloride may be determined by heating a small portion of it in distilled water, and then testing the water with ammonia, which will cause a white precipitate in case the water has taken up any of the chloride. In using this test it is best not to

boil the water on the calomel; as boiling water is said to convert it to a slight extent into corrosive sublimate. Besides being incompatible with the alkalis and alkaline earths, it is also decomposed by the alkaline carbonates, soaps, hydrosulphates, and, according to some authorities, by iron, lead, and copper. Agreeably to the experiments of M. Deschamps (*Journ. de Pharm.* xxv. 27), calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, bicianuret of mercury, and muriate of ammonia are formed; in the latter corrosive sublimate and bicianuret only. Hence this writer considers it very dangerous to associate calomel with bitter almonds in prescription. According to M. Mialhe calomel is in part converted into corrosive sublimate and metallic mercury by muriate of ammonia, and by the chlorides of sodium and potassium, even at the temperature of the body; and hence he believes that the conversion may take place in the *primæ viæ*. (*Journ. de Pharm.* xxvi. 108.) Popular belief coincides with M. Mialhe's views in regard to the power of common salt of increasing the activity of calomel. B.

Medical Properties and Uses. Calomel unites to the general properties of the mercurials those of a purgative and anthelmintic. It is the most valuable of the mercurial preparations, and in extent of employment is inferior to few articles of the *Materia Medica*. Whether the object is to bring the system under the general influence of mercury, or to produce its alterative action upon the hepatic or other secretory functions, calomel, on account both of its certainty and mildness, is preferred to all other preparations, with the single exception of the blue pill, which, though less certain, is still milder, and is sometimes preferably employed. When used with the above objects, the tendency to purge which it sometimes evinces, even in very small doses, must be restrained by combining it with opium. In sialagogue or alterative doses, it is often prescribed with other medicines, which, while they give it a direction to certain organs, have their own peculiar influence increased by its co-operation. Thus it renders squill more diuretic, nitre and the antimonials more diaphoretic, and seneka more expectorant.

As a purgative, calomel owes its chief value to its tendency to the liver, the secretory function of which it powerfully stimulates. It is usually slow and somewhat uncertain in its cathartic effect, and though itself but slightly irritating, sometimes occasions severe griping pain with bilious vomiting, attributable to the acrid character of the bile which it causes the liver to secrete. It is peculiarly useful in the commencement of bilious fevers, in hepatitis, jaundice, bilious and painters' colic, dysentery, especially that of tropical climates, and all other affections attended with congestion of the portal system, or torpidity of the hepatic vessels. The difficulty with which it is thrown from the stomach, renders it highly useful in some cases of obstinate vomiting, when other remedies are rejected. In the cases of children, it is peculiarly valuable from the facility of its administration; and in the febrile complaints to which they are subject, appears to exercise a curative influence, depending on some other cause than its mere purgative effect, and perhaps referable to its action upon the liver. In the treatment of worms it is one of the most efficient remedies, acting probably not only as a purgative, but also as an irritant to the worms, either by its immediate influence, or that of the acrid bile which it causes to flow. The slowness and uncertainty of its action, and its liability to salivate if too long retained in the bowels, render it proper either to follow or combine it with other cathartics, in order to ensure its purgative effect. When given

alone, it should be followed, if it do not operate in six or seven hours, by a dose of castor oil or sulphate of magnesia. The cathartics with which it is most frequently combined are jalap, rhubarb, aloes, scammony, colocynth, and gamboge. It is often added in small quantities to purgative combinations, with a view to its influence on the biliary organs.

In very large doses, calomel is supposed by some to act directly as a sedative, and with this view has been given in yellow and malignant bilious fevers, violent dysentery, malignant cholera, &c. The quantities which have been administered in such affections, with asserted impunity and even advantage, are almost incredible. A common dose is one or two scruples, repeated every half hour, or hour, or less frequently, according to the circumstances of the case. We have had no experience in this mode of administering calomel.

It is sometimes used as an errhine in amaurosis, mixed with twice its weight of sugar, or other mild powder; and in the same combination is occasionally employed to remove specks and opacity of the cornea. For this latter purpose, Dupuytren recommends particularly the calomel prepared according to the plan of Mr. Jewell. Calomel is also sometimes employed externally in herpetic, and other eruptions, in the shape of an ointment.

The dose as an alterative in functional derangement of the liver, is from half a grain to a grain every night, or every other night, followed in the morning, if the bowels are not opened, by a gentle saline laxative. When the stomach or bowels are very irritable, as in cholera and diarrhœa, from an eighth to a quarter of a grain may be given every hour or two, so as to amount to one or two grains in the course of the day. With a view to salivation, the dose is from half a grain to a grain three or four times a day, to be increased considerably in urgent cases. When large doses are given with this view, it is often necessary to combine them with opium. As a purgative, from five to fifteen grains or more may be given. Calomel has the peculiarity that its cathartic action is not increased in proportion to the dose, and enormous quantities have sometimes been given with impunity. In yellow fever, tropical dysentery, &c., from twenty grains to a drachm have been given and repeated at short intervals, without producing hypercatharsis; but this practice is justifiable only in cases of extreme urgency, in which the constitutional action of mercury as well as purgation is indicated. Even in very small doses of not more than one, two, or three grains, calomel purges some individuals briskly. In these persons, large doses, though they do not proportionably increase the evacuation, often occasion excessive spasmodic pain in the stomach and bowels. For children, larger doses are generally required in proportion than for adults. Not less than from three to six grains should be given as a purge to a child two or three years old, and this quantity often fails to act on the bowels, unless assisted by castor oil, or some other cathartic. Calomel may be given in pill made with gum Arabic and syrup, or in powder mixed with syrup or molasses.

CALOMELAS PRÆCIPITATUM. *Dub. Precipitated Calomel.*

“Take of Purified Mercury *seventeen parts*; Diluted Nitric Acid *fifteen*

parts. Pour the Acid upon the Mercury in a glass vessel; and when the mixture shall have ceased to effervesce, digest with a medium heat, with occasional agitation, for six hours. Then increase the heat that the liquor may boil for a short time, and afterwards pour it off from the residual Mercury, and quickly mix it with *four hundred parts* of boiling Water, containing *seven parts* of Muriate of Soda in solution. Wash the powder which subsides with warm Distilled Water, so long as the liquor decanted from it is precipitated by the addition of a few drops of Water of Caustic Potassa; lastly, dry it." *Dub.*

The method of forming calomel in the humid way, or by precipitation, was first proposed by Scheele. It consists of two steps; first, the formation of the nitrate of protoxide of mercury by dissolving the metal in weak nitric acid, and secondly, the decomposition of this salt by means of a hot solution of chloride of sodium (common salt). The nitric acid combines with sodium and the oxygen of the protoxide, so as to form nitrate of soda in solution, while the chlorine and mercury unite to form protochloride of mercury which precipitates. Though this process is sufficiently simple in theory, the performance of it is attended with some difficulty. It is necessary, in the first place, to prepare a pure nitrate of the protoxide, an object which is apt to miscarry, in consequence of the liability of the metal to become deutoxidized by the action of nitric acid. To guard against this result, weak nitric acid is employed, more mercury is ordered than the acid can dissolve, and a moderate heat applied, and that only after the effervescence has ceased. In the next place, the operator must guard against the precipitation of a subnitrate, which is always thrown down by the action of water upon the nitrate. To prevent the production of this impurity, it is necessary slightly to acidulate the nitric solution of the mercury with nitric acid, or the solution of common salt with muriatic acid; for an excess of acid in either of the solutions effectually prevents the formation of the subnitrate. This necessary precaution has been omitted in the directions of the Dublin College. The reason why the deutoxidation of the metal, and consequent production of binitrate of the deutoxide are to be avoided, is, that this salt, by double decomposition with the solution of chloride of sodium, generates corrosive sublimate. The production of corrosive sublimate in this way in the process will not injure the precipitated calomel, provided this be thoroughly washed; but it is objectionable as diminishing its quantity. When, however, the subnitrate is allowed to be formed, it contaminates the precipitated calomel, and, from its insolubility, cannot be separated by washing. As, notwithstanding every precaution, corrosive sublimate will be formed in this process, the liquor poured off from the precipitated calomel should be reserved for preparing *white precipitate*, as is done by the Dublin College. (See *Hydrargyrum Ammoniatum*.)

Properties, &c. Precipitated calomel, when properly prepared, scarcely differs in properties from sublimed calomel. It is stated to be whiter, smoother, and lighter than when obtained by sublimation. Another difference, according to Götting, is that it assumes a gray, while the sublimed calomel assumes a black colour, when triturated with lime-water. The presence of subnitrate may be detected by digesting the preparation in water containing a little nitric acid, and then testing the acid by an alkali, which will cause a precipitate, if any subnitrate has been taken up. Corrosive sublimate may be discovered in the manner stated under the head of sublimed calomel, page 987.

The medical properties of precipitated calomel are the same as those of

sublimed calomel. By some it is supposed to be more purgative. It is not used, and may be viewed as a superfluous preparation. B.

HYDRARGYRI CYANURETUM. *U.S.*, *Dub.* HYDRARGYRI BICYANIDUM. *Lond.* *Cyanuret of Mercury.* *Bicyanide of Mercury.* *Bicyanuret of Mercury.* *Prussiate of Mercury.*

"Take of Ferrocyanuret of Iron [Prussian blue] *four ounces*; Red Oxide of Mercury *three ounces* or a sufficient quantity; Distilled Water *three pints*. Put the Ferrocyanuret of Iron and three ounces of the Oxide of Mercury, previously powdered and thoroughly mixed together, into a glass vessel; and pour upon them two pints of the Distilled Water. Then boil the mixture, stirring constantly; and, if at the end of half an hour the blue colour remain, add small portions of the Oxide of Mercury, continuing the ebullition until the mixture becomes of a yellowish colour; after which, filter it through paper. Wash the residue in a pint of the Distilled Water, and filter as before. Mix the solutions, and evaporate till a pellicle appears; then set the liquor aside that crystals may form. To purify the crystals, dissolve them in Distilled Water, filter and evaporate the solution, and set it aside to crystallize." *U. S.*

"Take of Percyanide of Iron [Prussian blue] *eight ounces*; Binoxide of Mercury *ten ounces*; Distilled Water *four pints* [Imperial measure]. Boil them together for half an hour, and strain. Evaporate the liquor that crystals may form. Wash what remains frequently with boiling Distilled Water, and again evaporate the mixed liquors that crystals may form. Bicyanide of Mercury may be otherwise prepared by adding as much Binoxide of Mercury as will accurately saturate it to Hydrocyanic Acid, distilled from Ferrocyanide of Potassium with Diluted Sulphuric Acid." *Lond.*

"Take of Cyanuret of Iron [Prussian blue] *six parts*; Nitric Oxide of Mercury [red precipitate] *five parts*; Distilled Water *forty parts*. Mix the Cyanuret of Iron and Oxide of Mercury, and then add them to the Water previously warmed. Boil the mixture with constant stirring, for half an hour, and filter through bibulous paper. Wash the residue frequently with warm Distilled Water. Lastly, filter the liquors, and evaporate them, so that, upon cooling, crystals may form." *Dub.*

The above processes are essentially the same; their object being to present cyanogen and mercury to each other under favourable circumstances for combination. The compound formed consists of two eqs. of cyanogen, and one of mercury. It is, therefore, properly speaking, a bicyanuret. As Prussian blue is a compound of cyanogen and iron, the reaction which occurs is a case of double decomposition, resulting in the formation of bicyanuret of mercury, and a mixture of the protoxide and sesquioxide of iron. The reaction may be thus expressed; $2\text{Fe}_7\text{Cy}_9 + 9\text{HgO}_2 = 9\text{HgCy}_2 + 6\text{FeO} + 4\text{Fe}_2\text{O}_3$. This formula would be exact, if nothing remained but the oxides of iron; but in the residuum cyanogen appears to be present in an unknown state of combination. Taking the Prussian blue at the constant quantity of 4 parts, the *U. S. Pharmacopœia* uses 3, the *Dublin* 3·3, and the *London* 5 parts of the red precipitate. As Prussian blue is variable in quality, it is impossible to know beforehand how much oxide may be necessary to decompose it. Hence the *U. S. Pharmacopœia* very properly leaves the quantity to be determined in the progress of the process. Of course, the pure Prussian blue of the *U. S.* and *London Pharmacopœias* will require more of the red precipitate than the commercial Prussian blue of the *Dublin College*.

Winckler prepares the bicianuret of mercury by the following process. Mix 15 parts of ferrocyanuret of potassium in powder with 13 parts of concentrated sulphuric acid, and 100 parts of water. Distil the mixture to dryness into a receiver containing 30 parts of water. The ferrocyanuret is decomposed, sulphate of potassa is formed in the retort, and hydrocyanic acid distils over. Of the acid thus obtained reserve a portion, and mix the rest with 16 parts of red oxide of mercury in fine powder, and stir the mixture till the odour of hydrocyanic acid has entirely disappeared. Then decant the liquor and add for the purpose of saturating it, the portion of acid that had been reserved. This process gives 12 parts of the bicianuret. If the liquor were not treated with free hydrocyanic acid after having acted on the red oxide, it would probably contain some of this oxide in excess, and when evaporated would yield, instead of the bicianuret, a peculiar salt, composed of this cyanuret and the red oxide, which crystallizes in small acicular crystals. This process is substantially the same with the second process given by the London College.

Properties, &c. Cyanuret of mercury is a white substance, permanent in the air, and crystallized in anhydrous right square prisms, which are sometimes transparent, but usually white and opaque. It has a disagreeable styptic taste. It is but sparingly soluble in alcohol, but dissolves readily in cold water, and much more abundantly in hot. When acted on by muriatic acid, hydrocyanic acid is evolved, recognisable by its odour, and bichloride of mercury is left. When heated it yields cyanogen, and mercury remains behind. It acts on the animal economy as a potent poison. In medicinal doses it excites nausea and vomiting, and not unfrequently ptyalism, but does not produce epigastric pain like corrosive sublimate. It has been occasionally used as a remedy in syphilis, and is preferred by some practitioners to corrosive sublimate, as it does not give rise to pain, and as it is not decomposed by alkalies and certain organic matters, as corrosive sublimate is. The dose is from a sixteenth to an eighth of a grain or more. Its composition has been already given. For the properties and composition of cyanogen, see page 790.

Off. Prep. Acidum Prussicum, *Dub.*

B.

HYDRARGYRI IODIDUM. *U.S., Lond.* *Iodide of Mercury.*
Protiodide of Mercury.

“Take of Mercury *an ounce*; Iodine *five drachms*; Alcohol *a sufficient quantity*. Rub the Mercury and Iodine together, adding sufficient Alcohol to form a soft paste, and continue the trituration till the globules disappear. Then dry the Iodide in the dark, with a gentle heat, and keep it in a well stopped bottle from which the light is excluded.” *U.S.*

The *London* process is the original of the one above quoted.

The process above given for forming the protiodide of mercury is a case of simple combination, the alcohol facilitating the union by dissolving the iodine. This iodide is also prepared by precipitation, by adding a solution of iodide of potassium to one of the nitrate of protoxide of mercury; but as it is difficult to prepare the nitrate of the protoxide, without being mixed with some nitrate of deutoxide, the protiodide, when thus obtained, is apt to be contaminated with biniodide. A better way is to decompose calomel by iodide of potassium, in which case protiodide of mercury and chloride of potassium are formed, the latter of which may be removed by washing. The formula recommended by M. Boutigny is to mix twenty-nine drachms of calomel with twenty of pulverized iodide of potassium in a glass mortar, and to pour upon the mixture twelve ounces of boiling distilled water. After cooling, the liquid is decanted, and the precipitate washed on a filter with

distilled water, and dried in the shade. (*Amer. Journ. of Pharm.* viii. 326, from the *Bull. Gén. de Thérap.*)

Properties. This iodide is in the form of a greenish-yellow powder, insoluble in water, alcohol, or solution of chloride of sodium, but soluble in ether. Its sp. gr. is 7.75. When exposed to the light it is partially decomposed, and becomes of a dark olive colour. If quickly and cautiously heated, it sublimes in red crystals which afterwards become yellow. It is composed of one eq. of mercury 202, and one of iodine $126.3 = 328.3$. Its formula is HgI .

Medical Properties and Uses. Iodide of mercury has been given in scrofula and scrofulous syphilis. The dose is a grain daily, gradually increased to three or four. It is, however, chiefly employed in the form of ointment.

Off. Prep. Pilulæ Hydrargyri Iodidi, *Lond.*; Unguentum Hydrargyri Iodidi, *Lond.* B.

HYDRARGYRI IODIDUM RUBRUM. U.S. HYDRARGYRI BINIODIDUM. *Lond., Ed.* Red Iodide of Mercury. Biniodide of Mercury.

"Take of Corrosive Chloride of Mercury *an ounce*; Iodide of Potassium *ten drachms*; Distilled Water *two pints*. Dissolve the Chloride of Mercury in a pint and a half, and the Iodide of Potassium in half a pint of the Distilled Water, and mix the solutions. Collect the precipitate upon a filter, and, having washed it with Distilled Water, dry it with a moderate heat, and keep it in a well-stopped bottle." *U.S.*

"Take of Mercury *an ounce*; Iodine *ten drachms*; Alcohol *a sufficient quantity*. Rub the Mercury and Iodine together, adding the Alcohol gradually, until globules are no longer visible. Dry the powder with a gentle heat, and keep it in a well-stopped vessel." *Lond.*

"Take of Mercury *two ounces*; Iodine *two ounces and a half*; concentrated solution of Muriate of Soda *a gallon*. Triturate the Mercury and Iodine together, adding occasionally a little Rectified Spirit till a uniform red powder be obtained. Reduce the product to fine powder, and dissolve it in the solution of Muriate of Soda with the aid of brisk ebullition. Filter, if necessary, through calico, keeping the funnel hot. Wash and dry the crystals which form on cooling." *Ed.*

In the U.S. process for forming the red iodide of mercury, a double decomposition takes place between the corrosive sublimate and iodide of potassium, resulting in the formation of chloride of potassium which remains in solution, and biniodide of mercury which precipitates. The precipitate formed is soluble in the reacting salts, and hence a loss of part of it is incurred by an excess of either. It is best, however, to have a slight excess of the iodide of potassium, which is furnished by the proportion of the U.S. formula; as then the decomposition of the whole of the corrosive sublimate is insured, and any contamination of the biniodide by it prevented. The process of the London College is the same in principle as the U.S. and London processes for the protiodide; namely, the simple combination of the ingredients by trituration, with the aid of alcohol, a double proportion of iodine, of course, being taken. The Edinburgh College unites the ingredients of this iodide in the same manner; but after it is formed, the resulting mass is treated with a boiling solution of common salt, which dissolves the biniodide, to the exclusion of any contaminating protiodide; and the solution, thus obtained, on cooling, deposits the pure biniodide in crystals.

Properties. Biniodide of mercury is a scarlet-red powder, of the sp. gr. 6·3, insoluble in water, but soluble in alcohol, and in solutions of iodide of potassium, chloride of sodium, and of many of the mercurial salts. As obtained by the Edinburgh process, it is in splendid crimson acicular crystals. When heated it fuses readily into a yellow liquid, and sublimes in yellow rhombic scales, which become red on cooling. It forms definite compounds with the iodides of the alkaline metals. That formed with iodide of potassium has been used medicinally. (See *Iodo-hydrargyrate of Potassium* in the *Appendix*.) It consists of one eq. of mercury 202, and two of iodine $252 \cdot 6 = 454 \cdot 6$. Its formula is HgI_2 . It combines with the protiodide, so as to form a yellow *sesquiodide*, represented by the formula $\text{HgI} + \text{HgI}_2$ or Hg_2I_3 .

Medical Properties and Uses. Biniodide of mercury is a powerful irritant poison. It has been used in similar diseases with the protiodide, namely, in scrofula and syphilis, but is much more active. The dose is a sixteenth of a grain, gradually increased to a fourth, given in pill, or dissolved in alcohol.

HYDARGYRI OXIDUM NIGRUM. *U. S.* HYDRARGYRI OXYDUM NIGRUM. *Dub.* HYDRARGYRIOXYDUM. *Lond.* *Black Oxide of Mercury.*

“Take of Mild Chloride of Mercury [Calomel], Potassa, each, *four ounces*; Water *a pint*. Dissolve the Potassa in the Water, and when the dregs shall have subsided, pour off the clear solution. To this add the Chloride of Mercury, and stir them constantly together till the Black Oxide is formed. Having poured off the supernatant liquor, wash the Black Oxide with Distilled Water, and dry it with a gentle heat.” *U. S.*

“Take of Sublimed Calomel *one part*; Water of Caustic Potassa, heated, *four parts*. Rub them together until an oxide of a black colour is obtained. Wash this frequently with water, and dry it upon bibulous paper with a *medium heat*.” *Dub.*

“Take of Chloride of Mercury [Calomel] *an ounce*; Lime-water *a gallon* [Imperial measure]. Mix and frequently shake them. Set aside the mixture, and when the Oxide shall have subsided, pour off the liquor. Lastly, wash it in Distilled Water till nothing alkaline can be perceived, and, having wrapped it in bibulous paper, dry it in the air.” *Lond.*

The object of these processes is to obtain the protoxide or black oxide of mercury, which was at one time believed to be the active constituent of those preparations in which the metal is minutely divided by trituration. The U. S. and Dublin processes afford the protoxide in a purer state than the London. The two former are essentially the same. In both, calomel is completely decomposed by the solution of potassa; its chlorine being converted by union with potassium into chloride of potassium, which remains in solution, while the mercury unites with the oxygen of the potassa to form protoxide of mercury which subsides. More potassa is employed than by calculation would seem to be requisite; but it has been ascertained by experiment, that a considerable excess is necessary for the complete decomposition of the calomel. In the U. S. process, however, the quantity is, perhaps, unnecessarily large; being more than double the proportion contained in the “water of caustic potassa,” directed by the Dublin College. The use of the officinal solution of potassa is preferable, on the score of economy, to that of a solution extemporaneously prepared from the caustic alkali. In order to ensure the success of the process, the calomel, very finely levi-

gated, should be rubbed quickly with the alkaline solution in a mortar, and the resulting oxide should be dried in the dark with a very gentle heat, as it is decomposed by the agency both of light and of an elevated temperature. For the same reason it should be preserved in an opaque bottle. This mode of preparing the black oxide of mercury was introduced into use by Mr. Donovan.

In the London process, the reaction takes place between calomel and lime-water. An interchange of principles takes place; the calcium of the lime taking the chlorine of the calomel to form chloride of calcium, which remains in solution, and the mercury uniting with the oxygen of the lime to form protoxide of mercury, which subsides. But it is extremely difficult completely to decompose calomel in this manner, on account of the obstacle which its insolubility and the dilute nature of the solution of lime presents to that close contact of particles which is essential to the chemical reaction of different bodies on each other. Hence the protoxide, in this preparation, is almost always mixed with a portion of calomel, which is greater or less, according to the care with which the process has been conducted. When the proportion is large, the powder has a grayish colour; when very small, it scarcely differs in appearance or properties from the U. S. and Dublin oxide. From the uncertainty of its composition, it should be discarded from use.

The oxide may also be prepared by decomposing a solution of the nitrate of protoxide of mercury by the solution of potassa. This nitrate may be obtained by treating twenty parts of mercury with eighteen parts of nitric acid of 25° Baumé, adding, when nitrous vapours cease to rise, ten parts of warm distilled water, boiling for a short time, decanting the clear liquor, and setting it aside to crystallize. The mother waters by evaporation will furnish a new product of crystals of protonitrate. (*Ratier's Pharm. Franç.*) The preparation, formerly official in the Dublin Pharmacopœia under the name of *Pulvis Hydrargyri Cinereus*, made by adding carbonate of ammonia to a solution of mercury in heated nitric acid, was a mixture of subnitrate of mercury and ammonia with the protoxide of mercury.

Properties, &c. As first prepared, this oxide is greenish-black; but as found in the shops it is almost always of an olive colour, owing, it is supposed, to the chemical changes which it undergoes. It is inodorous, tasteless, and insoluble in water and alkaline solutions; and consists of one equiv. of mercury 202, and one equiv. of oxygen 8=210. On exposure to light or heat it is decomposed, one part assuming the metallic state, in consequence of the loss of its oxygen, which converts another part into the deutoxide. The preparation, therefore, becomes a mixture of the protoxide, the deutoxide, and metallic mercury, with which calomel is sometimes associated, in consequence of the incomplete decomposition of that originally employed in the process. By a strong heat it is completely dissipated, and metallic globules are sublimed. When pure it is soluble in acetic and nitric acids, and entirely insoluble in muriatic acid, which forms with it water and calomel. If it contain the deutoxide, this is dissolved by muriatic acid, and may be detected in the solution by the production of a white precipitate with water of ammonia, and of a yellow one with solution of potassa. Calomel, if present, may be discovered by boiling the powder with a solution of potassa, thus forming chloride of potassium, which, when the solution is saturated with nitric acid, will afford a white precipitate of chloride of silver on the addition of nitrate of silver. (*Phillips.*)

Medical Properties and Uses. The black oxide is alterative, sialagogue, and purgative. It may be employed for the same purposes with calomel, over

which, however, it has not in our hands exhibited any superiority, while, from the occasional presence of the deutoxide, it must be liable to operate harshly. The idea under which it was introduced into use, that it was the basis of the blue pill, is probably erroneous. Made into an ointment with lard, according to the process of Donovan, it may be applied externally with good effect in bringing the system under the mercurial influence. (See *Unguentum Hydrargyri*.) Its dose as an alterative is one-fourth or half a grain daily, as a sialagogue from one to three grains two or three times a day, given in the form of pill. It was employed by Mr. Abernethy for mercurial fumigation; the patient being placed, covered with under garments, in a vapour-bath, and exposed for fifteen or twenty minutes to the vapours arising from two drachms of the oxide, put upon heated iron within the bath. W.

HYDRARGYRI OXIDUM RUBRUM. *U.S., Ed.* HYDARGYRI TRICO-OXYDUM. *Lond.* HYDRARGYRI OXYDUM NITRICUM. *Dub.* *Red Oxide of Mercury. Red Precipitate.*

“Take of Mercury, *thirty-six ounces*; Nitric Acid *fourteen fluidounces*; Water *two pints*. Dissolve the Mercury, with a gentle heat, in the Acid and Water previously mixed together, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel till red vapours cease to rise.” *U. S.*

“Take of Mercury *three pounds*; Nitric Acid *a pound and a half*; Distilled Water *two pints* [Imperial measure]. Mix in a suitable vessel, and apply a gentle heat till the Mercury is dissolved. Boil down the solution; and rub the residue into powder. Put this into another very shallow vessel; then apply a gentle fire, and gradually increase it, till red vapour ceases to rise.” *Lond.*

“Take of Mercury *eight ounces*; Diluted Nitric Acid (D. 1·280) *five fluidounces* [Imperial measure]. Dissolve half of the Mercury in the Acid with the aid of a moderate heat; and continue the heat till a dry salt is formed. Triturate the rest of the Mercury with the salt till a fine uniform powder be obtained; heat the powder in a porcelain vessel and constantly stir it, till acid fumes cease to be discharged.” *Ed.*

“Take of Purified Mercury *two parts*; Diluted Nitric Acid *three parts*. Dissolve the Mercury, and let heat be applied until the dried mass is converted into red scales.” *Dub.*

In these processes the mercury is first oxidized at the expense of a portion of the nitric acid, the remainder of which unites with the oxidized metal to form either the nitrate of the deutoxide of mercury, or a mixture of this with the nitrate of the protoxide. The resulting mass when exposed to a strong heat is decomposed, giving out red nitrous fumes, and assuming successively a yellow, orange, and brilliant purple-red colour, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the protoxide of the protonitrate, if any be present, is converted into deutoxide, while nitric oxide gas escapes, and takes the form of nitrous acid vapour on contact with the air. The deutoxide of mercury is left behind, but in general not entirely free from the nitrate, which cannot be wholly decomposed by heat, without endangering the decomposition of the oxide itself, and the volatilization of the metal. The preparation is, in common language, called *red precipitate*. The name of *red oxide of mercury*, by which it is designated in the U. S. Pharmacopœia, is appropriate, as the nitrate of mercury exists merely as an in-

cidental impurity; and there is no occasion to distinguish the preparation from the pure deutoxide obtained by calcining mercury, as the latter is not recognised in our Pharmacopœia, and is never employed in this country.

In the preparation of this mercurial, various circumstances influence in some measure the nature of the product, and must be attended to, if we desire to procure the oxide with that fine bright orange-red colour, and shining scaly appearance, which are usually considered desirable. Among these circumstances is the condition of the nitrate of mercury submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in the U. S., London and Edinburgh processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep orange colour. Care must also be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. M. Payssé, who paid great attention to the manufacture of red precipitate, recommended 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia, that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé, to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more would be useless. It is not necessary that the salt should be removed from the vessel in which it is formed; and it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A matrass may be used with a large flat bottom, so that an extended surface may be exposed, and all parts heated equally. The metal and acid having been introduced, the matrass should be placed in a sand-bath, and covered with sand up to the neck. The solution of the mercury should be favoured by a gentle heat, which should afterwards be gradually increased till red vapours make their appearance, then maintained as equably as possible till these vapours cease, and at last slightly elevated till oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the matrass, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide, and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the matrass being still allowed to remain in the sand-bath. These last precautions are said to be essential to the fine red colour of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more steadily and uniformly maintained. The direction of the Edinburgh College to rub a portion of mercury with the nitrate before decomposing it, renders the process more economical, as the nitric acid which is dissipated is thus employed in oxidizing an additional quantity of the metal.

As the process is ordinarily conducted in chemical laboratories, the nitrate of mercury is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand in the chamber of an oven or furnace provided with a flue for the escape of the vapours. Each vessel may conveniently contain ten pounds of the nitrate. There is always some loss in the operation conducted in this way.

Properties, &c. Red precipitate, when well prepared, has a brilliant red colour with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Dr. Barker found 1000 parts to take up only 0.62 of the oxide. Dr. Christison found 1 part of the oxide

to be dissolved by about 7000 parts of boiling water, and the solution to give a black precipitate with sulphuretted hydrogen. Nitric and muriatic acids dissolve it without effervescence. At a red heat it is decomposed and entirely dissipated. It is essentially the deutoxide (peroxide) of mercury, consisting of one equivalent of the metal 202, and two of oxygen 16=218; but, in its ordinary state, it always contains a minute proportion of nitric acid, probably in the state of subpernitrate. According to Brande, when rubbed and washed with a solution of potassa,edulcorated with distilled water, and carefully dried, it may be regarded as nearly pure deutoxide. It is said to be sometimes adulterated with brickdust, red lead, &c.; but these may be readily detected, as the oxide of mercury is wholly dissipated if thrown upon red hot iron. The disengagement of red vapours when it is heated, indicates the presence of nitrate of mercury. The same or some other saline impurity would be indicated, should water, in which the oxide has been boiled, afford a precipitate with lime-water.

Medical Properties and Uses. This preparation is too harsh and irregular in its operation for internal use, but is much employed externally as a stimulant and escharotic, either in the state of powder or of ointment. In the former state it is sprinkled on the surface of chancres, and indolent, flabby, or fungous ulcers; and mixed with 8 or 10 parts of finely powdered sugar is sometimes blown into the eye to remove opacity of the cornea. The powder should be finely levigated. The ointment is officinal. (See *Unguentum Hydrargyri Oxidi Rubri.*)

Off. Prep. Hydrargyri Cyanuretum. *U. S., Dub.;* Unguentum Hydrargyri Oxidi Rubri, *U. S., Lond., Ed., Dub.* W.

HYDRARGYRI OXYDUM RUBRUM. *Dub. Red Oxide of Mercury. Precipitate per se. Calcined Mercury.*

“Take of Purified Mercury *any quantity.* Put it into an open glass vessel, with a narrow mouth and broad bottom, and expose it to a heat of about 600°, till it is converted into red scales.” *Dub.*

As mercury requires for its oxidation a temperature little short of its boiling point, it is necessary that the vessel in which it is heated be so constructed as to prevent the escape of the vapour which rises during the process. A glass matrass is usually employed, having a narrow neck, drawn out at top into an almost capillary orifice. But the arrangement which serves to confine the mercurial vapour, impedes also the free access of air, so that the process is exceedingly tedious. The mercury introduced should not be more than sufficient to cover the bottom of the vessel, which should be heated by means of a sand-bath till vapours begin to rise. These are condensed in the upper part of the matrass, and, by maintaining the temperature steadily at this point, a constant circulation of vapour is kept up within the vessel. The metal very slowly combines with the oxygen, forming first a black, and then a red powder, molecules of which begin to appear after some days, and gradually increase till they cover the surface of the mercury. Care must be taken not to increase the heat too much, as not only is the mercury thus volatilized, but the oxide already formed is decomposed. Several weeks are requisite for the complete oxidation of a small portion of metal, and the process is necessarily expensive. The preparation is the *hydrargyrum præcipitatum per se*, or *precipitate per se* of the older chemical writers.

Properties, &c. It is in minute, sparkling, crystalline scales, of a deep red colour becoming still deeper by heat, inodorous, of an acrid taste, very slightly soluble in water, and freely soluble in nitric, muriatic, and some

other acids. Its aqueous solution changes the infusion of violets to green. It consists of one equiv. of mercury 202, and two of oxygen 16=218, and is therefore a deutoxide. It is sometimes also called *binoxide* or *peroxide of mercury*. At a red heat it is decomposed, oxygen being given off, and the mercury revived. Its solutions in the acids afford, with potassa and soda, an orange-coloured precipitate of deutoxide, and with ammonia a white precipitate, consisting of the acid, deutoxide, and ammonia. Its high price affords an inducement for adulteration, to avoid which it should be kept in the crystalline state. If pure, it is wholly volatilized by a red heat.

Medical Properties and Uses. It has the general properties of the mercurial preparations, but is apt to vomit and purge, and to act otherwise violently on the stomach and bowels. Though formerly used in the treatment of syphilis, it has been entirely abandoned. It has been employed externally for the same purposes with the red precipitate; but is much more costly, without having any superiority. In this country it is almost unknown as a medicine. The dose may be from one-sixth of a grain to a grain.

W.

HYDRARGYRI BINOXYDUM *Lond. Binoxide of Mercury.*

"Take of Bichloride of Mercury [corrosive sublimate] *four ounces*; Solution of Potassa *twenty-eight fluidounces* [Imperial measure]; Distilled Water *six pints* [Imperial measure]. Dissolve the Bichloride of Mercury in the Water, filter, and add the Solution of Potassa. Having poured off the liquor, wash the precipitated powder in distilled water, till nothing alkaline can be perceived, and dry it with a gentle heat." *Lond.*

This preparation is chemically identical with the preceding, though somewhat different from it in appearance. The process was introduced by the London College into the last edition of their Pharmacopœia, as a substitute for the much more tedious one of oxidizing the mercury by the combined action of air and heat. When a solution of bichloride of mercury is mixed with a solution of potassa, a mutual interchange of principles takes place—the two equivalents of chlorine seizing upon two equiv. of potassium to form two equiv. of chloride of potassium, which remains in solution; while the liberated equivalent of mercury combines with the two liberated equivalents of oxygen, constituting the deutoxide or binoxide of mercury, which is deposited.

Thus prepared, the binoxide of mercury is in the form of an orange-red impalpable powder, having the essential properties of the *precipitate per se*. According to Phillips, if it be of a brownish colour, the solution of potassa employed was deficient either in quantity or strength, and the preparation contains oxychloride of mercury. If upon being dissolved in nitric acid and treated with nitrate of silver it afford a precipitate, the presence of a portion of undecomposed bichloride may be suspected.

This preparation has the same medical properties, and may be employed for the same purposes and in the same doses as that last described. (See *Hydrargyri Oxydum Rubrum*.)

Off. Prep. Hydrargyri Bicyanidum, *Lond.*

W.

HYDRARGYRI PERSULPHAS. *Dub. Persulphate of Mercury.*

"Take of Purified Mercury, Sulphuric Acid, each, *six parts*; Nitric Acid *one part*. Expose them to heat in a glass vessel, and increase the heat until the mass becomes white and perfectly dry." *Dub.*

Cold sulphuric acid has no action on mercury, but when an excess of acid is boiled to dryness upon the metal, it is deutoxidized at the expense

of part of the acid, sulphurous acid is copiously evolved, and the deutoxide formed unites with the undecomposed portion of the sulphuric acid, so as to form the bisulphate of the deutoxide of mercury, which is the persulphate of the Dublin College. In the Dublin formula, the oxidation of the metal is assisted by a small portion of nitric acid, the use of which, though not essential to the result, is stated by Dr. Barker to facilitate and shorten the process, and to afford a much whiter salt than when sulphuric acid alone is employed. When nitric acid is used, orange-coloured fumes are given off on the first application of heat, and the acid is totally decomposed.

Persulphate of mercury, as obtained by a separate formula, is peculiar to the Dublin Pharmacopœia; but it is formed as the first step of the processes of the other Pharmacopœias for preparing corrosive sublimate, calomel, and turpeth mineral. The adoption of a separate formula and distinct official name for this salt, is certainly an improvement on the part of the Dublin College; as it obviates the necessity of repeating the directions for obtaining the same substance in several distinct formulæ. On account of its important uses, it requires to be made on a large scale by the manufacturing chemist, and the process is generally performed in a cast-iron vessel, which should be conveniently arranged for the escape and decomposition of the sulphurous acid fumes, which otherwise become a serious nuisance to the neighbourhood. The best way to effect this purpose is to allow them to pass off through a very lofty chimney mixed with abundance of coal smoke.

Properties, &c. Persulphate of mercury is in the form of a white saline mass. It consists of two eqs. of acid 80.2 and one of deutoxide of mercury $218 = 298.2$. It has no medical uses.

Off. Prep. Calomelas Sublimatum, *Dub.*; Hydrargyri Murias Corrosivum, *Dub.*; Hydrargyri Oxydum Sulphuricum, *Dub.* B.

HYDRARGYRI SULPHAS FLAVUS. U.S. HYDRARGYRI OXYDUM SULPHURICUM. *Dub.* *Yellow Sulphate of Mercury. Turpeth Mineral.*

“Take of Mercury *four ounces*; Sulphuric Acid *six ounces*. Mix them in a glass vessel, and boil by means of a sand-bath till a dry white mass remains. Rub this into powder, and throw it into boiling water. Pour off the supernatant liquor, and wash the yellow precipitated powder repeatedly with hot water; then dry it.” U.S.

“Take of Persulphate of Mercury *one part*; warm Water *twenty parts*. Rub them together in an earthenware mortar, and pour off the supernatant liquor. Wash the yellow powder with warm Distilled Water, so long as the decanted liquor is precipitated by the addition of a few drops of the Water of Caustic Potassa. Lastly, dry the Sulphuric Oxide of Mercury.” *Dub.*

By referring to the articles on corrosive sublimate and calomel, it will be found that the peculiar salt which is generated by boiling sulphuric acid on mercury to dryness, is directed to be obtained as the first step for obtaining these chlorides; and here it is perceived that in the U. S. formula, the same salt is again directed to be formed. The Dublin College has very properly avoided these repetitions, by adopting a distinct formula and name for the salt in question. We have already mentioned that this salt is the bisulphate of the deutoxide of mercury. When it is thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is the turpeth mineral. According to Berzelius, turpeth mineral is a basic sesquisulphate of the deutoxide of mercury, and the

supernatant solution contains a supersulphate, consisting of six eqs. of acid and one of base. The same composition for turpeth mineral is given by Gay-Lussac; and its accuracy has been recently verified by an analysis by Dr. Kane of Dublin. (See *Pharm. Journ. and Trans.* for August 1842.) The composition above given of turpeth mineral implies the decomposition of four eqs. of the bisulphate of the deutoxide, and the manner in which the reaction takes place is shown by the following equation;— $4(\text{HgO}_2, 2\text{SO}_3) = \text{turpeth mineral } (3\text{HgO}_2 + 2\text{SO}_3) + \text{supersulphate } (\text{HgO}_2 + 6\text{SO}_3)$.

Properties, &c. Yellow sulphate of mercury is in the form of a powder of a lemon-yellow colour, and possessing a somewhat acrid taste. It dissolves in 2000 parts of cold water, and in about 600 parts of boiling water. When exposed to a moderate heat, it becomes first red and afterwards brownish-red, but regains its original colour on cooling. (*Barker.*) At a red heat it is decomposed and dissipated, sulphuric acid being evolved, and metallic globules sublimed. It was originally called *turpeth mineral*, from the resemblance of its colour to that of the root of the *Ipomœa Turpethum*, a plant formerly used in medicine. Its composition is given above.

Medical Properties and Uses. Turpeth mineral is alterative, and powerfully emetic and errhine. As an alterative, it has been given in leprosy disorders and glandular obstructions. It has been employed with benefit as an emetic, repeated every few days, in chronic enlargements of the testicle; but it often operates with great violence, and is apt to excite severe pytalism. It proves useful in these cases upon the principle of revulsion, and by imparting activity to the absorbents. As an errhine, it has been used with advantage in chronic ophthalmia, and in diseases of the head; and it sometimes produces salivation when thus employed. The dose, as an alterative, is from a quarter to half a grain; as an emetic, from two to five grains. When employed as an errhine, one grain may be mixed with five grains of starch or powdered liquorice root. B.

HYDRARGYRI SULPHURETUM NIGRUM. *U.S., Dub.* HYDRARGYRI SULPHURETUM CUM SULPHURE. *Lond.* *Black Sulphuret of Mercury.* *Sulphuret of Mercury with Sulphur.* *Ethiops Mineral.*

“Take of Mercury, Sulphur, each, a pound. Rub them together till all the globules disappear.” *U.S.*

The *London* and *Dublin* formulæ are similar to the above. The *Dublin* College merely adds that the trituration should be performed in a stone-ware mortar.

Mercury and sulphur have a strong affinity for each other; as is shown by the fact, that when they are triturated together in quantities, the mixture grows hot, cakes, and exhales a sulphureous odour. When rubbed together in equal weights, as directed in the *Pharmacopœias*, they are supposed to unite chemically; but the proportion of sulphur is much greater than is necessary to form a definite compound. Only two sulphurets of mercury have been admitted by the generality of chemists, a protosulphuret, and a bisulphuret or cinnabar; and the quantity of sulphur, directed in the *Pharmacopœias*, is much more than sufficient to form even the latter. Thus, it still remains an unsettled point, what is the exact nature of the officinal black sulphuret, or *ethiops mineral*. Mr. Brande, from his experiments, considers it to be a bisulphuret mixed with sulphur. Thus he found, that when boiled repeatedly in a solution of potassa, sulphur was dissolved, and

a black insoluble powder was left, which sublimed without decomposition, and gave a substance having all the characters of cinnabar.

Ethiops mineral is sometimes obtained by melting the sulphur in a crucible, and adding the mercury to it; but when thus prepared, the sulphur is apt to become acidified, and the preparation to acquire an activity which does not belong to it when obtained by trituration. The latter method, accordingly, should always be employed.

Properties, &c. Black sulphuret of mercury is a heavy, tasteless, insoluble, black powder. When exposed to heat, it becomes of a dark violet colour, emits the excess of sulphur in sulphurous acid fumes, and sublimes in brilliant red needles without residue. If charcoal be present, it will remain behind. When well prepared, no globules of mercury should be discernible in it when viewed with a magnifier; and if rubbed on a gold ring, it should not communicate a white stain. Ivory black is detected in it, by throwing a small portion on a red-hot iron, when a white matter (phosphate of lime) will be left behind. Adulteration by sulphuret of antimony is shown, if muriatic acid boiled on a portion of the powder, acquires the property of causing a precipitate of oxychloride of antimony when added to water. According to the views of Mr. Brande, ethiops mineral consists of one eq. of bisulphuret of mercury, mixed with about ten and a half eqs. of sulphur in excess.

Medical Properties and Uses. Ethiops mineral is supposed to be alterative, and as such is sometimes prescribed in glandular affections and cutaneous diseases. It has been given in scrofulous swellings, occurring in children; and from the mildness of its operation is considered well suited to such cases. The dose generally given is from five to thirty grains, repeated several times a day; but it has often been administered in much larger doses, without producing any obvious impression on the system. The late Dr. Duncan stated that he had given it in doses of several drachms for a considerable length of time, with scarcely any effect. B.

HYDRARGYRI SULPHURETUM RUBRUM. *U. S., Dub.*
HYDRARGYRI BISULPHURETUM. *Lond.* CINNABARIS. *Ed.* Red Sulphuret of Mercury. Bisulphuret of Mercury. Cinnabar.

“Take of Mercury *forty ounces*; Sulphur *eight ounces*. Mix the Mercury with the melted Sulphur over the fire; and, as soon as the mass begins to swell, remove the vessel from the fire, and cover it with considerable force, to prevent combustion; then rub the mass into powder, and sublime.” *U. S.*

The *London* and *Edinburgh Colleges* take *two pounds* of mercury and *five ounces* of sulphur, and treat them as in the *U. S.* process.

“Take of Purified Mercury *nineteen parts*; Sublimed Sulphur *three parts*. Mix the Mercury with the melted Sulphur; and if the mixture takes fire, extinguish the flame by covering the vessel. Reduce the mass to powder, and sublime it.” *Dub.*

Mercury and sulphur, when heated together, unite with great energy, and a product is obtained, which by sublimation becomes the red or bisulphuret of mercury. In order to render the combination more prompt, the sulphur is first melted; and the addition of the mercury should be made gradually, while the mixture is constantly stirred. Dr. Barker recommends the addition of the metal by straining it upon the melted sulphur through a linen cloth, whereby it falls in the form of a shower, in a minutely divided state. When the temperature has arrived at a certain point, the combination takes place suddenly with a slight explosion, and with the inflammation of the

sulphur, which must be extinguished by covering the vessel. A black mass will thus be formed, containing generally an excess of sulphur, which, before the sublimation is performed, should be got rid of by gently heating the matter reduced to powder on a sand-bath. The sublimation is best performed, on a small scale, in a loosely stopped glass matrass, which should be placed in a crucible containing sand, and, thus arranged, exposed to a red heat. The equivalent quantities for forming this sulphuret, are 32.2 of sulphur, and 202 of mercury.

Preparation on the Large Scale. Cinnabar is seldom or never prepared on a small scale, being made in large quantities for the purposes of the arts. In Holland, where it is principally manufactured, the sulphur is melted in a cast iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. In proportion as the quantity of the materials employed in one operation is greater, will the product have a finer tint. It is also important in the manufacture to use the materials pure, and to drive off any uncombined sulphur which may exist in the mass, before submitting it to sublimation.

Properties, &c. Red sulphuret of mercury is in the form of heavy, brilliant, crystalline masses, of a deep red colour and fibrous texture. It is inodorous and tasteless, and insoluble in water and alcohol. It is not acted on by nitric, muriatic, or cold sulphuric acid, nor by solutions of the caustic alkalies; but it is soluble in nitro-muriatic acid, on account of the chlorine which the mixed acid contains. When heated with potassa, it yields globules of mercury. In the open air it is decomposed by heat, the sulphur becoming sulphurous acid, and the mercury being volatilized. In close vessels, at a red heat, it sublimes without decomposition, and condenses in a mass composed of a multitude of small needles. When duly levigated, it furnishes a powder of a brilliant red colour, and in this state constitutes the paint called *vermilion*. It occurs native, and forms the principal ore of mercury, and that from which the metal is exclusively extracted. It should not be purchased in powder; as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, acetic acid, digested with it, will yield a yellow precipitate (iodide of lead) with iodide of potassium. Dragon's blood may be detected by alcohol, which will take up the colouring matter of this vegetable product, if present; and if chalk be mixed with it, effervescence will be excited on the addition of an acid. This sulphuret is composed of one eq. of mercury 202, and two of sulphur 32.2=234.2.

Medical Properties and Uses. Cinnabar was formerly considered to be alterative and anthelmintic, but is at present seldom or never given internally. It is sometimes employed in the way of fumigation, as a rapid sialagogue, in venereal ulcers of the nose and throat, in cases in which it is an object of importance to bring the system under the influence of the mineral in the shortest possible time. The dose for internal exhibition is from ten grains to half a drachm, in the form of electuary or bolus. When used by fumigation, half a drachm may be thrown on a red-hot iron, and the fumes inhaled as they arise. These consist of sulphurous acid gas and mercurial vapour, the former of which must prove highly irritating to the patient's lungs. A better substance for mercurial fumigation is the black oxide of mercury.

B.

HYDRARGYRUM AMMONIATUM. *U. S.* HYDRARGYRI AMMONIO-CHLORIDUM. *Lond.* Hydrargyri Precipitatum Album. *Ed.* HYDRARGYRI SUBMURIAS AMMONIATUM. *Dub.* Ammoniated Mercury. *White Precipitate.*

“Take of Corrosive Chloride of Mercury *six ounces*; Distilled Water *a gallon*; Solution of Ammonia *eight fluidounces*. Dissolve the Corrosive Chloride of Mercury in the Water, with the aid of heat, and to the solution, when cold, add the Solution of Ammonia, frequently stirring. Wash the precipitate till it becomes tasteless, and dry it.” *U. S.*

The *London* and *Edinburgh* processes are essentially the same as the above.

“Add to the liquor poured off from Precipitated Calomel, as much Water of Caustic Ammonia as may be sufficient completely to precipitate the metallic salt. Wash the precipitate with cold Distilled Water, and dry it on bibulous paper.” *Dub.*

All the Pharmacopœias now agree in obtaining white precipitate, by precipitating a solution of corrosive sublimate by ammonia. The Dublin process is not an exception; for the liquor poured off from precipitated calomel is in part a solution of corrosive sublimate. When ammonia, in slight excess, is added to a cold solution of corrosive sublimate, muriate of ammonia is formed in solution, and the white precipitate of the Pharmacopœias is thrown down, which, according to Dr. Kane, has a composition corresponding to one eq. of protochloride of mercury, united with one eq. of a compound represented by one eq. of ammonia, *minus* one eq. of hydrogen. To this compound, represented by NH_2 , Kane has given the name of *amidogen*, the *amide* of some other chemists. The reaction may be thus explained. Two eqs. of ammonia are decomposed into one eq. of ammonium (NH_4) and one eq. of amide (NH_2); and one eq. of corrosive sublimate is resolved into one eq. of chlorine and one eq. of calomel. The chlorine unites with the ammonium and remains in solution as chloride of ammonium (muriate of ammonia), and the calomel precipitates with the amide as white precipitate. In symbols the reaction is thus denoted; $2\text{NH}_3 + \text{HgCl}_2 = \text{NH}_4\text{Cl} + \text{HgCl} + \text{NH}_2$. For an explanation of what is meant by *ammonium*, see page 80. The analysis of Kane forms a virtual agreement with those of Guibourt and Hennell; for Guibourt's results, minus the elements of one eq. of water, and Hennell's, minus the elements of two eqs. of the same liquid, give exactly the constituents found by Kane.

Properties, &c. Ammoniated mercury is in powder or pulverulent masses, perfectly white, insoluble in water and alcohol, and having a taste, at first earthy and afterwards metallic. When heated with a solution of caustic potassa, it yields ammonia and becomes yellow. Exposed to heat it is decomposed, and resolved into nitrogen, ammonia, and protochloride of mercury or calomel. Adulteration with white lead, chalk, or sulphate of lime, may be detected by exposing a sample to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charry residuum will be obtained on the application of heat. Lead and starch may also be found by digesting the white precipitate with acetic acid, and testing the acetic solution with iodide of potassium, which, if lead be present, will give a yellow precipitate, and if starch, a blue one. The absence of protoxide of mercury is shown by its not being blackened when rubbed with lime-water.

Medical Properties and Uses. Ammoniated mercury is used only as an external application.

Off. Prep. Unguentum Hydrargyri Ammoniatum, *U. S.*, *Lond.*, *Ed.*, *Dub.*; Unguentum Sulphuris Compositum, *U. S.* B.

HYDRARGYRUM CUM CRETÂ. *U.S., Lond., Ed., Dub.*
Mercury with Chalk.

“Take of Mercury *three ounces*; Prepared Chalk *five ounces*. Rub them together till all the globules disappear.” *U.S., Lond., Ed.*

The *Dublin College* prepares it in the same manner as *Mercury with Magnesia*, only substituting precipitated carbonate of lime for carbonate of magnesia.

When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic lustre, and assumes the form of a blackish or dark gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens; and the mercury is said to be extinguished. It was formerly thought that the metal was oxidized in the process, and that the medical activity of the preparation depended on the presence of the black or protoxide of mercury. At present, the change is generally attributed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury, in which the metal is extinguished by trituration, a very small portion is converted into protoxide, while by far the greater part remains in the metallic state.

Mercury with chalk is a grayish powder, in which globules of mercury can generally be seen with the aid of a microscope; as the metal can scarcely be completely extinguished with chalk alone by any length of trituration. Mr. Jacob Bell found that by powerfully pressing it, a considerable quantity of metal was separated in the form of globules.* Mr. Phillips states that the extinguishment of the mercury is greatly accelerated by the addition of a little water. It is said that a precipitated oxide of mercury is sometimes added with a view to save time in the trituration. This addition is injurious; as, even though it may be in the state of protoxide, it is liable to be converted into the deutoxide of mercury, and thereby to render the preparation irritating to the stomach, in which it may even form corrosive sublimate with the muriatic acid often present in that organ. The mercury contained in this preparation is volatilized by heat. The remaining chalk is dissolved by dilute acetic acid, and the solution is not coloured by sulphuretted hydrogen. The presence of any probable metallic impurity may be detected in this way.

Medical Properties and Uses. Mercury with chalk is a very mild mercurial, similar in its properties to the blue pill, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children, attended with deficient biliary secretion, indicated by white or clay-coloured stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in diarrhœa. Eight grains of the preparation, according to the *U.S., London and Edinburgh Pharmacopœias*, contain three grains of mercury. The dose is from five grains to half a drachm twice a day. Two or three grains is the dose for a child. It should not be given in pill with substances which become hard on keeping; as the contraction of the mass presses out the mercury, which, in time, appears in globules in the interior of the pill. W.

* See a paper by Mr. Jacob Bell, in the *Pharmaceutical Transactions* for Nov. 1841, republished in the *American Journal of Pharmacy*, xiv. 239.

HYDRARGYRUM CUM MAGNESIÂ. *Dub.* *Mercury with Magnesia.*

“Take of Purified Mercury, Manna, each, *two parts*; Carbonate of Magnesia *one part*. Rub the Mercury with the Manna in an earthenware mortar, dropping in sufficient water to give to the mixture the consistence of syrup, and continue the trituration till the globules disappear. Then add, still rubbing, an eighth part of the Carbonate of Magnesia; and when this is well mixed with the other ingredients, add sixteen parts of hot water, and agitate the mixture. Let this stand for some time that the sediment may subside, and then decant the fluid. Repeat the washing twice, that the whole of the Manna may be removed; and with the sediment, while it is still moist, mix the remainder of the Carbonate of Magnesia. Lastly, dry the powder on bibulous paper.” *Dub.*

The use of the manna in this process is merely to facilitate the extinction of the mercury; as it is wholly washed away, and the metal is left mixed with magnesia. This preparation has the same virtues with the preceding, but may be preferably used in the complaints of children attended with constipation. W.

INFUSA.

Infusions.

These are aqueous solutions obtained by treating with water, without the aid of ebullition, vegetable products which are only partly soluble in that liquid. The water employed may be hot or cold according to the effects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance, and macerating in a lightly closed vessel till the liquid cools. The soluble principles are thus extracted more rapidly, and, as a general rule, in larger proportion than at a lower temperature. Some substances, moreover, are dissolved in this manner, which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable; and this may be effected by placing the vessel near the fire. Cold water is preferred, when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case; and, in warm weather, there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a very strong infusion is required, the *process by displacement* may be advantageously resorted to. (See pages 763 and 769.) The water employed should be free from saline impurities, which frequently produce precipitates, and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to that of pumps or springs.

The substance to be acted on should be sliced or bruised, or employed in the state of powder; but this last condition is seldom requisite, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases, it is sufficient to strain through fine linen or muslin. When, however, percolation or displacement is resorted to, the substance should be more or less finely powdered. Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Mr. Brande suggests the use of clean metallic vessels, which, when finely polished retain the heat for a

greater length of time; but they are also more liable to chemical alteration, and may sometimes injuriously affect the preparation.

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in families, and the propriety of their introduction into the Pharmacopœia has been doubted; but it is desirable to have certain fixed standards for the convenience of the medical practitioner; and it is sometimes convenient to direct infusions from the apothecary, for whose guidance officinal formulæ are necessary. Physicians would, indeed, find their advantage in more frequently directing them from the shops, instead of leaving their preparation to the carelessness or want of skill of the attendants upon the sick. For a mode of preserving infusions, the reader is referred to the introductory observations to the second part of this work, pages 765 and 766.

As we have already treated of the chemical relations and medical properties of the substances used in infusion, it would be useless repetition to enlarge upon these points in the following details. We shall touch upon them only in cases of peculiar interest, or where changes requiring particular notice may grow out of the nature of the process. W.

INFUSUM ANGUSTURÆ. *U. S., Dub.* INFUSUM CUSPARIÆ. *Lond., Ed.* *Infusion of Angustura Bark.*

“Take of Angustura Bark, bruised, *half an ounce*; Boiling water *a pint*. Macerate for two hours in a covered vessel, and strain.” *U. S.*

The *London College* directs *five drachms to a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, *five drachms to a pint* [Imp. meas.] of boiling water; the *Dublin*, *two drachms to half a pint* of boiling water; and all proceed as above.

The dose of the infusion is two fluidounces repeated every two, three, or four hours. W.

INFUSUM ANTHEMIDIS. *U. S., Lond., Ed.* INFUSUM CHAMÆMELI. *Dub.* *Infusion of Chamomile.*

“Take of Chamomile *half an ounce*; Boiling Water *a pint*. Macerate for ten minutes in a covered vessel, and strain.” *U. S.*

The *London College* orders *five drachms* of the flowers to a *pint* [Imperial measure] of boiling distilled water, and proceeds as above; the *Edinburgh*, *five drachms to a pint* [Imp. meas.] of boiling water, and infuses for twenty minutes. The *Dublin College* takes *two drachms* of the flowers and *half a pint* of boiling water, digests for twenty-four hours, and strains through linen.

The infusion of chamomile has the odour and taste of the flowers. It affords precipitates with gelatin, yellow Peruvian bark, sulphate of iron, tincture of chloride of iron, nitrate of silver, corrosive chloride of mercury, and the acetates of lead. (*London Dispensatory*.) As a tonic it is given cold in the dose of two fluidounces several times a day. To assist the operation of emetic medicines it should be administered in the tepid state, and in large draughts. The infusion prepared by maceration in cold water is more grateful to the palate and stomach than that made with boiling water, but is less efficient as an emetic. W.

INFUSUM ARMORACIÆ. *U. S.* INFUSUM ARMORACIÆ COMPOSITUM. *Lond., Dub.* *Infusion of Horse-radish.*

“Take of Horse-radish [fresh root], sliced, Mustard [seed], bruised, each, *an ounce*; Boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain.” *U. S.*

The *London College* macerates *an ounce* of the root and *an ounce* of the seeds in *a pint* [Imperial measure] of boiling distilled water, in a covered vessel, for two hours, and strains; then adds *a fluidounce* of compound spirit of horse-radish. The process of the *Dublin College* differs from that of the *London* only in employing a wine-pint of boiling water, and a digestion of six hours.

This infusion is rendered turbid by the deposition of vegetable albumen, and in warm weather speedily runs into the putrefactive fermentation. It affords precipitates with the infusion of galls and of Peruvian bark, with the alkaline carbonates, nitrate of silver, and corrosive chloride of mercury. (*London Dispensatory*.) It has the stimulant properties of its two active ingredients, and is occasionally used in paralytic, scorbutic, and dropsical affections attended with general debility. The dose is about two fluidounces three or four times a day. W.

INFUSUM AURANTII COMPOSITUM. *Lond., Dub.* INFUSUM AURANTII. *Ed.* *Compound Infusion of Orange Peel.*

"Take of dried Orange Peel *half an ounce*; fresh Lemon Peel *two drachms*; Cloves, bruised, *a drachm*; Boiling Distilled Water *a pint* [Imperial measure]. Macerate for a quarter of an hour, in a lightly covered vessel, and strain." *Lond.*

The *Edinburgh* process differs from the above only in the use of boiling water not distilled, and in straining through linen or calico. The *Dublin College* takes *two drachms* of dried orange peel, *a drachm* of fresh lemon peel, *half a drachm* of bruised cloves, and *half a pint* of boiling water; and digests for a quarter of an hour.

This infusion is given as a grateful stomachic in the dose of two or three fluidounces. W.

INFUSUM CARYOPHYLLI. *U. S., Lond., Ed.* INFUSUM CARYOPHYLLORUM. *Dub.* *Infusion of Cloves.*

"Take of Cloves, bruised, *two drachms*; Boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* takes *three drachms* of cloves, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, *three drachms* of cloves and *a pint* [Imp. meas.] of boiling water; the *Dublin*, *a drachm* of cloves, and *half a pint* of boiling water; and all proceed as above.

The infusion of cloves affords precipitates with lime-water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (*Phillips*.) The dose is about two fluidounces. W.

INFUSUM CASCARILLÆ. *U. S., Lond., Ed., Dub.* *Infusion of Cascarella.*

"Take of Cascarella, bruised, *an ounce*; Boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London College* directs *an ounce and a half* of bruised cascarella, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, the same quantities of the bark and of boiling water; the *Dublin*, *half an ounce* of the bark to *half a pint* of boiling water; and all proceed as above.

This infusion affords precipitates with lime-water, infusion of galls, nitrate of silver, acetate and subacetate of lead, sulphate of zinc, and sulphate of iron. (*London Dispensatory*.) The medium dose is two fluidounces.

Off. Prep. Mistura Cascarillæ Composita, *Lond.*

W.

INFUSUM CATECHU COMPOSITUM. *U. S., Lond., Dub.*INFUSUM CATECHU. *Ed. Compound Infusion of Catechu.*

"Take of Catechu, in powder, *half an ounce*; Cinnamon, bruised, *a drachm*; boiling Water *a pint*. Macerate for an hour in a covered vessel, and strain." *U. S.*

"Take of Extract of Catechu, in powder, *six drachms*; Cinnamon, bruised, *a drachm*; boiling Distilled Water *a pint* [Imperial measure]. Macerate for an hour in a lightly-covered vessel, and strain." *Lond.*

"Take of Catechu, in powder, *six drachms*; Cinnamon, in powder, *one drachm*; Syrup *three fluidounces*; boiling Water *seventeen fluidounces*. Infuse the Catechu and Cinnamon with the Water for two hours, strain through linen or calico, and add the Syrup." *Ed.*

"Take of Extract of Catechu *two drachms and a half*; Cinnamon, bruised, *half a drachm*; boiling Water *half a pint*. Digest for an hour in a covered vessel, and strain through linen." *Dub.*

This is an elegant mode of administering catechu. The dose is from one to three fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM CHIRETTÆ. *Ed. Infusion of Chiretta.*

"Take of Chiretta *four drachms*; boiling Water [Imperial measure] *one pint*. Infuse for two hours, and strain through linen or calico." *Ed.*

The dose of this simple bitter is from one to three fluidounces. W.

INFUSUM CINCHONÆ. *U. S., Lond., Ed., Dub. Infusion of Peruvian Bark.*

"Take of Peruvian Bark, bruised, *an ounce*; boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain.

"This infusion may also be prepared from the same quantity of Bark, in coarse powder, in the following manner:—Having moistened the Bark thoroughly with Water, introduce it into an apparatus for displacement, press it slightly, and pour Water upon its surface so as to keep it covered. So long as the liquid passes turbid, return it into the apparatus; then allow the filtration to continue until one pint of clear infusion is obtained." *U. S.*

"Take of Bark of the *Cinchona lancifolia* [pale bark], bruised, *an ounce*; boiling Distilled Water *a pint* [Imperial measure]. Macerate for six hours in a lightly-covered vessel, and strain." *Lond.*

"Take of any species of *Cinchona*, according to prescription, *one ounce* in powder; boiling Water *one pint* [Imp. measure]. Infuse for four hours in a covered vessel, and then strain through linen or calico." *Ed.*

"Take of Bark of the *Cinchona lancifolia*, in coarse powder, *an ounce*; cold Water *twelve fluidounces*. Triturate the Bark with a little of the Water, and add the remainder during the trituration. Macerate for twenty-four hours, with frequent agitation, and decant the clear liquor." *Dub.*

We can discover no good reason for the exclusive employment by the London and Dublin Colleges of the pale bark in the preparation of this infusion. The *U. S.* and *Edinburgh Pharmacopœias*, wisely, we think, leave the particular variety to the choice of the physician.

Though the infusion with boiling water is more quickly prepared than the cold infusion of the Dublin College, and therefore better adapted to cases of emergency, yet the latter is a more elegant preparation, not turbid like the former, and at least equally efficient. The trituration directed by the Dublin College facilitates the process, by thoroughly wetting the powder, and thus enabling it to be more readily diffused through the liquid.

We should prefer, however, the cold infusion prepared by percolation, as directed by the U. S. Pharmacopœia, supposing the process to be skilfully conducted. Perhaps it would be better, that the bark should be in moderately fine than in coarse powder.

The infusion of cinchona affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive chloride of mercury, arsenious acid, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, columbo, cascarilla, horse-radish, cloves, catechu, orange-peel, foxglove, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. (*London Dispensatory*.) Few, however, of these substances diminish the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. The same is said to be the case with tartaric and oxalic acids, and the soluble tartrates and oxalates. For an elaborate account of the effect of the infusions of the different varieties of Peruvian Bark on other substances, the reader is referred to a paper in the *Am. Journ. of Pharm.* ix. 128.

The infusion of cinchona may be advantageously administered in cases which require tonic treatment, but do not call for the full powers of the bark. The medium dose is two fluidounces to be repeated three or four times a day, or more frequently in acute diseases. W.

INFUSUM CINCHONÆ COMPOSITUM. U. S. *Compound Infusion of Peruvian Bark.*

“Take of Peruvian Bark, in powder, *an ounce*; Aromatic Sulphuric Acid *a fluidrachm*; Water *a pint*. Macerate for twelve hours, occasionally shaking, and strain.” U. S.

This is an elegant and very efficient preparation. Water extracts from bark the kinates of quinia and cinchonina, but leaves behind the compounds which these principles form with the cinchonic red. The ordinary infusion, therefore, is rather feeble. But the addition of the acid ensures the solution of all or nearly all the active matter. We have been long in the habit of using this infusion, and have had reason to be satisfied with its efficacy. The Yellow Calisaya or best red bark should be selected, when a strong preparation is desired. The bark might be more quickly and perhaps more thoroughly exhausted by the method of percolation, as directed in the simple infusion; but in this case care should be taken to employ a glass or porcelain percolator, and the acid should be added to the portion of water first employed to moisten the powder. The medium dose of the infusion is two fluidounces, equivalent to a drachm of the bark. W.

INFUSUM COLOMBÆ. U. S., *Dub.* INFUSUM CALUMBÆ. *Lond., Ed.* *Infusion of Columbo.*

“Take of Columbo, bruised, *half an ounce*; boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain.” U. S.

The *London College* directs *five drachms* of columbo to a *pint* [Imperial measure] of boiling distilled water; the *Dublin*, *two drachms* of columbo to *half a pint* of boiling water; and both proceed as above.

“Take of Calumba, in coarse powder, *half an ounce*; cold Water about a *pint* [Imperial measure]. Triturate the Calumba with a little of the Water, so as to moisten it thoroughly; put it into a percolator, and transmit cold Water till sixteen fluidounces of infusion be obtained.” *Ed.*

The infusion prepared with boiling water contains a portion of the starch

of the columbo, and very soon spoils. That made with cold water, whether by maceration, or by percolation as directed by the Edinburgh College, is destitute of starch and keeps better. The hot infusion, however, is a good preparation when wanted for immediate use. The infusion of columbo is not disturbed by the salts of iron, and may be conveniently administered in connexion with them. The dose is two fluidounces three or four times a day. W.

INFUSUM DIGITALIS. *U. S., Lond., Ed., Dub. Infusion of Foxglove.*

"Take of Foxglove [dried leaves] *a drachm*; boiling Water *half a pint*; Tincture of Cinnamon *a fluidounce*. Macerate the Foxglove with the Water for four hours in a covered vessel, and strain; then add the Tincture of Cinnamon." *U. S.*

The *London College* takes *a drachm* of the dried leaves, *a fluidounce* of spirit of cinnamon, and *a pint* [Imperial measure] of boiling distilled water; macerates the leaves in the water for four hours; and, having strained the liquor, adds the spirit. The *Dublin* process corresponds with that of the *U. S. Pharmacopœia*, except that *half a fluidounce* of the spirit of cinnamon is employed instead of *a fluidounce* of the tincture. The *Edinburgh College* takes *two drachms* of the leaves, *two fluidounces* of spirit of cinnamon, and *eighteen fluidounces* of boiling water; and, having macerated the leaves in the water for four hours, strains through linen or calico, and adds the spirit.

The *U. S.* infusion is essentially the same with that employed by Withering. It affords precipitates with the sulphate of iron, acetate of lead, and infusion of Peruvian bark. (*London Dispensatory.*) The dose is half a fluidounce, repeated twice a day under ordinary circumstances, every eight hours in urgent cases, until the system is affected. That of the *London* preparation must be twice as great, in consequence of the much smaller proportion of digitalis in the infusion as directed in the *Pharmacopœia* of 1836. W.

INFUSUM DIOSMÆ. *U. S., Lond.* INFUSUM BUCKU. *Ed.* INFUSUM BUCHU. *Dub. Infusion of Buchu.*

"Take of Buchu [leaves] *an ounce*; boiling Water *a pint*. Macerate for four hours in a covered vessel, and strain." *U. S.*

The *London College* takes *an ounce* of the leaves, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, the same quantities of the leaves and of boiling water; the *Dublin*, *half an ounce* of the leaves and *half a pint* of boiling water; and all proceed essentially as above.

This infusion has the odour and taste, and the medical virtues of the leaves; and affords a convenient mode of administering the medicine. The dose is one or two fluidounces. W.

INFUSUM EUPATORII. *U. S.* *Infusion of Thoroughwort.*

"Take of Thoroughwort [the dried herb] *an ounce*; boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain." *U. S.*

As a tonic, this infusion should be taken cold in the dose of two fluidounces three or four times a day, or more frequently; as an emetic and diaphoretic, in large tepid draughts. W.

INFUSUM GENTIANÆ COMPOSITUM. *U. S., Lond., Dub.* INFUSUM GENTIANÆ. *Ed. Compound Infusion of Gentian.*

"Take of Gentian, bruised, *half an ounce*; Orange Peel [dried peel of

the Seville orange] bruised, Coriander bruised, each, *a drachm*; Diluted Alcohol, *four fluidounces*; Water [cold] *twelve fluidounces*. First pour on the Alcohol, and, three hours afterwards, the Water; then macerate for twelve hours, and strain." *U. S.*

The above was copied from the *Edinburgh* formula, which differs only in having *four fluidounces* [Imperial measure] of proof-spirit (*Ed.*), and *sixteen fluidounces* [Imp. meas.] of cold water.

The *London College* takes of sliced gentian and dried orange peel, each, *two drachms*, of fresh lemon peel *four drachms*, of boiling distilled water *a pint* [Imperial measure]; the *Dublin* takes *a drachm* of each of the solid ingredients and *twelve fluidounces* of water; both macerate for an hour in a lightly covered vessel, and strain.

The *U. S.* and *Edinburgh* infusion differs materially from the *London* and *Dublin*. The former has much more gentian in proportion to the solvent than the latter, and is therefore a much stronger bitter; while, by the use of cold instead of boiling water, less of the inert mucilaginous matter is extracted. The use of the diluted alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very apt to spoil. The preparation, however, may be considered rather in the light of a very weak tincture than of an infusion, and should be used accordingly.

The dose of the infusion of the *U. S.* Pharmacopœia is a fluidounce, that of the preparation of the *London College* two or three fluidounces, to be repeated three or four times a day.

Off. Prep. Mistura Gentianæ Composita, *Lond.* W.

INFUSUM HUMULI. *U. S.* INFUSUM LUPULI. *Lond.* Infusion of Hops.

"Take of Hops *half an ounce*; boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Hops *six drachms*; boiling Distilled Water *a pint* [Imperial measure]. Macerate for four hours in a lightly covered vessel, and strain." *Lond.*

The dose of this infusion is one or two fluidounces. W.

INFUSUM KRAMERIÆ. *U. S.*, *Lond.* Infusion of Rhatany.

"Take of Rhatany, bruised, *an ounce*; Boiling Water *a pint*. Macerate for four hours in a covered vessel and strain." *U. S.*

"Take of Rhatany *an ounce*; Boiling Distilled Water *a pint* [Imp. meas.]. Macerate for four hours in a lightly covered vessel, and strain." *Lond.*

The infusion of rhatany would probably be more efficient, if prepared by the mode of percolation with cold water from the root in a state of moderately fine powder, as directed for Peruvian Bark. The dose of the infusion is one or two fluidounces. W.

INFUSUM LINI. *U. S.*, *Ed.* INFUSUM LINI COMPOSITUM. *Lond.*, *Dub.* Infusion of Flaxseed.

"Take of Flaxseed *half an ounce*; Liquorice Root, bruised, *two drachms*; boiling Water *a pint*. Macerate for four hours in a covered vessel, and strain." *Lond.*

The *London College* directs *six drachms* of bruised flaxseed, *two drachms* of sliced liquorice root, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, the same except boiling water for boiling distilled water; the *Dublin*, *an ounce* of flaxseed, *half an ounce* of liquo-

rice root, and *two pints* of boiling water; all complete the process in the manner directed in the U. S. Pharmacopœia, except that the London and Edinburgh Colleges direct the maceration to take place near the fire.

This is a useful demulcent drink in inflammatory affections of the mucous membrane of the lungs and urinary passages. It may be taken *ad libitum*.
W.

INFUSUM MENTHÆ SIMPLEX. *Dub. Simple Infusion of Mint.*

“Take of the Dried Leaves of Spearmint *two drachms*; boiling Water sufficient to afford *six ounces* [fluidounces] of strained liquor.” *Dub.*

This is common mint tea, and may be taken *ad libitum*.

INFUSUM MENTHÆ COMPOSITUM. *Dub. Compound Infusion of Mint.*

“Take of the Dried Leaves of Spearmint *two drachms*; boiling Water sufficient to afford *six ounces* [fluidounces] of strained liquor. Digest for half an hour in a covered vessel, and strain the liquor when cold; then add, of Refined Sugar *two drachms*, Oil of Spearmint *three drops* dissolved in *half an ounce* [fluidounce] of Compound Tincture of Cardamom.” *Dub.*

This is an agreeable aromatic infusion, useful in allaying nausea and vomiting, and affording an eligible vehicle for unpleasant medicines. The dose is one or two fluidounces frequently repeated.
W.

INFUSUM PAREIRÆ. *Lond., Ed. Infusion of Pareira Brava.*

“Take of Pareira Brava *six drachms*; boiling Distilled Water *a pint* [Imperial measure]. Macerate for two hours, in a lightly covered vessel, and strain.” *Lond.*

The *Edinburgh* process differs only in having boiling water instead of boiling distilled water.

The infusion of pareira brava is highly esteemed by some English practitioners as a remedy in irritation and chronic inflammation of the urinary passages, and has been found useful in catarrh of the bladder. The dose is one or two fluidounces. Brodie employed a *decoction* of the root, which he prepared by boiling half an ounce in three pints of water down to a pint, and gave in the quantity of from eight to twelve fluidounces daily.
W.

INFUSUM PRUNI VIRGINIANÆ. *U.S. Infusion of Wild-cherry Bark.*

“Take of Wild-cherry Bark, bruised, *half an ounce*; Water [cold] *a pint*. Macerate for twenty-four hours, and strain.” *U.S.*

This is a peculiarly suitable object for officinal direction, as, in consequence of the volatile nature of one of its active ingredients, and for another reason before stated (see page 577), it is better prepared with cold water than in the ordinary mode. The period of maceration might with propriety be extended to twenty-four hours, or even longer in cold weather. The infusion of wild-cherry bark is one of the preparations to which the process of percolation or displacement is well adapted. (See pages 763 and 769.) When properly made, it is beautifully transparent, has the colour of Madeira wine, and the agreeable bitterness and peculiar flavour of the bark. The dose is two or three fluidounces three or four times a day, or more frequently when a strong impression is required.
W.

INFUSUM QUASSIÆ. *U.S., Lond., Ed., Dub.* Infusion of Quassia.

"Take of Quassia, rasped, *two drachms*; Water [cold] *a pint*. Macerate for twelve hours, and strain." *U. S.*

The *London College* takes *two scruples* of quassia sliced, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, *a drachm* of quassia in chips, and *a pint* [Imp. meas.] of boiling water; the *Dublin*, *a scruple* of quassia, and *half a pint* of boiling water; all macerate for two hours.

The proportion of quassia directed in the British Pharmacopœias is much too small. The London infusion contains the strength of only two grains of quassia in a fluidounce, the Dublin two grains and a half, and the Edinburgh three grains; while the dose of quassia in substance is from twenty grains to a drachm, and of the extract not less than five grains. We, therefore, prefer the proportions directed by our national Pharmacopœia. Boiling water may be employed when it is desirable to obtain the preparation quickly; but cold water affords a clearer infusion. The dose is two fluidounces three or four times a day. W.

INFUSUM RHEI. *U.S., Lond., Ed., Dub.* Infusion of Rhubarb.

"Take of Rhubarb, bruised, *a drachm*; boiling Water *half a pint*. Digest for two hours in a covered vessel, and strain." *U. S., Dub.*

"Take of Rhubarb, sliced, *three drachms*; boiling Distilled Water, *a pint* [Imperial measure]. Macerate for two hours, in a lightly covered vessel, and strain." *Lond.*

"Take of Rhubarb, bruised into coarse powder, *one ounce*; Spirit of Cinnamon *two fluidounces*; boiling Water *eighteen fluidounces*. Infuse the Rhubarb for twelve hours, in the Water, in a covered vessel, add the Spirit, and strain through linen or calico." *Ed.*

In order that the rhubarb may be exhausted, it should be digested with the water near the fire at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel-seed, or nutmeg, which improves the taste of the infusion, and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connexion with the rhubarb.

This infusion may be given as a gentle laxative, in the dose of one or two fluidounces, every three or four hours, till it operates. It is occasionally used as a vehicle of tonic, antacid, or more active cathartic medicines. The stronger acids, and most metallic solutions, are incompatible with it. W.

INFUSUM ROSÆ COMPOSITUM. *U.S., Lond.* INFUSUM ROSÆ. *Ed.* INFUSUM ROSÆ ACIDUM. *Dub.* Compound Infusion of Roses.

"Take of Red Roses [dried petals] *half an ounce*; boiling Water, *two pints and a half*; Diluted Sulphuric Acid *three fluidrachms*; Sugar [refined] *an ounce and a half*. Pour the Water upon the Roses in a glass vessel; then add the Acid, and macerate for half an hour; lastly, strain the liquor, and add the Sugar." *U. S.*

The *London College* takes *three drachms* of dried red roses, *a fluidrachm and a half* of diluted sulphuric acid, *six drachms* of sugar, and *a pint* [Imperial measure] of boiling distilled water, and proceeds as above, except that it macerates for six hours instead of half an hour. The *Edinburgh* process corresponds with the London, except that boiling water is used

instead of boiling distilled water, the maceration continues only for an hour, and the acid is added after the maceration instead of before it. The *Dublin* process corresponds with that of the U. S. Pharmacopœia, except that the petals are directed without their claws, and *three pints* of water are employed instead of two pints and a half.

The red roses serve little other purpose than to impart a fine red colour and a slight astringent flavour to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. It is refrigerant and astringent, and affords a useful and not unpleasant drink in hemorrhages and colliquative sweats. It is much used by British practitioners as a vehicle for saline medicines, particularly sulphate of magnesia, the taste of which it serves to cover. It is also employed as a gargle, usually in connexion with acids, nitre, alum, or tincture of Cayenne pepper. The dose is from two to four fluidounces.

W.

INFUSUM SARSAPARILLÆ. U. S. INFUSUM SARSAPARILLÆ COMPOSITUM. *Dub.* *Infusion of Sarsaparilla.*

"Take of Sarsaparilla, bruised, *an ounce*; Boiling Water, *a pint*. Digest for two hours in a covered vessel, and strain.

"This infusion may also be prepared by the process of displacement, in the manner directed for Infusion of Peruvian Bark." U. S. (See *Infusum Cinchonæ*.)

"Take of Sarsaparilla Root, previously cleansed with cold water and sliced, *an ounce*; Lime-water *a pint*. Macerate for twelve hours in a covered vessel, with occasional agitation, and strain." *Dub.*

From the experiments of Soubeiran it appears that, by maceration in cold water for twenty-four hours, the active principle of sarsaparilla is extracted as effectually as by infusion in boiling water and digestion for two hours, and that in either case the infusion is stronger than the decoction; but the aqueous preparation which he found to possess most of the sensible properties of the root, was made by infusing the spirituous extract in water. (See page 951.) In all his experiments, M. Soubeiran employed the same proportions of the root and of water. (*Journ. de Pharm.* xvi. 43.) These observations correspond with those long since made by Hancock, and recently confirmed by Mr. T. J. Husband, of this city, so far as relates to the greater solvent power of spirit than of water over sarsaparilla. (*Am. Journ. of Pharm.* xv. 6.) Water does not appear competent completely to exhaust sarsaparilla of its active principle unless employed in very large proportion. Still the watery preparations made from the root are certainly not without efficacy; and the inference from the experiments of Soubeiran is, that it is of little consequence whether the infusion be made with hot or cold water, supposing time to be allowed in the latter case. It is probable that percolation, as directed by the U. S. Pharmacopœia in the second formula above given, will be found the most efficacious plan. The sarsaparilla should in this case be reduced to powder. No advantage can result from the use of lime-water as directed by the Dublin College. From two to four fluidounces of the infusion may be taken three times a day.

W.

INFUSUM SCOPARII. *Lond.* *Infusion of Broom.*

"Take of Broom *an ounce*; boiling Distilled Water *a pint* [Imperial measure]. Macerate for four hours, in a lightly covered vessel, and strain." *Lond.*

Used occasionally as a diuretic and aperient in dropsy. The dose is from one to four fluidounces.

W.

INFUSUM SENEGÆ. *Ed. Infusion of Seneka.*

“Take of Senega *ten drachms*; boiling Water *one pint* [Imperial measure]. Infuse for four hours in a covered vessel, and strain.”

The efficacy of the officinal decoction of seneka has been proved by so long an experience, that we should be cautious in allowing it to be superseded by the infusion on hypothetical grounds alone. The dose of the preparation is from *one to three fluidounces*. W.

INFUSUM SENNÆ. *U. S., Ed. INFUSUM SENNÆ COMPOSITUM. Lond., Dub. Infusion of Senna.*

“Take of Senna *an ounce*; Coriander, bruised, *a drachm*; boiling Water *a pint*. Macerate for an hour in a covered vessel, and strain.” *U. S.*

The *London College* orders *fifteen drachms* of senna, *four scruples* of sliced ginger, and *a pint* [Imperial measure] of boiling distilled water; the *Edinburgh*, *an ounce and a half* of senna, *four scruples* of ginger, and *a pint* [Imp. meas.] of boiling water; and the *Dublin*, *an ounce* of senna, *a drachm* of ginger, and *a pint* of boiling water; all macerate as above directed.

We decidedly prefer the formula of the *U. S. Pharmacopœia*. The proportions of senna directed by the *London* and *Edinburgh Colleges* are unnecessarily large; and coriander is a better addition than ginger to an infusion very often given in inflammatory affections. This infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to connect with it manna and some one of the neutral salts, which both increase its efficacy and render it less painful in its operation. The following is a good formula for the preparation of senna tea. Take of senna *half an ounce*; sulphate of magnesia, manna, each, *an ounce*; fennel seed *a drachm*; boiling water *half a pint*. Macerate in a covered vessel till the liquid cools. One-third may be given for a dose, and repeated every four or five hours till it operates. The dose of the infusion of the *U. S. Pharmacopœia* is about four fluidounces.

Off. Prep. Mistura Gentianæ Composita, *Lond.*

W.

INFUSUM SENNÆ CUM TAMARINDIS. *Dub. INFUSUM SENNÆ COMPOSITUM. Ed. Infusion of Senna with Tamarinds.*

“Take of Senna *one drachm*; Tamarinds *one ounce*; Coriander, bruised, *one drachm*; Muscovado [sugar] *half an ounce*; boiling Water *eight fluidounces*. Infuse for four hours, with occasional stirring in a covered vessel, not glazed with lead, and then strain through linen or calico.

“This infusion may be likewise made with twice or thrice the prescribed quantity of senna.” *Ed.*

The process of the *Dublin College* corresponds closely with the above, but does not admit the triple quantity of senna. In this infusion the unpleasant taste of the senna is covered by the acidity of the tamarinds and sweetness of the sugar. It is aperient and refrigerant, and is well adapted to febrile complaints when a laxative operation is desired. The dose is from two to four fluidounces. W.

INFUSUM SERPENTARIÆ. *U. S., Lond., Ed. Infusion of Virginia Snakeroot.*

“Take of Virginia Snakeroot *half an ounce*; boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain.” *U. S.*

The *London College* employs *half an ounce* of the root with *a pint* [Imperial measure] of boiling distilled water, and macerates for four hours. The *Edinburgh* process differs from the *London* only in the use of boiling water instead of boiling distilled water.

This is the ordinary form in which serpentaria is employed. The dose is one or two fluidounces, repeated every two hours in low forms of fever, but less frequently in chronic affections. W.

INFUSUM SIMARUBÆ. *Lond., Ed., Dub. Infusion of Simaruba.*

"Take of Simaruba [bark], bruised, *three drachms*; boiling Distilled Water *a pint* [Imperial measure]. Macerate for two hours in a lightly covered vessel, and strain." *Lond.*

The *Edinburgh* process differs only in the use of boiling water instead of boiling distilled water.

The *Dublin College* takes *half a drachm* of the bark, and *half a pint* of boiling water, and proceeds as above.

This preparation is little used in the United States. The dose is two fluidounces. W.

INFUSUM SPIGELIÆ. *U.S. Infusion of Pinkroot.*

"Take of Pinkroot *half an ounce*; boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain." *U.S.*

The dose of this infusion, for a child two or three years old, is from four fluidrachms to a fluidounce; for an adult, from four to eight fluidounces, repeated morning and evening. A quantity of senna equal to that of the spigelia is usually added in order to insure a cathartic effect. W.

INFUSUM TABACI. *U.S., Dub. ENEMA TABACI. Lond., Ed. Infusion of Tobacco.*

"Take of Tobacco *a drachm*; boiling Water *a pint*. Macerate for an hour in a covered vessel, and strain." *U.S., Dub.*

The *London College* takes *a drachm* of tobacco, and *a pint* [Imperial measure] of boiling distilled water, macerates for an hour, and strains. The *Edinburgh College* takes from *fifteen to thirty grains* of tobacco, and *eight fluidounces* of boiling water, infuses for half an hour, and strains.

This is used only in the form of enema in strangulated hernia, obstinate colic, and retention of urine from spasm of the urethra. Only half of the pint should be employed at once; and if this should not produce relaxation in half an hour, the remainder may be injected. Fatal consequences have resulted from too free a use of tobacco in this way. W.

INFUSUM ULMI. *U.S. Infusion of Slippery Elm Bark.*

"Take of Slippery Elm Bark, sliced and bruised, *an ounce*; boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain." *U.S.*

This infusion may be used *ad libitum* as a demulcent and nutritious drink in catarrhal and nephritic diseases, and in inflammatory affections of the intestinal mucous membrane. W.

INFUSUM VALERIANÆ. *U.S., Lond., Dub. Infusion of Valerian.*

Take of Valerian *half an ounce*; boiling Water *a pint*. Macerate for an hour in a covered vessel, and strain." *U.S.*

The *London College* takes *half an ounce* of valerian, and *a pint* [Imperial measure] of boiling distilled water, macerates for half an hour in a lightly covered vessel, and strains. The *Dublin College* directs *two drachms* of valerian, in coarse powder, *seven fluidounces* of boiling water, digestion for an hour, and straining after the liquid has become cold.

The dose of this infusion is two fluidounces, repeated three or four times a day, or more frequently. W.

IODINUM.

Preparation of Iodine.

LIQUOR IODINI COMPOSITUS. U.S. IODINEI LIQUOR COMPOSITUS. *Ed.* LIQUOR POTASSII IODIDI COMPOSITUS. *Lond.* *Compound Solution of Iodine.*

“Take of Iodine *six drachms*; Iodide of Potassium *an ounce and a half*; Distilled Water *a pint*. Dissolve the Iodine and Iodide of Potassium in the Water.” *U. S.*

“Take of Iodine *two drachms*; Iodide of Potassium *an ounce*; Distilled Water *sixteen fluidounces* [Imperial measure]. Dissolve the Iodide and Iodine in the Water with gentle heat and agitation.” *Ed.*

“Take of Iodide of Potassium *ten grains*; Iodine *five grains*; Distilled Water *a pint* [Imperial measure]. Mix that they may dissolve.” *Lond.*

Although these preparations are all aqueous solutions of iodine and iodide of potassium, yet they differ very much in strength. Iodine is but sparingly soluble in water, but readily dissolves when associated with twice its weight of iodide of potassium. The U. S. solution corresponds in strength with Lugol's *concentrated* solution of iodine in iodide of potassium, and is intended to facilitate the administration of the combination in drops. The Edinburgh preparation is a weaker form of the same concentrated solution, in which the iodide of potassium is taken at a quantity four times the amount of the iodine, instead of twice its amount, the usual proportion adopted. Assuming 16 Imperial fluidounces to be the same as the wine pint, and it is only 5 fluidrachms less, then it will be found, on comparing the formulæ, that the Edinburgh solution is one-third as strong in iodine, and two thirds as strong in iodide of potassium as that of the U. S. Pharmacopœia. The London preparation is a *weak* solution, and is just twice as strong as Lugol's ioduretted mineral water of *medium* strength, assuming the Imperial fluidounce to be the same as the French ounce. The medicinal properties of these solutions depend mainly on the free iodine present in them, by which their dose must be regulated, and not by the iodide of potassium. The dose of the U. S. solution is six drops, containing about a quarter of a grain of iodine, twice a day, given in four tablespoonfuls of sweetened water, and gradually increased. For children, the dose is proportionably less. (See page 394). The Edinburgh solution may be given in doses about three times as large. The London preparation may be viewed as the foregoing solutions, brought nearly to the proper degree of dilution for exhibition. The dose is a fluidounce, containing a quarter of a grain of iodine, diluted with an equal bulk of water, and gradually increased to two fluidounces or more.

B.

LINIMENTA.

Liniments.

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand. They are usually thicker than water, but thinner than the ointments; and are always liquid at the temperature of the body.

W.

LINIMENTUM AMMONIÆ. U. S., Lond., Ed., Dub. *Liniment of Ammonia. Volatile Liniment.*

"Take of Solution of Ammonia *a fluidounce*; Olive Oil *two fluidounces*. Mix them." *U. S.*

The London and Edinburgh processes agree with the above. The *Dublin College* directs *two fluidrachms* of "Water of Caustic Ammonia" and *two fluidounces* of the oil.

The U. S., London, and Edinburgh Pharmacopœias, having adopted a solution of ammonia of the same strength, accord at present in the proportion of the solution and of oil employed in the liniment. In this preparation, the ammonia unites with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, frequently employed in inflammatory affections of the throat, catarrhal and other pectoral complaints of children, and in rheumatic pains. It is applied by rubbing it gently upon the skin, or placing a piece of flannel saturated with it over the affected part. Should it occasion too much inflammation, as sometimes happens, it must be diluted with oil.

W.

LINIMENTUM AMONIÆ COMPOSITUM. Ed. *Compound Liniment of Ammonia.*

"Take of Stronger Aqua Ammonia (D. 0.880) [Stronger Solution of Ammonia] *five fluidounces*; Tincture of Camphor *two fluidounces*; Spirit of Rosemary *one fluidounce*. Mix them well together. This liniment may be also made weaker for some purposes with *three fluidounces* of Tincture of Camphor and *two* of Spirit of Rosemary." *Ed.*

The compound liniment of ammonia is a very close imitation of Dr. Granville's *counter-irritant lotion*. Like that, it is of two strengths; the stronger containing five-eighths of its bulk of the ammoniacal solution, the weaker only one-half. They are nothing more than dilutions in different degrees of the officinal *Liquor Ammonia Fortior*, which is itself too powerful for convenient use. The tincture of camphor and spirit of rosemary can scarcely exercise, in this case, any peculiar therapeutical influence. These preparations are employed as prompt and powerful rubefacients, vesicatories, or escharotics, in various neuralgic, gouty, rheumatic, spasmodic, and inflammatory affections, in which strong and speedy counter-irritation is indicated. When mere rubefaction is desired, the weaker lotion may be used; and even for blistering or cauterizing, unless a very prompt effect is necessary. In the latter case the stronger lotion should be resorted to. They are applied by means of linen folded several times, or a thick piece of flannel saturated with the liniment. A convenient mode is to fill the wooden cover of a large pill or ointment box, an inch or two in diameter, with patent lint, saturate this with the liquid, and press it upon the part. The ammonia is thus prevented from escaping, and a definite boundary given to the inflammation. The application will generally produce rubefaction in a length of time varying from one to six or eight minutes, vesication in from three to ten minutes, and a caustic effect in a somewhat longer period.

W.

LINIMENTUM AMMONIÆ SESQUICARBONATIS. Lond. *Liniment of Sesquicarbonate of Ammonia.*

"Take of Solution of Sesquicarbonate of Ammonia *a fluidounce*; Olive Oil *three fluidounces*. Shake them together until they unite." *Lond.*

In this, as in the liniment of ammonia, a kind of fluid soap is formed; but the union between the oil and alkali is less perfect, and after a short time the soapy matter separates from the water. The preparation is therefore less elegant; and, as the end which it was probably intended to answer of affording a milder rubefacient, may be obtained by diluting the liniment of ammonia with olive oil, there seems to be no good reason for retaining it. W.

LINIMENTUM CALCIS. *U. S., Ed., Dub. Liniment of Lime.*

"Take of Lime-water, Flaxseed Oil, each, a *fluidounce*. Mix them." *U. S.*

The *Edinburgh College* directs equal measures of the same ingredients; the *Dublin*, three *fluidounces* of lime-water, and three of olive oil.

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the *Dublin College*, is often substituted for that of flaxseed; but possesses no other advantage than that of having a less unpleasant odour. This is a very useful liniment in recent burns and scalds. It is sometimes called *Carron oil*, from having been much employed at the iron works of that name in Scotland. W.

LINIMENTUM CAMPHORÆ. *U. S., Lond., Ed. OLEUM CAMPHORATUM. Dub. Camphor Liniment.*

"Take of Camphor half an ounce; Olive Oil two *fluidounces*. Dissolve the Camphor in the Oil." *U. S.*

The *London* and *Edinburgh Colleges* direct an ounce of camphor, and four *fluidounces* of olive oil; the *Dublin College*, a drachm of the former and an ounce of the latter.

This is employed as an anodyne embrocation in sprains, bruises, rheumatic or gouty affections of the joints, and other local pains. It is also supposed to have a discutient effect when rubbed upon glandular swellings.

LINIMENTUM CAMPHORÆ COMPOSITUM. *Lond., Dub. Compound Camphor Liniment.*

"Take of Camphor two ounces and a half; Solution of Ammonia seven *fluidounces* and a half; Spirit of Lavender a pint [Imperial measure]. Mix the solution of Ammonia with the Spirit; then, from a glass retort, with a slow fire, distil a pint; lastly, dissolve the Camphor in the distilled liquor." *Lond.*

The *Dublin College* takes two ounces of camphor, six *fluidounces* of solution of ammonia, and a pint of spirit of lavender; and proceeds in the same manner.

This preparation deserves a place rather among the Spirits or Tinctures than the Liniments. It may be imitated by dissolving a little oil of lavender in tincture of camphor, and adding spirit of ammonia. It is used as a rubefacient and at the same time anodyne embrocation, in local pains, particularly of a rheumatic character. W.

LINIMENTUM CANTHARIDIS. *U. S. Liniment of Spanish Flies.*

"Take of Spanish Flies, in powder, an ounce; Oil of Turpentine half a pint. Digest for three hours by means of a water-bath, and strain." *U. S.*

Oil of turpentine is an excellent solvent of the active principle of cantharides, and, when impregnated with it, acquires in addition to its own rubefacient properties those of a powerful epispastic. This liniment was

introduced into notice by Dr. Joseph Hartshorne, of Philadelphia, who employed it with great advantage as an external stimulant in the prostrate states of typhus fever. Caution, however, is necessary in its use, both to graduate its strength to the circumstances of the case, and not to apply it very extensively, lest it may produce severe and troublesome, if not dangerous vesication. (See *Eclectic Repertory*, vol. i. p. 94.) If too powerful in its undiluted state, it may be weakened by the addition of olive or linseed oil.

W.

LINIMENTUM HYDRARGYRI COMPOSITUM. *Lond.*
Compound Liniment of Mercury.

“Take of Stronger Mercurial Ointment, Lard, each, *four ounces*; Camphor *an ounce*; Rectified Spirit *a fluidrachm*; Solution of Ammonia *four fluidounces*. Rub the Camphor first with the Spirit, then with the Lard and Mercurial Ointment; lastly, add gradually the Solution of Ammonia, and mix the whole.” *Lond.*

This is a stimulating liniment, employed for the discussion of chronic glandular enlargements, swellings of the joints, and venereal tumours, and to promote the absorption of collections of fluid. It is said to be more apt to salivate than mercurial ointment. One drachm of it is to be rubbed upon the affected part night and morning.

W.

LINIMENTUM OPII. *Lond., Ed.* **LINIMENTUM SAPONIS CUM OPIO** *vel* **LINIMENTUM ANODYNUM.** *Dub.* *Liniment of Opium.*
Anodyne Liniment.

“Take of Castile Soap *six ounces*; Opium *an ounce and a half*; Camphor *three ounces*; Oil of Rosemary *six fluidrachms*; Rectified Spirit *two pints* [Imperial measure]. Macerate the Soap and Opium in the Spirit for three days; filter, add the Oil and Camphor, and agitate briskly.” *Ed.*

The *London* and *Dublin Colleges* merely mix their liniment of soap (*Tinctura Saponis Camphorata*) with tincture of opium; the former, in the proportion of *six* measures of the liniment to *two* of the tincture; the latter, of *four* parts to *three*.

This is commonly known by the name of *anodyne liniment*, and is employed as an anodyne and gently rubefacient embrocation in sprains, bruises, and rheumatic and gouty pains. It differs from the *camphorated tincture of soap* only in containing opium, and is most conveniently prepared by extemporaneously mixing that tincture with laudanum, as directed by the *London* and *Dublin Colleges*.

W.

LINIMENTUM SAPONIS CAMPHORATUM. *U.S.* *Camphorated Soap Liniment.* *Opodeldoc.*

“Take of Common Soap *three ounces*; Camphor *an ounce*; Oil of Rosemary, Oil of Origanum, each *a fluidrachm*; Alcohol *a pint*. Digest the Soap with the Alcohol, by means of a sand-bath, till it is dissolved; then add the Camphor and Oils, and when they are dissolved, pour the liquor into broad mouthed bottles. This Liniment has, when cold, the consistence of a soft ointment.” *U.S.*

This preparation is directed only by the *U.S. Pharmacopœia*. It differs from the common soap liniment (*Tinctura Saponis Camphorata*) chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made with olive oil. The former is peculiarly adapted to the purposes of this formula, in consequence of assuming, when its alcoholic solution cools, the consistence characteristic of the liniment. It is customary, after the solution of the soap has been effected, to pour the

liquor into small wide-mouthed glass bottles, containing about four fluid-ounces, in which it solidifies into a soft, semitransparent, uniform, yellowish-white mass. This liniment melts with the heat of the body, and therefore becomes liquid when rubbed upon the skin. It is much used, under the common name of *opodeldoc*, as an anodyne application in sprains, bruises, and rheumatic pains. W.

LINIMENTUM SIMPLEX. *Ed. Simple Liniment.*

“Take of Olive Oil *four parts*; White Wax *one part*. Dissolve the Wax in the Oil with a gentle heat, and agitate well as the fused mass cools and concretes.” *Ed.*

This is little employed. It may be used for keeping the skin soft and smooth in cold weather.

Off. Prep. Unguentum Zinci, *Ed.* W.

LINIMENTUM TEREBINTHINÆ. *U.S., Lond., Dub. LINIMENTUM TEREBINTHINATUM.* *Ed. Liniment of Turpentine.*

“Take of Oil of Turpentine *half a pint*; Resin Cerate *a pound*. Add the Oil of Turpentine to the Cerate previously melted, and mix them.” *U.S., Dub.*

“Take of Soft Soap *two ounces*; Camphor *an ounce*; Oil of Turpentine *sixteen fluidounces*. Shake them together until they are mixed.” *Lond.*

“Take of Resinous Ointment *four ounces*; Oil of Turpentine *five fluidounces*; Camphor *half an ounce*. Melt the ointment, and gradually mix with it the Camphor and Oil, till a uniform liniment be obtained.” *Ed.*

This preparation, made according to the U. S. and Dublin formulæ, is the liniment originally proposed by Dr. Kentish, and subsequently so highly lauded as a remedy in burns and scalds. It should be applied as soon after the occurrence of the accident as possible, and should be discontinued when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burned or scalded surface with pledgets of patent lint saturated with the liniment. It should not be allowed to come in contact with the sound parts. This liniment may also be successfully applied in other cases of cutaneous inflammation requiring stimulation, as in certain conditions of erysipelas. The liniment of the London College, which has been substituted, in the last edition of their Pharmacopœia, for the mixture of resin cerate and oil of turpentine, directed in the former edition, is a stimulating mixture, applicable wherever a powerful rubefacient impression is desired. W.

MAGNESIA.

Preparations of Magnesia.

MAGNESIA. *U.S., Lond., Ed., Dub. Magnesia.*

“Take of Carbonate of Magnesia *any quantity*. Put it into an earthen vessel, and expose it to a red heat for two hours, or till the carbonic acid is wholly expelled.” *U.S.*

“Take of Carbonate of Magnesia *four ounces*. Burn it for two hours in a strong fire.” *Lond.*

“Take any *convenient quantity* of Carbonate of Magnesia, expose it in a crucible to a full red heat for two hours, or till the powder, when suspended in water, presents no effervescence on the addition of muriatic acid. Preserve the product in well-closed bottles.” *Ed.*

“Take of Carbonate of Magnesia *any quantity*. Put it into a crucible, and subject it to a strong heat for two hours. When the Magnesia has become cool, preserve it in a glass vessel.” *Dub.*

By exposure to a red heat, the water and carbonic acid of the carbonate of magnesia are expelled, and the earth is obtained pure. According to Dr. Black, the carbonate loses seven-twelfths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent. of which from 15 to 20 per cent. is water. About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbonic acid. (*Duncan.*) A more certain indication, however, is the absence of effervescence when muriatic acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbonic acid, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to ensure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible; and, as in consequence of its levity it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk. The magnesia may thus be obtained of greater density; but this is an equivocal recommendation; and the French pharmaceutical writers direct that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression. The officinal direction, to keep the magnesia, after it has been prepared, in well-stopped glass vessels, is founded on the fact that it absorbs carbonic acid and water from the air; but the absorption goes on slowly, and the caution is often neglected in the shops. Its great bulk renders its introduction into small bottles inconvenient. A four ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration; and four times the quantity may be thus got into the same space. (*Journ. of the Phil. Col. of Pharm.* iii. 198.) The density of *Henry's magnesia*, which is at least four times that of the earth prepared in the ordinary way, has been ascribed to this cause. It has also been attributed to the influence of intense heat employed in the calcination; and both causes may contribute to it. The conjecture has even been advanced, that this magnesia, which has enjoyed so great a popularity in England and this country, is prepared by precipitating a solution of sulphate of magnesia by caustic potassa, as the earth afforded by this plan is comparatively dense. It is difficult to find any reasonable ground for the preference given to *Henry's magnesia*. If its density be owing to the employment of an intense heat in the calcination, it is rather an objection than otherwise, as its solubility in acids is thus diminished. In France the earth is esteemed in proportion to its levity. It is asserted that the magnesia, prepared from the carbonate procured by precipitating the sulphate of magnesia with carbonate of soda, is softer to the touch, and bears a closer resemblance to *Henry's* than that prepared from the ordinary carbonate. The fact is explained by the presence in common magnesia of a little sulphate of potassa, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica which originally existed in the carbonate of potassa employed to decompose the sulphate of magnesia, and of which the carbonate of soda is destitute.

Properties, &c. Pure magnesia is in the state of a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2·3. It was deemed infusible, till melted by means of the compound blowpipe of Dr. Hare. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature. It is almost insoluble, requiring, according to Dr. Fyfe, 5142 parts of water at 60°, and 36,000 parts of boiling water for solution. Water thus impregnated has no effect on vegetable colours, but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one equivalent of magnesium 12·7, and one of oxygen 8=20·7. *Magnesium* is a white, very brilliant metal, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. There is a hydrate of magnesia, consisting of one equiv. of the earth and one of water. Magnesia forms with nitric and muriatic acids, salts which are soluble in alcohol and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydrate, and by the carbonates of potassa and soda as a carbonate; but it is not precipitated by the alkaline bicarbonates, nor by common carbonate of ammonia.

Magnesia is liable to contain, as impurities, undecomposed carbonate of magnesia, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. The presence of carbonate of magnesia is indicated by effervescence when the earth is dissolved in muriatic acid. Lime, which is a frequent impurity, and imparts to the magnesia a more strongly alkaline and more disagreeable taste, is detected by oxalate of ammonia or bicarbonate of potassa. Neither of these salts disturbs a neutral solution of pure magnesia in a dilute acid; but if lime be present, both produce precipitates, the former of oxalate, the latter of carbonate of lime. As magnesia is completely dissolved by muriatic acid, silica and other impurities insoluble in that acid would be left behind. Alumina is indicated by the production of a precipitate, when ammonia is added in excess to a solution of fifty grains of magnesia in a fluidounce of muriatic acid. (*Christison's Dispensatory*.) If the magnesia contain a soluble sulphate or carbonate from insufficient washing of the carbonate of magnesia from which it was prepared, the chloride of barium will reveal them by producing a precipitate with water digested on the magnesia.

Medical Properties and Uses. Magnesia is antacid and laxative; and is much employed, under the name of *calcined magnesia*, in dyspepsia, sick headache, gout, and other complaints attended with sour stomach and constipation. It is also a favourite remedy in the complaints of children, in which acidity of the primæ viæ is often a prominent symptom. Its antacid properties render it very useful in gravel attended with an excessive secretion of uric acid. Its advantages over carbonate of magnesia are that it may be given in a smaller dose, and does not occasion flatulence. The dose as a laxative is from thirty grains to a drachm, as an antacid merely, or antilithic, from ten to thirty grains twice a day. When it meets with no acid, it is apt to linger in the stomach or bowels, and should in this case be followed by lemonade. It should be administered in water or milk, and should be thoroughly triturated so as to render the mixture uniform.

Off. Prep. Trochisci Magnesiae, U. S.; Pulvis Rhei Compositus, Ed. W.

MAGNESIÆ SULPHAS PURUM. *Dub. Pure Sulphate of Magnesia.*

"Take of Commercial Sulphuric Acid *twenty-five parts*; Water *one hundred parts*; Carbonate of Magnesia *twenty-four parts*, or as much as may be sufficient to saturate the Acid. Mix the Sulphuric Acid and Water, and then gradually add the Carbonate of Magnesia. Lastly, evaporate the filtered liquor, so that crystals may form when it cools." *Dub.*

The sulphate of magnesia prepared in the large way is sufficiently pure for medical purposes; and the above process, therefore, is superfluous. W.

MELLITA.

Preparations of Honey.

Honey is used in pharmacy only as the vehicle of more active medicines. It is said to have this advantage over syrup, that its preparations are less apt to become candied; but as it contains principles which disagree with the stomachs of many persons, and as its variable consistence prevents the same exact precision in regard to proportion as is attainable with a solution of pure sugar, it is at present little employed. The preparations in which honey and vinegar are combined, are called *Oxymels*.

Medicated honeys are of a proper consistence, if, when a small quantity, allowed to cool upon a plate, is divided by the edge of a spoon, the portions do not readily coalesce. A more accurate criterion, however, is their specific gravity, which should be 1.319 (35° B.) at ordinary temperatures, and 1.261 (30° B.) at the boiling point of water. W.

MEL DESPUMATUM. *U. S., Dub. Clarified Honey.*

Take of Honey *any quantity*. Melt it by means of a water-bath, and then remove the scum." *U. S., Dub.*

Honey by the heat of the water-bath becomes so fluid, that the wax and other lighter impurities which it contains rise to the surface, and may be skimmed off; while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom.

The following method of clarifying honey is practised in France. Take of white honey 3000 parts; water 750 parts; carbonate of lime, powdered and washed, 96 parts. Mix them in a suitable vessel, and boil for three minutes, stirring constantly. Then add 96 parts of animal charcoal previously washed, heated to redness, powdered, and sifted, and boil for a few minutes. Lastly, add the whites of two eggs beat up with 500 parts of water, and bring the liquid to the boiling point. Withdraw the vessel from the fire, and, after the mixture has cooled for fifteen minutes, strain it through flannel, and repeat the straining till the liquid passes perfectly clear. Should it not have the proper consistence, it should be concentrated sufficiently by a quick boiling. The French Codex simply directs six pounds of white honey to be heated with three pounds of water, skimmed, concentrated to 30° B. while boiling hot, and then strained through flannel.

The following process for clarifying common honey was proposed by M. Borde, and approved by the Society of Pharmacy at Paris. Take of common honey 5000 parts; vegetable charcoal, in powder, 320 parts; animal charcoal, in powder, 160 parts; nitric acid of 30° or 32° Baumé 40 parts; water 320 parts. Rub the two kinds of charcoal, in a porcelain mortar, with the water and acid; then add the honey, and put the whole into a tinned pan. Place the vessel over the fire, and allow it to remain for eight

or ten minutes without suffering it to boil; then add 1600 parts of milk in which the white of an egg has been beaten, and boil for four or five minutes. Remove the liquid from the fire, and pass it through a strainer in a warm place, repeating the straining if the first portions are not clear. Of the nitric acid employed in the process, a portion is saturated by the lime of the animal charcoal, and the remainder unites with the caseous matter of the milk, which it thus causes to coagulate; none remains in the honey. (*Dict. Des Drogues.*)

Honey clarified by these processes is as clear and colourless as syrup made with sugar, but still retains a peculiar flavour. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

Off. Prep. Confectio Aromatica, *U. S.*; Confectio Opii, *U. S.*; Confectio Rosæ, *U. S.*, *Dub.*; Conserva Rutæ, *Dub.*; Mel Boracis, *Dub.*; Mel Præparatum, *U. S.*; Mel Rosæ, *U. S.*, *Dub.*; Oxymel, *Dub.*; Oxymel Colchici, *Dub.*; Oxymel Scillæ, *U. S.*, *Dub.*; Pilulæ Ferri Carbonatis, *U. S.*; Tinctura Opii Camphorata, *U. S.* W.

MEL PRÆPARATUM. *U. S.* Prepared Honey.

“Take of Clarified Honey *half a pint*; Diluted Alcohol *a pint*; Prepared Chalk *half an ounce*. Having mixed the Honey and Diluted Alcohol, add the Prepared Chalk, and allow the mixture to stand for two hours, occasionally stirring it. Then heat it to ebullition, filter, and by means of a water-bath evaporate the clear liquor, so that when cold it may have the specific gravity 1.32.” *U. S.*

This process was intended to prepare honey, so as to fit it better for addition to the protosalts of iron, including the protiodide and protochloride, in order to prevent the absorption of oxygen. The prepared chalk neutralizes any acid which it may contain, while impurities insoluble in diluted alcohol are left behind, and the honey deprived of colour.

Off. Prep. Liquor Ferri Iodidi, *U. S.* W.

MEL BORACIS. *Lond., Ed., Dub.* Honey of Borax.

“Take of Borax, in powder, *a drachm*; Honey [Clarified Honey, *Dub.*] *an ounce*. Mix them.” *Lond., Ed., Dub.*

This preparation might well be left to extemporaneous prescription. It is used in apthous ulcerations of the mouth. W.

MEL ROSÆ. *U. S., Lond., Ed., Dub.* Honey of Roses.

“Take of Red Roses *two ounces*; Clarified Honey *two pints*; boiling Water *a pint and a half*. Macerate the Roses in the Water for two hours, and strain; then add the Honey, and evaporate by means of a water-bath to the proper consistence. The specific gravity of the Honey of Roses should be 1.32.” *U. S.*

The *London College* macerates *four ounces* of dried red roses in *two pints and a half* [Imperial measure] of boiling water for six hours, then strains, adds *five pounds* of honey, and evaporates by a water-bath to the proper consistence. The *Edinburgh College*, operating upon the same materials, in the same quantities, infuses the petals for six hours in the water, strains with expression, allows the impurities to subside, decants the clear liquor, adds the honey, and evaporates in the vapour-bath to the consistence of syrup, removing the scum which forms. The *Dublin* process corresponds with the London, except that *three wine pints* of water are used instead of two and a half Imperial pints, and the scum which forms during the evaporation is directed to be removed.

This preparation has the flavour of the rose with its slight astringency, and forms a pleasant addition to the gargles employed in inflammation and ulceration of the mouth and throat. W.

OXYMEL. *Lond., Dub. Oxymel.*

“Take of Honey *ten pounds*; Acetic Acid *a pint and a half* [Imperial measure]. Mix the Acid with the Honey previously heated.” *Lond.*

The *Dublin College* takes *two pounds* of crude honey, and *a pint* of distilled vinegar; and boils them to the consistence of syrup, removing the scum as it rises.

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines, and to impart flavour to drinks in febrile complaints. If it be prepared according to the London formula, care must be taken to employ the acetic acid of the strength directed by that College. W.

OXYMEL COLCHICI. *Dub. Oxymel of Colchicum.*

“Take of the fresh Bulb of Colchicum, cut into thin slices, *an ounce*; Distilled Vinegar *a pint*; Clarified Honey *two pounds*. Macerate the Colchicum with the Vinegar, in a glass vessel, for forty-eight hours. Strain the liquor, with strong expression, from the root, and add the Honey. Lastly, boil the mixture, frequently stirring it with a wooden spatula, to the consistence of a syrup.” *Dub.*

This preparation is seldom used in this country, and could not indeed be conveniently prepared, according to the above directions, as we have not the fresh bulbs. It is in no respect superior to the wine of colchicum, by which it has been superseded. The dose is a fluidrachm, repeated twice a day, and gradually increased till it produces the desired effect. W.

OXYMEL CUPRI SUBACETATIS. *Dub. LINIMENTUM ÆRUGINIS.* *Lond. Oxymel of Subacetate of Copper.*

“Take of Verdigris in powder, [Prepared Subacetate of Copper, *Dub.*] *an ounce*; Vinegar [Distilled Vinegar, *Dub.*] *seven fluidounces*; Honey [Clarified Honey, *Dub.*] *fourteen ounces*. Dissolve the Verdigris in the Vinegar, and strain the solution through linen; then gradually add the Honey, and boil down to the proper consistence.” *Lond., Dub.*

This is an external stimulant and escharotic, and was formerly called *mel Ægyptiacum*. It is employed either undiluted or mixed with some mild ointment, to destroy fungous granulations, or to repress their growth. In the latter state, it is a useful stimulant to flabby, indolent, and ill conditioned ulcers, and largely diluted with water has been used as a gargle in venereal ulcerations of the mouth and throat. It is sometimes also applied undiluted to those ulcers in the fauces by means of a camel's-hair pencil. W.

OXYMEL SCILLÆ. *U. S., Lond., Dub. Oxymel of Squill.*

“Take of Clarified Honey *three pounds*; Vinegar of Squill *two pints*. Mix them, and evaporate by means of a water-bath to the proper consistence. The specific gravity of Oxymel of Squill should be 1.32.” *U. S.*

The *London College* takes *three pounds* of honey and *a pint and a half* (Imperial measure) of vinegar of squill; the *Dublin*, *three pounds* of clarified honey and *two pints* of vinegar of squill; both boil in a glass vessel, with a slow fire, to the proper consistence.

This preparation has the virtues of squill, but is in no respect superior to the syrup. Prepared according to the directions of the London and Dublin Colleges, it would be very liable to be injured by heat. It is chiefly used as an expectorant in chronic catarrh, humoral asthma, hooping

cough, and generally in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration. The dose is from one to two fluidrachms. In large doses it is emetic, and as such may sometimes be given with advantage in infantile croup and catarrh. W.

MISTURÆ.

Mixtures.

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in watery fluids by the intervention of gum Arabic, sugar, the yolk of eggs, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is sometimes called an *emulsion*. The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines; and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of a uniform and perfect mixture. As a general rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the watery vehicle is added. In the case of the liquid balsams and oils, if gum Arabic be employed as the intermedium, it should be previously brought to the state of mucilage of the consistence directed in the U. S. Pharmacopœia. The white of eggs is frequently ordered by physicians as the suspending substance, but it is inferior for this purpose to the yolk, or to gum Arabic. When the white is used it should be well beaten, and incorporated with the oleaginous or balsamic substance before the water is added.* Mixtures are generally the objects of extemporaneous prescription; but a few have been deemed of sufficient importance to merit a place in the Pharmacopœias. They should be prepared only when wanted for use.

MISTURA ACACIÆ. *Ed.* EMULSIO ARABICA. *Dub.* *Gum Arabic Mixture. Gum Arabic Emulsion.*

“Take of Mucilage [of Gum Arabic] *three fluidounces*; Sweet Almonds *one ounce and two drachms*; Pure Sugar *five drachms*; Water *two pints* [Imperial measure.] Steep the Almonds in hot water and peel them; beat them to a smooth pulp in an earthenware or marble mortar, first with the Sugar, and then with the Mucilage; add the Water gradually, stirring constantly; then strain through linen or calico.” *Ed.*

“Take of Gum Arabic, in powder, *two drachms*; Sweet Almonds, blanched, Refined Sugar, each, *half an ounce*; Water *a pint*. Dissolve the Gum in the heated Water, and when the solution is almost cold, gradually pour it upon the Almonds, previously well beaten with the Sugar, triturating at the same time so as to form an emulsion; then strain.” *Dub.*

Used as a demulcent in the dose of one or two fluidounces, or as a vehicle for various medicines in inflammatory affections of the bronchial, alimentary, and urinary mucous membranes. W.

* For some good practical observations upon the preparation of mixtures, the reader is referred to a communication published in the Journal of the Philadelphia College of Pharmacy, vol. iv. p. 11, by W. Hodgson, Jun.

MISTURA AMMONIACI. *U.S., Lond., Dub. Ammoniac Mixture.*

"Take of Ammoniac *two drachms*; Water *half a pint*. Rub the Ammoniac with the Water gradually added, until they are thoroughly mixed." *U.S.*

The *London College* takes *five drachms* of ammoniac, and a *pint* [Imperial measure] of water, and proceeds as above. The *Dublin College* directs a *drachm* of ammoniac to be rubbed with *eight fluidounces* of pennyroyal water, and the mixture to be strained through linen.

In this mixture the insoluble part of the ammoniac is suspended by means of the gum, imparting a milky appearance to the preparation, which, from this circumstance, was formerly called *lac ammoniaci* or *milk of ammoniac*. The greater portion of the resin subsides upon standing. The mixture is slightly curdled by acids. The dose is from one to two table-spoonfuls.

W.

MISTURA AMYGDALÆ. *U.S., Lond. MISTURA AMYGDALARUM. Ed., Dub. Almond Mixture. Almond Emulsion.*

"Take of Sweet Almonds *half an ounce*; Gum Arabic, in powder, *half a drachm*; Sugar *two drachms*; Distilled Water *eight fluidounces*. Macerate the Almonds in water, and, having removed their external coat, beat them with the Gum Arabic and Sugar, in a marble mortar, till they are thoroughly mixed; then rub the mixture with the Distilled Water gradually added, and strain." *U.S.*

"Take of Almond Confection *two ounces and a half*; Distilled Water *a pint* [Imperial measure]. To the Almond Confection, while rubbing it, gradually add the Water, till they are mixed; then strain through linen." *Lond.*

"Take of Conserve of Almonds *two ounces*; Water *two pints* [Imp. measure]. Add the Water gradually to the Confection, triturating constantly; and then strain through linen or calico. Or,

"Take of Sweet Almonds *one ounce and two drachms*; Pure Sugar *five drachms*; Mucilage *half a fluidounce*; Water *two pints* [Imp. measure]. Steep the Almonds in hot water and peel them; and proceed as for the *Mistura Acaciæ*." *Ed.*

"Take of Sweet Almonds, blanched, *an ounce and a half*; Bitter Almonds *two scruples*; Refined Sugar *half an ounce*; Water *two pints and a half*. Triturate the Almonds with the Sugar, adding the Water by degrees, and strain." *Dub.*

Of the above modes of preparing the almond emulsion, we prefer that of the *U. S. Pharmacopœia*, which was very properly substituted, in the last edition of that work, for the mixture made with almond confection directed in the previous edition. This confection very speedily spoils if kept, and it would be a very unnecessary complication of the process to prepare it each time that the emulsion might be wanted. The *London* and first *Edinburgh* processes are, therefore, objectionable. In the second process of the latter College, mucilage is employed instead of powdered gum Arabic, which is preferable, as less likely to have undergone change. The *Dublin* process is distinguished by the use of bitter almonds, which, though in too small proportion for medicinal effect, impart a flavour which is not acceptable to all individuals, and should be left to the choice of the prescriber. The preparations, however, of the different *Pharmacopœias* are essentially the same. The gum Arabic in these formulæ is introduced not so much for its demulcent properties as to assist in the suspension of the

insoluble ingredients of the almonds. In the *Misturæ Acaciæ* above described it is the prominent ingredient. The same formula will answer for the preparation of an *emulsion of bitter almonds*, which may be preferred to the present when a slight influence of hydrocyanic acid is desired.

The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water; and with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when not very impure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The mixture is not permanent. Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. It has a close analogy to milk in chemical relations as well as in appearance. The preparation, in warm weather, soon becomes sour, and unfit for use.

The almond mixture has a bland taste, and may be used as an agreeable, nutritive demulcent in catarrhal and dysenteric affections, and irritation of the urinary passages. To be of service it must be freely employed. From two to eight fluidounces may be taken at once. It is occasionally employed as the vehicle of less agreeable medicines; but should not be used in connexion with any considerable quantity of tinctures, acidulous salts, or other substances containing an excess of acid. W.

MISTURA ASSAFÆTIDÆ. U. S., *Lond.* MISTURA ASSÆFÆTIDÆ. *Dub.* *Assafetida Mixture.*

“Take of Assafetida *two drachms*; Water *half a pint*. Rub the Assafetida with the Water gradually added, until they are thoroughly mixed.” U. S.

The *London College* directs *five drachms* of assafetida and a *pint* [Imperial measure] of water; the *Dublin*, *one drachm* of assafetida and *eight fluidounces* of pennyroyal water.

This mixture, from its whiteness and opacity, is frequently called *lac assafætidx*, or *milk of assafetida*. It is, as a general rule, the best form for the administration of this antispasmodic, being less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable smell and taste are, however, objections, which induce a frequent preference of the last mentioned preparation. It is very often employed as an enema. The dose is from one to two tablespoonfuls frequently repeated. From two to four fluidounces may be given by the rectum. W.

MISTURA CAMPHORÆ CUM MAGNESIÂ. *Ed.*, *Dub.* *Mixture of Camphor with Magnesia.*

“Take of Camphor *twelve grains*; Carbonate of Magnesia *half a drachm*; Water *six ounces* [fluidounces]. Triturate the Camphor with the Magnesia, adding the Water gradually, and mix.” *Dub.*

The *Edinburgh College* takes *ten grains* of camphor, *twenty-five grains* of carbonate of magnesia, and *six fluidounces* of water, and proceeds as above.

This differs from the *Aqua Camphoræ* of the U. S. Pharmacopœia, in which, though the camphor is dissolved by the intervention of magnesia, the latter is afterwards separated by filtration. In the above mixture the

carbonate of magnesia is retained; and an anodyne, antacid, and laxative draught is formed, which, though it may sometimes be given with advantage, hardly deserves a place among the officinal preparations. W.

MISTURA CASCARILLÆ COMPOSITA. *Lond. Compound Mixture of Cascarella.*

"Take of Infusion of Cascarella *seventeen fluidounces*; Vinegar of Squill *a fluidounce*; Compound Tincture of Camphor *two fluidounces*. Mix them." *Lond.*

This mixture combines tonic, expectorant, and anodyne properties, and is said to have been employed advantageously in chronic bronchial inflammation; but it would have been better left to extemporaneous prescription. The dose is from one to two fluidounces twice or thrice daily. W.

MISTURA CREASOTI. *Ed. Creasote Mixture.*

"Take of Creasote and Acetic Acid, of each, *sixteen minims*; Compound Spirit of Juniper and Syrup, of each, *one fluidounce*; Water *fourteen fluidounces*. Mix the Creasote with the Acid, then gradually the Water, and lastly the Syrup and Spirit." *Ed.*

The dose of this mixture is a fluidounce containing a minim of creasote.

MISTURA CRETÆ. *U. S., Lond., Ed., Dub. Chalk Mixture.*

"Take of Prepared Chalk *half an ounce*; Sugar [refined], Gum Arabic in powder, each, *two drachms*; Cinnamon Water, Water, each, *four fluidounces*. Rub them together till they are thoroughly mixed." *U. S.*

The *London College* orders *half an ounce* of prepared chalk, *three drachms* of sugar, *a fluidounce and a half* of mixture [mucilage] of gum Arabic, and *eighteen fluidounces* of cinnamon water; the *Dublin College*, *half an ounce* of prepared chalk, *three drachms* of refined sugar, *an ounce* of mucilage of gum Arabic, and *a pint* of water. The *Edinburgh College* takes *ten drachms* of prepared chalk, *five drachms* of pure sugar, *three fluidounces* of mucilage of gum Arabic, *two ounces* [fluidounces] of spirit of cinnamon, and *two Imperial pints* of water; rubs the chalk, mucilage, and sugar together, and then adds gradually the water and spirit of cinnamon.

This mixture is a convenient form for administering chalk, and is much employed in looseness of the bowels accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency. The dose is a tablespoonful frequently repeated. W.

MISTURA FERRI AROMATICA. *Dub. Aromatic Mixture of Iron.*

"Take of Crown Bark, in coarse powder, *an ounce*; Columbo Root, sliced, *three drachms*; Cloves, bruised, *two drachms*; Iron filings *half an ounce*. Digest for three days in a close vessel, with occasional agitation, with such a quantity of Peppermint Water as will yield a mixture of *twelve ounces* after filtration; then add, of Compound Tincture of Cardamom *three ounces*; Tincture of Orange Peel *three drachms*." *Dub.*

This is an aromatic infusion of Peruvian bark and columbo, and has not the slightest claim to the title given it in the Pharmacopœia; as it contains but a very small proportion of iron, and that in a state of solution, not of mixture. In consequence of the action of some of the vegetable principles upon the filings, enough of the metal is taken up to impart a greenish-black colour to the liquor; but the quantity is not appreciable, as the filings seem to be scarcely diminished by the process. The preparation may be given as a tonic in the dose of one or two fluidounces. W.

MISTURA FERRI COMPOSITA. U. S., Lond., Ed., Dub.
Compound Mixture of Iron.

“Take of Myrrh, a *drachm*; Carbonate of Potassa *twenty-five grains*; Rose Water *seven fluidounces and a half*; Sulphate of Iron, in powder, a *scruple*; Spirit of Lavender *half a fluidounce*; Sugar [refined] a *drachm*. Rub the Myrrh with the Rose Water gradually added; then mix with these the Spirit of Lavender, Sugar, and Carbonate of Potassa, and lastly, the Sulphate of Iron. Pour the mixture immediately into a glass bottle, which is to be well stopped.” *U. S.*

“Take of Myrrh, in powder, *two drachms*; Carbonate of Potassa a *drachm*; Rose Water *eighteen fluidounces* [Imperial measure]; Sulphate of Iron, in powder, *two scruples and a half*; Spirit of Nutmeg a *fluidounce*; Sugar *two drachms*. Rub the Myrrh with the Spirit of Nutmeg and Carbonate of Potassa; and to these, while rubbing, add first the Rose Water with the Sugar, and then the Sulphate of Iron. Put the mixture immediately into a suitable glass vessel, and stop it.” *Lond.*

The *Edinburgh* process differs from the London only in using the myrrh bruised, and the sulphate of iron in coarse powder. The *Dublin College* takes a *drachm* of myrrh, *twenty-five grains* of carbonate of potassa, *seven ounces and a half* of rose-water, a *scruple* of sulphate of iron, *half an ounce* of spirit of nutmeg, and a *drachm* of refined sugar; and proceeds as directed by the London College.

This is very nearly the same with the celebrated tonic or antihectic myrrh mixture of Dr. Griffith. The sulphate of iron is decomposed by the carbonate of potassa, with the production of sulphate of potassa and carbonate of protoxide of iron; while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish colour, which it loses upon exposure to the air, in consequence of the conversion of the protoxide of iron of the carbonate into the red or sesquioxide. It may, however, be kept for some time without change, if the vessel in which it is contained be well closed; but the best plan is to prepare it only when it is wanted for use. The sugar contained in it probably contributes somewhat to retard the further oxidation of the protoxide of iron, and if considerably increased in amount would act still more efficiently. The finest pieces of myrrh in lump should be selected, and rubbed down for the occasion with a little of the rose water; as the powdered myrrh of the shops is often impure, and does not make a good mixture.

This mixture is a good tonic in debility of the digestive organs, especially when attended with derangement of the menstrual function. Hence it is used with advantage in chlorosis and hysterical affections. It is also much employed in the hectic fever of phthisis and chronic catarrh. It is contra-indicated by the existence of inflammation of the gastric mucous membrane. The dose is one or two fluidounces two or three times a day. *W.*

MISTURA GENTIANÆ COMPOSITA. Lond. Compound
Mixture of Gentian.

“Take of Compound Infusion of Gentian *twelve fluidounces*; Compound Infusion of Senna *six fluidounces*; Compound Tincture of Cardamom *two fluidounces*. Mix them.” *Lond.*

We can discover no propriety in making such formulæ as the above official. Numerous combinations prescribed every day by physicians are quite as much entitled to a place in the Pharmacopœia. The dose is one or two fluidounces. *W.*

MISTURA GUAIACI. *Lond., Ed. Guaiac Mixture.*

“Take of Guaiacum Resin *three drachms*; Sugar *half an ounce*; Mixture of Gum Arabic *half a fluidounce*; Cinnamon Water *nineteen fluidounces*. Rub the Guaiacum Resin with the Sugar, then with the Mixture of Gum Arabic, and to these, while rubbing, add gradually the Cinnamon Water.” *Lond.*

The *Edinburgh* process differs only in using an additional *half fluid-ounce* of cinnamon water.

From one to three tablespoonfuls of this mixture may be given for a dose, and repeated two or three times a day, or more frequently. *W.*

MISTURA MOSCHI. *Lond. Musk Mixture.*

“Take of Musk, Gum Arabic in powder, Sugar, each, *three drachms*; Rose Water *a pint* [Imperial measure]. Rub the Musk with the Sugar, then with the Gum, adding gradually the Rose Water.” *Lond.*

The musk should be thoroughly rubbed with the gum and sugar before the addition of the water. The mixture will be more permanent if made with twice the quantity of gum directed. The dose is a fluidounce. *W.*

MISTURA SCAMMONII. *Ed. Scammony Mixture.*

“Take of Resin of Scammony *seven grains*; unskimmed Milk *three fluidounces*. Triturate the Resin with a little of the Milk, and gradually with the rest of it till a uniform emulsion is formed.” *Ed.*

This *Edinburgh* officinal is an imitation of a mixture recommended by Planche. The resin of scammony mixes admirably with the vehicle, and forms an emulsion scarcely distinguishable in appearance or taste from rich milk. Of course, it should be prepared only when wanted for immediate use. The whole is to be taken for a dose. *W.*

MISTURA SPIRITUS VINI GALLICI. *Lond. Brandy Mixture.*

“Take of Brandy, Cinnamon Water, each, *four fluidounces*; the yolks of *two Eggs*; Sugar [refined] *half an ounce*; Oil of Cinnamon *two minims*. Mix them.” *Lond.*

A stimulant and nutritive draught, applicable to the sinking stage of low forms of fever, but scarcely entitled to a place in the Pharmacopœia. *W.*

MORPHIA.

*Preparations of Morphia.*MORPHIA. *U. S., Lond. Morphia.*

“Take of Opium, sliced, *a pound*; Distilled Water, Alcohol, each, *a sufficient quantity*; Solution of Ammonia *six fluidounces*. Macerate the Opium with four pints of Distilled Water for twenty-four hours, and, having worked it with the hand, digest for twenty-four hours and strain. In like manner, macerate the residue twice successively with Distilled Water, and strain. Mix the infusions, evaporate to six pints, and filter; then add first five pints of Alcohol, and afterwards three fluidounces of the Solution of Ammonia, previously mixed with half a pint of Alcohol. After twenty-four hours, pour in the remainder of the Solution of Ammonia, mixed, as before, with half a pint of Alcohol; and set the liquor aside for twenty-four hours, that crystals may form. To purify these, boil them with two pints of Alcohol till they are dissolved, filter the solution, while hot, through Animal Charcoal, and set it aside to crystallize.” *U. S.*

“Take of Hydrochlorate [Muriate] of Morphia *an ounce*; Solution of Ammonia *five fluidrachms*; Distilled Water *a pint* [Imperial measure]. To the Solution of Ammonia, with an ounce of Distilled Water, add the Hydrochlorate of Morphia previously dissolved in a pint of the Water, shaking them together. Wash the precipitate with distilled water, and dry it with a gentle heat.” *Lond.*

The London process consists in a simple decomposition of the muriate of morphia by means of ammonia, which takes the muriatic acid and remains in solution as muriate of ammonia, while the morphia, being insoluble, is deposited. The process of the U. S. Pharmacopœia will be better understood by a previous acquaintance with the properties and chemical relations of the substance in question.

Morphia crystallizes from alcohol in the form of small, colourless, shining crystals. It is inodorous and bitter. Exposed to a moderate heat it loses its water of crystallization and the crystalline form, becoming white and opaque. At a higher temperature it melts, forming a yellowish liquid, which becomes white and crystalline upon cooling. Heated in the open air it burns with a bright flame, and at a red heat is wholly dissipated. It is insoluble or nearly so in cold water, soluble in rather less than 100 parts of water at 212°, slightly soluble in cold alcohol, and freely so in boiling alcohol, which deposits it upon cooling. It is dissolved also by the fixed and volatile oils, but very slightly if at all by ether. Its solution restores the blue colour of litmus paper reddened by acids, and turns the yellow of turmeric to brown. With the acids it forms salts, which are generally soluble, and are decomposed by the alkalies. The solutions of potassa and soda are also capable of dissolving morphia, which is precipitated slowly on exposure to the air, in consequence of the absorption of carbonic acid. Solution of ammonia has to a certain extent the same solvent power; and hence the necessity, in precipitating morphia by this alkali, not to employ it in great excess. Morphia and its salts, by the contact of nitric acid, assume a blood-red colour, which ultimately changes to yellow. When added to a solution of iodic acid, or an acidulous iodate, they redden the liquid and set iodine free. (*Serullas.*) They assume a fine blue colour with the sesquichloride of iron, and the salts of the sesquioxide; at least this is true of morphia, its acetate and oxalate; and the same effect will be produced by the other salts if previously decomposed by an alkali. Water, acids, and alkalies, added in large quantity to the blue compound formed, destroy its colour. According to Pelletier, however, there occasionally exists in opium a principle which he calls pseudomorphia, which becomes red under the action of nitric acid and changes the sesquisalts of iron blue, and yet is destitute of poisonous properties; so that the occurrence of these phenomena, in any medico-legal case, cannot be considered as certain evidence of the presence of morphia. (See *Am. Journ. of Pharm.* viii. 77.) Morphia is precipitated from its solutions by potassa or soda, and redissolved by an excess of the alkali. Infusions of galls and other vegetable substances containing tannic acid precipitate morphia in the state of a tannate, which is soluble in acetic acid; but, according to Dublanc, the alkali is not precipitated by pure gallic acid. If ammonia be added to a mixture of the solutions of chlorine and morphia, a dark-brown colour is produced, which is destroyed by a further addition of chlorine. The proportion of the ingredients of morphia is somewhat differently given by different writers. According to the most recent authorities, anhydrous morphia consists of thirty-five equivalents of carbon 214·20, twenty of hydrogen 20, six of oxygen 48, and one of nitrogen 14·15=296·35, to which in the crystals are added two equiv. of water 18, or about 5·72 per cent.

Various processes for preparing morphia have been employed. In most of them the morphia is extracted from opium by maceration with water either pure or acidulated, is then precipitated by ammonia, and afterwards purified by the agency of alcohol, or by repeated solution in a dilute acid and precipitation. According to another plan, the morphia is removed from the infusion of opium by means of double decomposition, and obtained first in the form of a muriate, from which the alkali is separated by solution and precipitation. The former of these modes of proceeding will be noticed here, the latter under the head of muriate of morphia.

Sertürner, the discoverer of morphia, made an infusion of opium in distilled water, precipitated the morphia by ammonia in excess, dissolved the precipitate in dilute sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol and crystallization.

The process adopted in the French Codex is a modification of that of Sertürner. It is as follows. "Take of opium 1000 parts, solution of ammonia a sufficient quantity. Exhaust the opium, by means of cold water, of all its parts soluble in this menstruum. For this purpose, it is sufficient to treat the opium, four times consecutively, with ten parts of water to one of the drug, provided care be taken to macerate the opium for some hours, and to work it with the hands. Filter the liquors, and evaporate them to a quarter of their volume. Then add sufficient ammonia to render the liquor very sensibly alkaline. Boil for some minutes, always maintaining a slight excess of ammonia. Upon cooling, the morphia, impure and much coloured, will be precipitated in granular crystals, which are to be washed with cold water. Reduce this coloured morphia to powder, macerate it for twelve hours in alcohol of 24° Cartier (sp. gr. about 0.900); then decant the alcoholic liquid; dissolve the residuary morphia, already in great measure deprived of colour by the cold alcohol, in boiling alcohol of 33° Cartier (sp. gr. about 0.850); add to the solution a little animal charcoal, and filter. Upon cooling, the morphia crystallizes in colourless needles. In this state the morphia always retains some narcotina, to free it from which, boil it with sulphuric ether in a matrass with a long neck surmounted by a refrigerator."

The process of the U. S. Pharmacopœia is an improvement upon the above, and is essentially the same with that of Dr. Edward Staples, published in the Journal of the Philadelphia College of Pharmacy, Vol. I. p. 15. Without repeating a description of the process, we shall make such remarks upon its several steps, as appear to us likely to be of practical advantage. The employment of water as the solvent is justified by the almost universal practice. It is true that dilute acetic acid has sometimes been employed, and Vogel states that the product thus obtained is much greater than when water alone is used. But when the opium is properly comminuted, either by being reduced to a coarse powder when dry, or by being finely sliced, in its ordinary state, water alone will be found sufficiently to extract the morphia, by a protracted maceration or digestion in successive portions of water, assisted by kneading, as directed in the Pharmacopœia. The acids have this disadvantage, that they dissolve more of the narcotina than pure water, and thus render the ultimate product more impure; for the narcotina which is originally taken up continues associated with the morphia in all the subsequent steps of the process. It has been proposed to expose the opium to fermentation with water and yeast, in order to facilitate the extraction of the morphia. By this plan M. Blondeau succeeded in procuring more of the alkaline principle than he could obtain by the ordinary mode; and his results were confirmed by the experiments of MM. Robiquet and Guibourt. According to these latter chemists,

no alcohol is produced during the fermentation, which appears to act merely by disengaging the morphia from the combinations in which it naturally exists, and which tend to counteract the solvent power of the menstruum. Alcohol has been proposed as the solvent by M. Guillermond, but it is liable to the objection that it dissolves also the resin, a portion of which is afterwards precipitated with the morphia and embarrasses the process. Much of the resin, however, may be separated by distilling most of the alcohol from the tincture, and then adding water. The resin is precipitated, and the liquor may now be treated in the same manner as the aqueous infusion. On the whole, however, the officinal mode of extraction will probably be found most satisfactory; and Mohr states that opium thus exhausted yields no more morphia even to muriatic acid; but he recommends that each maceration should be followed by strong expression. The solution of opium having been prepared, the next object is to decompose the meconate or other salt of morphia contained in it. For this purpose solution of ammonia is added, which seizes the acid and precipitates the vegetable alkali; but much colouring matter is thrown down along with the latter, occasioning some trouble to separate it, unless measures are taken to obviate this effect. The object is gained by mixing the infusion with alcohol, previously to the addition of the ammonia, and by employing the solution of ammonia itself in connexion with alcohol, as directed in the Pharmacopœia. This is the peculiarity and chief merit of the process of Dr. Staples. By the presence of the alcohol in all parts of the liquor, the colouring matter is dissolved as soon as it is separated by the ammonia, and the morphia is thus precipitated in a much purer state. The advantage of adding the ammonia in separate portions is, that the morphia being thus more slowly disengaged, can be more completely deprived of its impurities by the alcohol of the mixture, than if the whole were liberated at once. It is necessary to be careful that the ammonia be not in great excess, as it has the property, under these circumstances, of dissolving the morphia in some degree, and will therefore lessen the product, while waste is incurred by its own unnecessary consumption. Very little more should be added than is sufficient to saturate the acid present. The solution of ammonia of the shops is often much below the officinal standard, and this should always be attended to in the process. Alcohol is mixed with the ammonia before it is added, in order that every particle of the separated morphia may come in contact with the particles of this fluid, and thus have the opportunity of being deprived of colouring matter. The crystals of morphia obtained by this first operation have a light yellowish colour, and are much purer than when no alcohol is added to the infusion before the precipitation by ammonia. According to Dr. Staples, opium yields from 10 to 12½ per cent. of these crystals. Their purification by solution in boiling alcohol, is the concluding step of the operation. The liquid, on cooling, deposits the morphia in a crystalline state and nearly free from colour. As cold alcohol retains a portion of the morphia in solution, it should not be employed in too large a quantity. Alcohol somewhat reduced by water, is preferable to the highly rectified spirit; as it is less capable of holding the morphia in solution when cold. It is sufficiently strong for the purpose at 25° Baumé (sp. gr. 0.9032). The impure morphia remaining in the alcohol may be obtained by distilling off the latter, and when sufficiently accumulated may be purified by a separate operation. The crystals of morphia may also be purified by solution in dilute sulphuric acid, digestion with animal charcoal deprived of earthy matter, filtration, and precipitation by ammonia. If alcohol be added to the solution previously to the ammonia, the digestion with animal charcoal may be dispensed with, as the alcohol retains the

colouring matter. Morphia procured in this way always contains narcotina, from which it may be freed by ether as directed in the French Codex process, or in some of the modes hereafter to be indicated.

Magnesia was employed by Robiquet, instead of ammonia. To the solution obtained by macerating opium in water, he added magnesia in the proportion of 5 parts to 100 of the opium used; collected the precipitate on a filter; and, having washed it with water and allowed it to dry, removed it from the filter, powdered it, and digested it repeatedly in alcohol of 22° Baumé, until this liquid ceased to extract any thing. The colouring matter being thus removed, the residue was treated with successive portions of boiling alcohol, which dissolved the morphia, and being filtered and allowed to cool, deposited it in crystals. The mother liquors afforded a fresh supply by evaporation at a low temperature. If still coloured, the morphia was purified by boiling it with alcohol and animal charcoal, filtering the liquid while hot and allowing it to crystallize. But the process of Robiquet was soon abandoned, as it was found to occupy more time, to require a greater consumption of alcohol, and to be attended with a greater loss of morphia in consequence of the previous washing, than the processes in which ammonia was employed as the precipitant.

A process for extracting morphia without the employment of alcohol was devised by MM. Henry Jun. and Plisson. The opium was exhausted by water acidulated with muriatic acid; the resulting solution was sufficiently concentrated, then filtered, and decomposed by ammonia; the precipitate was washed and treated with muriatic acid to saturation; and the muriatic solution was boiled with animal charcoal, filtered, and evaporated to the point of crystallization. The crystals of muriate of morphia thus obtained were pressed, purified by repeated solution and crystallization, and finally decomposed by ammonia. (*Journ. de Chim. Med.*, Mars 1828.)

More recently, Mohr has proposed a process founded upon the solubility of morphia in water mixed with lime, which he recommends highly as the shortest and easiest method of procuring the alkali, without the use of alcohol, and without the possibility of contamination from narcotina. Opium is three or four times successively macerated with three parts of water, and each time strongly expressed. The liquors are then added to a boiling hot milk of lime, containing a quantity of lime equal to about a sixth or a quarter of the opium used; and the mixture is boiled for a few minutes. It is then strained through linen, and the residue washed with boiling water and expressed. The whole of the narcotina is left behind, as not a trace of it can be discovered in the filtered liquor. The liquor thus obtained is evaporated till reduced to about double the weight of the opium, then quickly filtered through paper, and heated to ebullition. Muriate of ammonia is now added to it in the proportion of 1 part to 16 of the opium used; and the morphia is abundantly precipitated. The use of animal charcoal is unnecessary in the process, as the lime acts even more powerfully as a decolorizing agent. The crystallized morphia obtained is somewhat coloured, but may be rendered quite pure by solution in dilute muriatic acid, boiling with milk of lime, filtration, and precipitation by muriate of ammonia. (*Annal. der Pharm.* xxxv. 119, and *Am. Journ. of Pharm.* xiii. 60.)

Various other processes, or modifications of those above described, have been proposed; but for the preparation of small quantities of morphia by the apothecary, none are probably better adapted than that of the U. S. Pharmacopœia, unless indeed the plan of Mohr should be found to equal the representations in its favour.

It has been already stated that morphia, obtained in the ordinary manner,

contains a considerable proportion of narcotina. It is highly probable that this ingredient exercises no influence, either beneficial or injurious, upon the operation of the morphia; but as the contrary has been supposed, various methods have been employed for separating it. The simplest and easiest is to submit the mixture to the action of sulphuric ether, which dissolves the narcotina and leaves the morphia. The agency of acetic acid may also be resorted to. Distilled vinegar, or diluted acetic acid of the same strength, will dissolve the morphia and leave the narcotina, and the former may be recovered from the acetic solution by saturating the acid with ammonia. Another mode is to dissolve the mixed bases in strong acetic acid (of 7° Baumé, or sp. gr. 1.0511, for example), and expose the solution to heat. The narcotina is deposited, and the morphia, remaining in solution, may be precipitated by diluting the liquid and adding ammonia. (See *Journ. de Pharm.* xvii. p. 640.) Wittstock advises one of the following methods. Dissolve the impure morphia in dilute muriatic acid, evaporate to the point of crystallization, and strongly express the crystals, which consist solely of the muriate of morphia, the narcotina being retained in the mother waters:—or, saturate the muriatic solution with common salt, which will render the liquor milky, and cause the narcotina to separate after some days; then precipitate the morphia by ammonia:—or, pour into the diluted muriatic solution a weak ley of caustic potassa, which, if in slight excess, will dissolve the morphia at the moment of its separation, while the narcotina is precipitated; then immediately filter the liquor, and separate the morphia by neutralizing the alkali. If the potassa be in considerable excess a small portion of the narcotina is redissolved. (*Berzelius. Traité de Chimie.*) Mohr recommends to dissolve the morphia in dilute muriatic acid, and to boil the solution with lime, which throws down the narcotina and holds the morphia dissolved. The liquid being filtered yields the morphia upon the addition of sal ammoniac. (*Annal. der Pharm.* xxv. 123.)

The proportion of pure morphia which Turkey opium is capable of affording, varies from nine per cent. or less, to fourteen per cent., according to the quality of the drug; but much less than the least quantity mentioned is often obtained, in consequence of the incomplete exhaustion of the opium, or the loss in the process for preparing it.

Medical Properties. There can be no doubt that morphia is the chief, if not the exclusive narcotic principle of opium, from which, however, it differs somewhat in its mode of action. Whether the difference arises from the peculiar state of combination in which morphia exists in opium, or from other narcotic principles being associated with it, has not been determined; but the former would seem to be the probable cause, from the circumstance, that long before the discovery of this alkali, preparations of opium were habitually used, in which the properties of the medicine were somewhat similarly modified by the agency of vinegar, lemon-juice, or other vegetable acid. In consequence of its insolubility in water, morphia in its pure state is less certain in its effects than some of its saline compounds; as the mode and degree of its action must, in some measure, depend on the presence or absence of acid in the stomach, and perhaps on the peculiar character of the acid. Its salts are therefore always preferred. The acetate, sulphate, and muriate have been employed. Between these there is a great similarity of action, and what may be said of one, in regard to its therapeutical effects, will equally apply to the others. They have the anodyne, soporific, and diaphoretic properties of opium; but are less stimulant, less disposed to constipate the bowels, and less apt to leave behind them headache, nausea, or other unpleasant effect. They are usually also more acceptable to the

irritated stomach, and will often be retained, when opium or its tincture would be rejected. They are applicable to all cases where the object is to relieve pain, quiet restlessness, promote sleep, or allay nervous irritation in any shape; but are less efficient than opium in the suppression of morbid discharges, and as stimulants in low forms of disease. We have found them especially useful in the mania arising from intemperance. A great advantage which they possess is the convenience of their external application to blistered surfaces, and the certainty of their effects when thus applied. In cases which do not admit of the internal use of opium or its preparations, the acetate or sulphate of morphia, sprinkled, in triple the ordinary dose, upon a blistered surface denuded of the cuticle, will be found to exercise upon the system all the influence it is capable of exerting when taken into the stomach. Applied in this manner, these salts are peculiarly useful in relieving violent neuralgic pains, and controlling obstinate sickness of the stomach. When intended to act on the system through the medium of the skin, they should be applied preferably to the epigastrium; when to act locally, as near the affected part as possible. When given in doses nearly, but not quite sufficient to produce sleep, they sometimes give rise to a very troublesome condition of the brain, amounting almost to delirium; but this always subsides spontaneously, or vanishes immediately upon the increase of the dose.

In over-doses, morphia and its salts produce the symptoms of narcotic poisons, though not perhaps in the same degree with a quantity of opium, equivalent in anodyne effect. The toxicological treatment is precisely the same as in the case of laudanum. (See *Opium*.)

As the proportion of acid necessary to neutralize morphia is very small, the dose of the alkali is the same as that of its salts. One-sixth of a grain may be considered equivalent to a grain of opium of the medium strength.

Off. Prep. Morphiae Acetas, *U. S., Lond., Ed.*; Morphiae Murias, *U. S.*; Morphiae Sulphas, *U. S.* W.

MORPHIÆ ACETAS. *U. S., Lond., Ed. Acetate of Morphia.*

“Take of Morphia, in powder, freed from narcotina by boiling with Sulphuric Ether, *an ounce*; Distilled Water *half a pint*; Acetic Acid *a sufficient quantity*. Mix the Morphia with the Water; then carefully drop in the Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, to the consistence of syrup. Lastly, dry the Acetate with a gentle heat, and rub it into powder.” *U. S.*

“Take of Morphia *six drachms*; Acetic Acid *three fluidrachms*; Distilled Water *four fluidounces*. Mix the Acid with the Water, and pour the mixture upon the Morphia to saturation. Evaporate the solution with a gentle heat, so that crystals may form.” *Lond.*

“Take of Muriate of Morphia *any convenient quantity*. Dissolve it in *fourteen times its weight* of Warm Water, and when the solution is cool add Aqua Ammoniae gradually and with constant agitation until there is a permanent but faint odour of ammonia in the fluid. Collect the precipitate on a calico filter, wash it moderately with cold water, and dissolve it by means of a slight excess of Pyroligneous Acid [dilute acetic acid] *in twelve parts* of Warm Water from *every part* of Muriate of Morphia that was used. Concentrate the solution over the vapour-bath and set it aside to crystallize. Drain and squeeze the crystals, and dry them with a gentle heat. More Acetate of Morphia may be obtained on concentrating the mother liquor.” *Ed.*

In all these processes, Morphia is saturated with acetic acid; in the first two it is taken already prepared, in the last is procured by the decomposition of the muriate by means of ammonia. Acetic acid is employed in preference to vinegar for saturating the morphia, because it can leave no impurity in the resulting salt. The solution of the morphia in the water is an indication that it is saturated. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is requisite not to employ too great a heat in the evaporation, as the acetate is readily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphia. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals; but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphia in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. A less heat is thus required in the evaporation, and impurities in the morphia may often be detected, as they are apt to be insoluble in alcohol. To ascertain, in this case, whether the morphia is saturated, it is necessary to employ litmus paper, the blue colour of which should not be restored, if previously reddened by an acid. If the morphia used in preparing the acetate contain narcotina, it will be best to employ as the solvent distilled vinegar, or diluted acetic acid of the same strength, and to favour its solvent power by the application of heat. Under these circumstances it dissolves only the morphia, leaving the narcotina nearly or quite untouched. (See notice by *William Hodgson, Jun.*, in the *Journ. of the Phil. Col. of Pharm.* vol. v. p. 35.)

Acetate of morphia crystallizes in the form of slender needles united in fasciculi. It is readily dissolved by water, and less easily by alcohol. As ordinarily obtained, however, by evaporation to dryness, it is not entirely soluble in water, a portion of it being uncombined morphia. To render it soluble, all that is necessary is to add a little distilled vinegar.

The Edinburgh College gives the following mode of testing its purity: "One hundred measures of a solution of ten grains in half a fluidounce of water and five minims of acetic acid, heated near to 212° , and decomposed by a faint excess of ammonia, yield by agitation a precipitate which in 24 hours occupies 15.5 measures of the liquid."

From an eighth to a quarter of a grain may be given for a dose, and repeated, if necessary, in order to obtain the anodyne and soporific effect of the medicine. One-sixth of a grain is about equivalent to a grain of opium. It may be given in pill or solution. It is frequently employed externally, sprinkled on blistered surfaces, to obtain its effects upon the system. W.

MORPHIÆ MURIAS. *U.S.*, *Ed.* MORPHIÆ HYDROCHLORAS. *Lond.* *Muriate of Morphia.* *Hydrochlorate of Morphia.*

"Take of Morphia, in powder, *an ounce*; Distilled Water *half a pint*; Muriatic Acid *a sufficient quantity*. Mix the Morphia with the Water; then carefully drop in the Acid, constantly stirring, till the Morphia is saturated and dissolved. Evaporate the solution by means of a water-bath, so that it may crystallize upon cooling. Dry the crystals upon bibulous paper." *U.S.*

"Take of Opium, sliced, *a pound*; Crystals of Chloride of Lead *two ounces*, or *a sufficient quantity*; Purified Animal Charcoal *three ounces and a half*; Hydrochloric [Muriatic] Acid, Distilled Water, Solution of Ammonia, each, *a sufficient quantity*. Macerate the Opium, for thirty

hours, in *four pints* [Imperial measure] of Distilled Water, and bruise it; then digest it for twenty hours, and press it. Macerate the residue a second and a third time in Water, so that it may be deprived of taste, and as often bruise and press it. Mix the liquors, and evaporate them with a heat of 140° to the consistence of syrup. Then add three pints of Distilled Water, and, when all the dregs have subsided, pour off the supernatant liquor. To this add gradually two ounces of Chloride of Lead, or a sufficient quantity, previously dissolved in four pints of boiling Distilled Water, until nothing more is thrown down. Pour off the liquor, and wash the residue frequently with Distilled Water. Then evaporate the mixed liquors, as before, with a gentle heat, and set them aside to crystallize. Press the crystals in a linen cloth, then dissolve them in a pint of Distilled Water, and, having digested with an ounce and a half of Animal Charcoal, at 120° , filter the solution. Finally, having washed the charcoal, cautiously evaporate the liquors, in order to obtain pure crystals. To the liquor poured off from the crystals first separated, add a pint of water, and gradually drop in, occasionally shaking, sufficient Solution of Ammonia to precipitate all the morphia. To this, washed with Distilled Water, add Hydrochloric Acid so as to saturate it; then digest with two ounces of Animal Charcoal, and filter. Lastly, having thoroughly washed the charcoal, cautiously evaporate the liquors, so as to obtain pure crystals." *Lond.*

"Take of Opium *twenty ounces*; Water *eight pints* [Imperial measure]; Muriate of Lime [chloride of calcium] *one ounce*, or a *slight excess*. Macerate the Opium in fragments for twenty-four hours in two pints of the Water; and separate the infusion, squeezing well the residue. Repeat the maceration successively with two pints more of the Water till the whole is made use of. Concentrate the whole infusions over the vapour-bath to one pint, and add the Muriate of Lime dissolved in four fluidounces of Water. Set the whole aside to settle; pour off the liquid; wash the sediment with a little water, adding the washings to the liquid. Evaporate the liquid sufficiently in the vapour-bath for it to solidify on cooling. Subject the cooled mass to very strong pressure in a cloth; redissolve the cake in a sufficiency of warm distilled water; add a little fine powder of white marble, and filter; acidulate the filtered fluid with a very little muriatic acid; and concentrate a second time in the vapour-bath for crystallization. Subject the crystals again to very strong pressure in a cloth. Repeat the process of solution, clarification by marble and muriatic acid, concentration, and crystallization, until a snow-white mass be obtained.

"On the small scale trouble and loss are saved by decolorizing the solution of muriate of morphia by means of a little purified animal charcoal after two crystallizations. But on the large scale it is better to purify the salt by repeated crystallizations alone, and to treat all the expressed fluids, except the first, in the same way with the original solution of impure muriate of morphia. An additional quantity of salt may often be got from the first dark and resinous fluid obtained by expression, on merely allowing it to remain at rest for a few months, when a little muriate of morphia may be deposited in an impure condition.

"The opium which yields the largest quantity of precipitate by carbonate of soda, according to the formula [given in page 518], yields muriate of morphia not only in greatest proportion, but likewise with the fewest crystallizations." *Ed.*

In relation to the process of the U. S. Pharmacopœia, the remarks made upon the preparation of the sulphate of morphia are equally applicable here. (See *Morphiæ Sulphas.*) The London and Edinburgh processes are based

upon the plan, originally suggested by Wittstock, of obtaining the muriate of morphia immediately from opium without the use of alcohol. The Edinburgh process is that of Dr. Wm. Gregory, which was an improvement upon Wittstock's. The London is a modification but scarcely an improvement of Gregory's. In both processes, the meconate and a small proportion of sulphate of morphia extracted by water from opium are decomposed; in the Edinburgh, by chloride of calcium, yielding muriate of morphia in solution, and meconate and sulphate of lime as precipitates; in the London, by chloride of lead yielding muriate of morphia as in the former case in solution, but meconate and sulphate of lead as precipitates. The remaining steps of the operation consist in obtaining the muriate of morphia from the solution by evaporation and crystallization, and in freeing it from colouring impurities. For the latter purpose the Edinburgh College directs the alternate addition of marble and muriatic acid, and repeated solution, concentration, and crystallization; advising, when the process is conducted upon a small scale, the use of animal charcoal after two crystallizations. The London College spares the trouble of these repeated operations, and contents itself with the decolorizing influence of the animal charcoal. The Edinburgh College prevents waste by operating upon all the mother liquors except that separated by the first expression in the same manner as upon the original infusion of opium; the London, by precipitating with ammonia, saturating the precipitated morphia with muriatic acid, and decolorizing with animal charcoal. Points deserving of particular notice in these processes are, to obtain the original infusion of opium as concentrated as possible without leaving morphia behind, so as to shorten the period of evaporation; and, to add the chloride of lime or of lead before instead of after the concentration; as, according to Christison, a larger and purer product is obtained, in the former way, with fewer crystallizations. Dr. Christison says, in favour of Dr. Gregory's process, that the Edinburgh manufacturers, who follow it, produce a salt of unrivalled purity and cheapness. But it is much better calculated for the large laboratory of the manufacturing chemist, than for the smaller operations of the apothecary, who will probably find the U. S. process more convenient.

The muriate of morphia procured by the processes of the British Colleges always contains a portion of muriate of codeia, which, however, is scarcely sufficient to affect its operation upon the system. Dr. Christison found the proportion to vary between a 60th in the muriate prepared from good Turkey opium, a 30th in that from inferior samples of the same variety, and a 12th in that from the East Indian. This impurity may be separated by precipitating the morphia from a solution of the salt by means of ammonia; the codeia being left in solution. The salt is quite free from narcotina.

Dr. A. T. Thomson has published a process for procuring muriate of morphia which he has found considerably more productive than that of the British Colleges. After macerating the opium in water as directed by the Colleges for thirty hours, and expressing, he rubs it in a mortar with an equal weight of pure white sand, and enough water to form the mixture into a paste, which he places in a percolator, and subjects to the action of distilled water till the fluid passes without colour and taste. He then concentrates the liquors to the consistence of a thin syrup, adds diacetate of lead, dilutes the solution with twice its bulk of distilled water, allows it to stand for twenty-four hours, decants the supernatant liquid, washes the precipitate with warm water, adds the washings to the decanted solution, and concentrates to one-half. To free the liquid from any remaining acetate of

lead he adds diluted sulphuric acid in slight excess, decants the liquid from the precipitate, washes the latter, adds the washings to the solution, and boils for some minutes to drive off acetic acid. To convert the sulphate of morphia now contained in the solution into muriate, he adds a saturated solution of chloride of barium, washes the precipitate, evaporates the conjoined washings and solution to the point of crystallization, presses the crystals, dilutes and again evaporates the mother liquor so long as it affords crystals, and finally purifies the crystalline product by means of animal charcoal, and by repeated solution, evaporation, and crystallization. (*Pharm. Journ. and Transact.* i. 459.)

Muriate of morphia crystallizes in tufts of feathery acicular crystals. It is white, inodorous, bitter, soluble in 16 parts of water at 60°, and in its own weight at 212°, and soluble also in alcohol. A saturated solution in boiling water, forms a solid crystalline mass on cooling. The crystals are said to consist of one equivalent of morphia 296·35, one of muriatic acid 36·42, and six of water 54. Dr. Christison states that he constantly found the crystals, when dried at 150°, to contain 12·7 per cent. of water; and the Edinburgh College states, that the loss of weight at 212° is not above 13 per cent. The salt may be known to be a muriate by the test of nitrate of silver, and to contain morphia by the tests for that alkali.

This preparation of morphia is much used in Great Britain, but, in this country, less than either the sulphate or acetate. The dose of it, equivalent to a grain of opium, is about one-sixth of a grain.

W.

MORPHIÆ MURIATIS SOLUTIO. *Ed.* *Solution of Muriate of Morphia.*

“Take of Muriate of Morphia *one drachm and a half*; Rectified Spirit *five fluidounces*; Distilled Water *fifteen fluidounces*. Mix the Spirit and Water, and dissolve the Muriate of Morphia in the mixture with the aid of a gentle heat.” *Ed.*

The use of the alcohol is to prevent spontaneous decomposition. The solution was intended to have the strength of laudanum. Eighteen minims contain about one-sixth of a grain of the muriate, equivalent to about a grain of opium.

W.

MORPHIÆ SULPHAS. *U. S.* *Sulphate of Morphia.*

“Take of Morphia, in powder, *an ounce*; Distilled Water *half a pint*; Diluted Sulphuric Acid *a sufficient quantity*. Mix the Morphia with the Water, then carefully drop in the acid, constantly stirring till the Morphia is saturated and dissolved. Evaporate the solution by means of a water-bath, so that it may crystallize upon cooling. Dry the crystals upon bibulous paper.” *U. S.*

In this process the morphia is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphia employed contain narcotina, this will remain in the mother liquor, and will not contaminate the product. The mother liquor remaining after the first crystallization may be evaporated, so as to obtain a fresh supply of the sulphate, but if the morphia was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone farther preparation. When impure morphia is employed, the mother liquor should be mixed with alcohol, or boiled with washed animal charcoal and filtered, and then

decomposed by ammonia, which will precipitate the morphia. This may then be converted into the sulphate in the manner directed by the Pharmacopœia.

Another mode of obtaining sulphate of morphia, is to dissolve the alkali in boiling alcohol of 36° Baumé (sp. gr. 0.8428), saturate it while hot with sulphuric acid, add animal charcoal previously washed with muriatic acid, boil for a few minutes, and filter the solution, while at the boiling temperature. Upon cooling, it deposits most of the sulphate; and the remainder may be obtained by evaporating the mother liquor.

The sulphate of morphia crystallizes in beautifully white, minute, feathery crystals, which are soluble in cold water, and in twice their weight of boiling water. They contain, according to Liebig, in 100 parts, 14.29 of water, 10.33 of sulphuric acid, and 75.38 of morphia. By exposure to a heat of 248° F. they lose 9.66 parts of the water, but cannot be deprived of the remainder without decomposition. Their equivalent composition is stated to be one eq. of morphia 296.35, one of sulphuric acid 40.1, and six of water 54, of which five are water of crystallization, and may be expelled by heat. The tests for it are those for sulphuric acid and for morphia.

The dose of the sulphate of morphia is from an eighth to a quarter of a grain, which may be given in pill or solution.

Off. Prep. Liquor Morphiæ Sulphuris, U. S. W.

LIQUOR MORPHIÆ SULPHATIS. U. S. *Solution of Sulphate of Morphia.*

“Take of Sulphate of Morphia *eight grains*; Distilled Water *half a pint*. Dissolve the Sulphate of Morphia in the Water.” U. S.

Sulphate of morphia, as found in the shops, is not always entirely soluble in water. This sometimes, perhaps, arises from adulterations; but more frequently, in all probability, from the mode in which the sulphate is prepared. In the preparation of this salt, the quantity of water employed for the suspension of the morphia is sometimes insufficient to hold the resulting sulphate in solution; and the consequence is that, upon the addition of sulphuric acid, the crystallization of the sulphate takes place before the whole of the morphia has been saturated by the acid. A portion of uncombined morphia is therefore necessarily mixed with the salt; and this is probably the cause of the incomplete solubility of the sulphate of morphia alluded to. This explanation is rendered still more probable by the fact, that the addition of a little sulphuric acid usually remedies the defect and renders the whole soluble. Pure sulphate of morphia is readily and entirely soluble in water.

This solution is very convenient, by enabling the physician to prescribe a minute dose, which, in consequence of the great energy of the preparations of morphia, is very often necessary. It has the advantage that it may be kept for a very considerable length of time unchanged. The full dose for an adult is from one to two fluidrachms, containing from an eighth to a quarter of a grain of the sulphate. W.

MUCILAGINES.

Mucilages.

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U. S. Pharmacopœia, is an aqueous solution of gum or of substances closely allied to it. As used by the British Colleges it appears

to signify any bland, viscid, aqueous, vegetable solution, resembling that of gum in sensible properties. W.

MUCILAGO ACACIÆ. U. S. MUCILAGO. Ed. MUCILAGO GUMMI ARABICI. Dub. MISTURA ACACIÆ. Lond. *Mucilage of Gum Arabic.*

“Take of Gum Arabic, in powder, *four ounces*; boiling Water *half a pint*. Add the Water gradually to the Gum, rubbing them together till the mucilage is formed.” U. S.

The *London College* takes *ten ounces* of powdered gum Arabic, and *a pint* [Imperial measure] of boiling water, and proceeds as above. The *Edinburgh College* directs *nine ounces* of gum Arabic to be dissolved in *a pint* [Imp. meas.] of cold water, without heat, but with occasional stirring, and then to be strained through linen or calico. The *Dublin College* takes *four ounces* of the gum, in coarse powder, and *four fluidounces* of warm water, digests the ingredients with frequent agitation till the gum is dissolved, and strains the resulting mucilage through linen.

Straining through linen is necessary to separate the foreign substances which are often mixed with gum Arabic. This mucilage is semitransparent, almost colourless if prepared from good gum, viscid, tenacious, of a feeble peculiar odour, and nearly tasteless. If the solution of gum should be coloured, it may be rendered colourless by the addition of a concentrated solution of chlorine; and, by boiling for about half an hour so as to drive off the chlorine and muriatic acid, it may be rendered fit for use. (*Guérin.*) By keeping, mucilage becomes sour in consequence of the spontaneous generation of acetic acid; and this happens even though it be enclosed in well stopped bottles. But, according to M. Guérin, the aqueous solution of pure gum undergoes no change in vacuo. Heat in its preparation is said to favour the production of acid, in which case the *Edinburgh* formula is preferable. Mucilage is employed chiefly in the formation of pills, and for the suspension or diffusion of insoluble substances in water.

MUCILAGO AMYLI. Ed., Dub. DECOCTUM AMYLI. Lond. *Mucilage of Starch.*

“Take of Starch *four drachms*; Water *a pint* [Imperial measure]. Rub the Starch with the Water gradually added; then boil for a short time.” Lond.

The *Edinburgh College* takes *half an ounce* of starch and *a pint* [Imp. meas.] of water; the *Dublin*, *six drachms* of the former and *a pint* of the latter; both proceed according to the directions of the *London College*.

This mucilage has an opaline appearance, and gelatinous consistence, and is much used as a vehicle for laudanum and other active remedies given in the form of enema. In consequence of its demulcent properties, it may be usefully employed as an enema in irritation and inflammation of the mucous coat of the rectum and large intestines. Its unpleasant flavour, when it is prepared from ordinary starch, precludes its employment by the mouth.

Off. Prep. Enema Opii, Lond. W.

MUCILAGO TRAGACANTHÆ. U. S., Ed. MUCILAGO GUMMI TRAGACANTHÆ. Dub. *Mucilage of Tragacanth.*

“Take of Tragacanth *an ounce*; boiling Water *a pint*. Macerate the Tragacanth in the Water for twenty-four hours, occasionally stirring; then triturate it so as to render the mucilage uniform, and strain forcibly through linen.” U. S.

The *Edinburgh College* takes *two drachms* of tragacanth and *nine fluidounces* of boiling water, macerates for twenty-four hours, then triturates, and expresses through linen or calico. The *Dublin College* takes *two drachms* of tragacanth, in powder, and *eight fluidounces* of water, macerates in a covered vessel till the gum is dissolved, and then strains through linen.

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent; as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. In consequence of its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water.

OLEA DESTILLATA.

Distilled Oils.

For an account of the general properties of the volatile, essential, or distilled oils, the reader is referred to the head of *Olea Volatilia* in the first part of this work. The following are the different official directions for preparing them.

OLEA DESTILLATA. *U. S.*

“In the preparation of the Distilled Oils, put the substance from which the oil is to be extracted into a retort, or other vessel suitable for distillation, and add enough water to cover it, then distil into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it.

“In this manner prepare OIL OF ANISE, from Anise; OIL OF CARAWAY, from Caraway; OIL OF WORMSEED, from Wormseed; OIL OF FENNEL, from Fennel-seed; OIL OF PARTRIDGE-BERRY, from Partridge-berry [leaves]; OIL OF PENNYROYAL [Oleum Hedeomæ], from Pennyroyal; OIL OF JUNIPER, from Juniper [berries]; OIL OF LAVENDER, from Lavender [flowers]; OIL OF PEPPERMINT, from Peppermint; OIL OF SPEARMINT, from Spearmint; OIL OF HORSEMINT, from Horsemint; OIL OF ORIGANUM, from Origanum [Marjoram]; OIL OF PIMENTO, from Pimento; OIL OF ROSEMARY, from Rosemary [tops]; OIL OF SAVINE, from Savine; OIL OF SASSAFRAS, from Bark of Sassafras Root.” *U. S.*

OLEA DESTILLATA. *Lond.*

“OIL OF ANISE, of CHAMOMILE, of CARAWAY, of JUNIPER, of LAVENDER, of PEPPERMINT, of PENNYROYAL [Mentha Pulegium], of SPEARMINT, of ORIGANUM, of PIMENTO, of ROSEMARY, of ELDER FLOWERS.

“The fruit of Anise, Caraway, and Juniper, the flowers of Chamomile, Lavender, and Elder, the berries of Pimento, the tops of Rosemary, and the fresh herb of the other plants, are to be employed. Put any one of these into an alembic, and add sufficient Water to cover it; then distil the Oil into a large refrigeratory.” *Lond.*

VOLATILE OILS. *Ed.*

“Volatile oils are obtained chiefly from the flowers, leaves, fruits, barks,

and roots of plants, by distilling them with water, in which they have been allowed to macerate for some time. Flowers, leaves, and fruits generally yield the finest oils, and in greatest quantity, when they are used fresh. Many, however, answer equally well if they have been preserved by beating them into a pulp with about twice their weight of muriate of soda, and keeping the mixture in well-closed vessels.

"Substances yielding volatile oils must be distilled with water, the proper proportion of which varies for each article, and for the several qualities of each. In all instances, the quantity must be such as to prevent any of the material from being empyreumatized before the whole oil is carried over. In operations where the material is of pulpy consistence, other contrivances must be resorted to for the same purpose. These chiefly consist of particular modes of applying heat so as to maintain a regulated temperature not much above 212° . On the small scale heat may be thus conveniently applied by means of a bath of a strong solution of muriate of lime, or by means of an oil-bath, kept at a stationary temperature with the aid of a thermometer. On the large scale heat is often applied by means of steam under regulated pressure. In other operations it is found sufficient to hang the material within the still in a cage or bag of fine net-work; and sometimes the material is not mingled with the water at all, but is subjected to a current of steam passing through it.

"The best mode of collecting the oil is by means of the refrigeratory described in the preface [see page 772]; from which the water and oil drop together into a tall narrow vessel, provided with a lateral tube or lip near the top, and another tube rising from the bottom to about a quarter of an inch below the level of the former. It is evident that, with a receiver of this construction, the water will escape by the lower tube; while the volatile oil, as it accumulates, will be discharged by the upper one, except in the very few instances where the oil is heavier than the water.

"By attending to the general principles now explained, Volatile Oils may be readily obtained of excellent quality from the flowers of *ANTHEMIS NOBILIS*, *LAVANDULA VERA*, and *RUTA GRAVEOLENS*; from the fruit of *ANETHUM GRAVEOLENS* bruised, *CARUM CARUI* bruised, *EUGENIA PIMENTA* bruised, *FENICULUM OFFICINALE* bruised, *JUNIPERUS COMMUNIS* bruised, *PIPER CUBEBA* ground, and *PIMPINELLA ANISUM* ground; from the undeveloped dried flowers of *CARYOPHYLLUS AROMATICUS*; from the tops of *JUNIPERUS SABINA*, and *ROSMARINUS OFFICINALIS*; from the entire herb of *MENTHA PIPERITA*, *MENTHA PULEGIUM*, *MENTHA VIRIDIS*, and *ORIGANUM MAJORANA* [vulgare?]; and also from the bruised root of *SASSAFRAS OFFICINALE*." *Ed.*

OLEA ESSENTIALIA. *Dub.*

"OIL of ANISEED, of CARAWAY, of FENNEL, from the seeds dried with a medium heat; of SASSAFRAS, from the bark and wood; of JUNIPER, of PIMENTO, from the berries; of LAVENDER, from the flowers; of PEPPERMINT, of SPEARMINT, of ORIGANUM, of PENNYROYAL, of ROSEMARY, of RUE, from the leaves and flowers of the plant while in flower; of SAVINE, from the leaves.

"Put the substance, previously macerated in Water, into an alembic; then, by means of the vapour of boiling water, distil into a receiver. Separate by a proper apparatus, the Oil which floats on the surface, or sinks to the bottom, according as it is lighter or heavier than water. In distilling the seeds of Caraway and Fennel, the leaves of Peppermint, Spearmint, and Pennyroyal, and the berries of Pimento, the liquor which comes over

with the oil is to be kept for use in the manner directed under the head of Distilled Waters." *Dub.*

The substances from which the volatile oils are extracted, may be employed either in the recent or dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt, as they afford little or no oil after exsiccation. Most of the aromatic herbs also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh, and are directed in this state by the London College; although it is thought by some that, when moderately dried, they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water till they are thoroughly penetrated by this fluid; and to facilitate the action of the water, it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising, or other similar mechanical operation.

The water which is put with the subject of distillation into the alembic, answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances it readily rises with the vapour of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 212° ; and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 230° . Recourse may also be had to a bath of strong solution of chloride of calcium, or to an oil-bath the temperature of which is regulated by a thermometer, as suggested by the Edinburgh College in their general directions (see page 1047). Other oils again may be volatilized with water at a temperature below the boiling point; and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat it has been recommended to suspend the substance containing the oil in a basket, or to place it upon a perforated shelf, in the upper part of the alembic, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distil *in vacuo*. Dr. Duncan stated that the most elegant volatile oils he had ever seen were prepared in this manner by Mr. Barry, the inventor of the process.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution, when the mixed vapours are condensed; and, if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled; and there will be danger of the substance in the alembic adhering to the sides of the vessel, and thus becoming burnt. Enough water should always be added to cover the solid material, and prevent this latter accident. Dried plants require more water than those which are fresh and succulent. The whole amount of materials in the alembic should not exceed three-fourths of its capacity; as otherwise there would be danger of the liquor boiling over. The form of the alembic has a considerable influence over the quantity of water distilled, which depends more upon the extent of surface than the amount of liquid submitted to evaporation. By employing a high and narrow vessel, we may obviate the disadvantage of an excess of water. The broad shallow alembic, suitable for the distillation of alcohol and the spirituous liquors, will not answer so well in this

case. Sometimes the proportion of oil contained in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the alembic is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant till the quantity of oil exceeds its solvent power. This process is called *cobobation*.

The more volatile of the oils pass with facility along with the steam into the neck of the common still; but some which are less volatile are apt to condense in the head, and thus return into the alembic. For the distillation of the latter, a still should be employed with a large and very low head, having a rim or gutter around its internal circumference, into which the oils may be received as they condense, and thence pass into the neck. As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tube should be straight, than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, become solid at a comparatively high temperature; and that, in the distillation of these, the water employed for refrigeration should not be below 42° F.

The mixed vapours are condensed into a milky liquid, which is collected in a receiver, and after standing for some time separates into a clear solution of the oil in water, and into the oil itself, the latter floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the fluid which comes over has this milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florence receiver* may be used. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downwards. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates so long as the process continues; but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled. But as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separatory* is usually employed for this purpose. It consists of a glass funnel, bulging at the top, where it is furnished with a stopper, and prolonged at the bottom into a very narrow tube. (See figure, page 758.) The lower opening being closed, the mixed liquids are introduced, and allowed to stand till they separate. The orifice at the bottom is then opened, and the stopper at top being a little loosened so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than water, it passes out of the separatory; if lighter, it remains within. Another mode of separating the oil, is to introduce into the vessel containing the two liquids, one end of a cord of cotton, the other end hanging out and terminating in a suitable receptacle beneath the level of that im-

mersed in the liquid. The oil at top passes through the cord, and may thus be wholly removed. The last drops may be collected by pressing the cord between the fingers.

The water saturated with oil should be preserved for future distillations, as it can now dissolve no more of the oil, and will therefore yield a larger product.

When first procured, the oil has a disagreeable empyreumatic odour, from which it may be freed by allowing it to stand for some days in vessels loosely covered with paper. It should then be introduced into small opaque bottles, which should be well stopped, so as to exclude the air. When altered by exposure to air, the oils may sometimes be nearly or quite restored to their original appearance and quality by agitation with a little recently heated animal charcoal; and the same method may be employed for freeing oils from adhering water.

The volatile oils have the medical properties of the plants from which they are derived; and as their remedial application has been mentioned under the heads of these plants respectively, it will be unnecessary to treat of it in this place. They may be administered dropped on a lump of sugar; or triturated with at least ten times their weight of sugar, forming an *oleo-saccharum*, and then dissolved in water; or made into an emulsion with water, sugar, and gum Arabic. They are frequently kept dissolved in alcohol under the name of *essences*. W.

OLEUM ANETHI. *Ed. Oil of Dill.*

The fruit of dill yields about 3·5 per cent. of volatile oil. This is of a pale yellow colour, with the odour of the fruit, and a hot sweetish taste. Its specific gravity is stated at 0·881. It is employed to prepare dill water, and may be given as a carminative in the dose of from three to four drops; but it is little used in this country. W.

OLEUM ANISI. *U.S., Lond., Ed., Dub. Oil of Anise.*

The product of oil from aniseed is variously stated from 1·56 to 3·12 per cent. The oil employed in this country is almost all imported. It is colourless or yellowish, with the peculiar odour and taste of the seed. At 50° it crystallizes in flat tables, and does not melt under 62°. Its sp. gr. increases with age, and is variously given from 0·9768 to 0·9903. It is soluble in all proportions in alcohol of 0·806; but alcohol of 0·840 dissolves at 77° only 42 per cent. It consists of two oils, one solid at ordinary temperatures and heavier than water (*stearoptene*), the other liquid and more volatile (*eleoptene*), both of which are said to have the same atomic constitution, and to consist of carbon, hydrogen, and oxygen ($C_{10}H_6O$). It absorbs oxygen from the air and becomes less disposed to concrete. Oil of anise is said to be sometimes adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odour. The dose of the oil is from five to fifteen drops. Its comparative mildness adapts it to infantile cases. The *oil of star aniseed* (*oleum badiani*), which resembles it in flavour, is frequently substituted for it in this country.

Off. Prep. Syrupus Sarsaparillæ Compositus, *U.S.*; Tinctura Opii Ammoniata, *Ed.*; Tinct. Opii Camphorata, *U.S., Lond., Ed., Dub.*; Trochisci Glycyrrhizæ et Opii, *U.S.* W.

OLEUM ANTHEMIDIS. *Lond., Ed. Oil of Chamomile.*

This is never prepared, and little used, in this country. Baumé obtained thirteen drachms of the oil from eighty-two pounds of the flowers. It has

the peculiar smell of chamomile, with a pungent somewhat aromatic taste. When recently distilled it is of a sky-blue colour, which changes to yellow or brownish on exposure. The sp. gr. of the English oil is said to be 0.9083. It has sometimes been used in spasm of the stomach, and as an adjunct to purgative medicines. The dose is from five to fifteen drops.

On the continent of Europe, an oil extracted from the *Matricaria Chamomilla* is employed under the name of oil of chamomile. It is dark blue, thick, and nearly opaque, becoming brown and unctuous by time. It has the odour of the plant from which it is derived, and an aromatic taste. W.

OLEUM CARI. U.S. OLEUM CARUI. *Lond., Ed., Dub.* Oil of Caraway.

This oil is prepared to a considerable extent by our distillers. The fresh fruit yields on an average about 4.7 per cent. (Recluz); but the product is very variable. The oil of caraway is somewhat viscid, of a pale yellow colour becoming brownish by age, with the odour of the fruit, and an aromatic acrid taste. Its sp. gr. is 0.946 according to Baumé, 0.931 according to Brande. Its constituents are carbon, hydrogen, and oxygen. It is much used to impart flavour to medicines, and to correct their nauseating and griping effects. The dose is from one to ten drops.

Off. Prep. Confectio Scammonii, *Lond., Dub.*; Electuarium Sennæ, *Dub.*; Pilulæ Aloës Compositæ, *Lond., Dub.*; Pilulæ Rhei Compositæ, *Lond.* W.

OLEUM CHENOPODII. U.S. Oil of Wormseed.

This oil is peculiar to the United States. It is of a light yellow colour when recently distilled, but becomes deeper yellow, and even brownish by age. It has in a high degree the peculiar flavour of the plant. Its sp. gr. is 0.908. It is used as an anthelmintic, in the dose of from four to eight drops for a child, repeated morning and evening for three or four days, and then followed by a brisk cathartic. W.

OLEUM COPAIBÆ. *Ed.* Oil of Copaiba.

"Take of Copaiva one ounce; Water one pint and a half [Imperial measure]. Distil, preserving the water; when most of the water has passed over, heat it, return it into the still, and resume the distillation; repeat this process so long as a sensible quantity of oil passes over with the water." *Ed.*

This oil is sufficiently described under Copaiba, page 271.

OLEUM FÆNICULI. U.S., *Ed.* OLEUM FÆNICULI DULCIS. *Dub.* Oil of Fennel.

Fennel seeds yield about 2.5 per cent. of oil. That used in this country is imported. It is colourless or yellowish, with the odour and taste of the seeds. Its sp. gr. is 0.997. It congeals below 50° into a crystalline mass, separable by pressure into a solid and liquid oil (*stearoptene* and *eleoptene*), the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. As found in the shops, therefore, the oil of fennel is not uniform; and Dr. Montgomery found that a specimen which he examined did not congeal at 22°. It consists of carbon, hydrogen, and oxygen; its formula being, according to Blanchet and Sill, $C_{15}H_{20}O_2$. The dose is from five to fifteen drops.

Off. Prep. Aqua Fœniculi, U.S. W.

OLEUM GAULTHERIÆ. U.S. Oil of Partridge-Berry.

This oil is known only in the United States, and is prepared chiefly in

New Jersey. It is directed by the Pharmacopœia to be prepared from the leaves of the *Gaultheria procumbens*; but the whole plant is usually employed. It has been supposed to exist also in the bark of the *Betula lenta*, the root of the *Polygala paucifolia*, and the roots and stems of the *Spiræa ulmaria*, *Spiræa lobata*, and *Gaultheria hispidula*, which have its peculiar flavour. The oil of partridge-berry when freshly distilled is nearly colourless, but as found in the shops has a brownish-yellow or reddish colour. It is of a sweetish, slightly pungent, peculiar taste, and a very agreeable characteristic odour, by which it may be readily distinguished from all other officinal oils. It is the heaviest of the known essential oils, having the sp. gr. 1.173. Its boiling point is 412°. (*Am. Journ. of Pharm.* iii. 199, and xiv. 213.) Its unusual weight affords a convenient test of its purity. Mr. Wm. Procter, Jun., of Philadelphia, has shown it to possess acid properties, and to be closely analogous to *saliculous* acid, one of the results of the decomposition of salicin by sulphuric acid and bichromate of potassa, and an ingredient in the oil of *Spiræa ulmaria*. (See *Salix*, page 623.) Thus, it combines with the alkalies, earths, and metallic oxides; forms compounds with chlorine, bromine, &c., in which an equivalent of hydrogen is replaced by an equivalent of one of these bodies respectively; and, when treated with potassa in excess, gives out hydrogen, and is converted into another acid (*saliculinic acid*), in which oxygen appears to have taken the place of the hydrogen liberated. It has, moreover, the density of saliculous acid, and like it colours the sesquisalts of iron purple. But there are several points of difference sufficient to prevent the admission of the absolute identity of the two substances. The oil of spiræa differs from that of gaultheria in containing another volatile oil besides the saliculous acid. (*Am. Journ. of Pharm.* xiv. 211.) Oil of gaultheria is used chiefly on account of its pleasant flavour, to cover the taste of other medicines.

Off. Prep. Syrupus Sarsaparillæ Compositus, U.S.

W.

OLEUM HEDEOMÆ. U.S. Oil of Pennyroyal.

This, though analogous in properties to the oil of European pennyroyal, is derived from a distinct plant—the *Hedeoma pulegioides*—peculiar to North America. It has a light yellow colour, with the odour and taste of the herb. Its sp. gr. is 0.948. It may be used as a remedy in flatulent colic and sick stomach, to correct the operation of nauseating or griping medicines, and to impart flavour to mixtures. The dose is from two to ten drops.

W.

OLEUM JUNIPERI. U.S., Lond., Ed., Dub. Oil of Juniper.

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained one per cent. The highest quantity given in the table of Recluz is 2.34, the lowest 0.31 per cent. The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe. It is colourless, or of a light greenish-yellow, with a terebinthinate odour, and a hot acrid taste. Its sp. gr. is 0.911. It is not very soluble in alcohol. According to Blanchet, it contains two isomeric oils, of which one is colourless, and the other coloured and less volatile. It is, when pure, a hydrocarbon, and is said to have the same composition as oil of turpentine ($C_{10}H_8$); but it does not form a solid compound with muriatic acid. (*Journ. de Pharm.* xxvi. 80.) The oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture, which is considerably less than that of the unadulterated oil of juniper.

This oil is stimulant, carminative, and diuretic; and may be employed advantageously in debilitated dropsical cases, in connexion with other medicines, especially digitalis. It is this oil which imparts to Holland gin its peculiar flavour and diuretic power. The dose is from five to fifteen drops two or three times a day, and may be considerably increased. W.

OLEUM LAVANDULÆ. *U. S., Lond., Ed., Dub.* Oil of Lavender.

Dried lavender flowers yield from 1 to 1.5 per cent. of a very fluid, lemon-yellow oil, having the fragrance of the flowers, and an aromatic, burning taste. That met with in commerce has the sp. gr. 0.898 at 68° F., which is reduced to 0.877 by rectification. (*Berzelius.*) According to Brande, the sp. gr. of the oil obtained from the whole herb is 0.9206. Alcohol of 0.830 dissolves the oil of lavender in all proportions; that of 0.887, only 42 per cent. (*Berzelius.*) Proust states that, when allowed to stand in imperfectly stopped bottles, it lets fall a crystalline deposit (*stearoptene*), which often amounts to one-fourth of the weight of the oil. It is said that the portion of oil first distilled is most agreeably fragrant, and is often kept separate, and sold at a higher price. The oil of lavender is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of nervous languor and headache. The dose is from one to five drops.

The oil of spike is procured from the broad-leaved variety of lavender which grows wild in Europe, the *Lavandula Spica* of De Candolle. Its odour is less fragrant than that of the common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is much used by artists in the preparation of varnishes. *Off. Prep.* Tinctura Ammoniae Composita, *Lond.* W.

OLEUM MENTHÆ PIPERITÆ. *U. S., Lond., Ed.* **OLEUM MENTHÆ PIPERITIDIS.** *Dub.* Oil of Peppermint.

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. The product is generally less than one per cent. This oil is largely distilled in the United States. It is of a greenish-yellow colour or nearly colourless, but becomes reddish by age. Its odour is strong and aromatic; its taste, warm, camphorous, and very pungent, but succeeded, when air is admitted into the mouth, by a sense of coolness. Its sp. gr. is stated differently from 0.902 to 0.920; its boiling point at 365°. Upon long standing it deposits a *stearoptene*, which, according to Kane, has the same composition as the oil, viz., $C_{21}H_{20}O_2$. *Berzelius* states that at 8° below zero the oil deposits small capillary crystals.

Oil of peppermint is stimulating and carminative, and is much used in flatulence, nausea, spasmodic pains of the stomach and bowels, and as a corrigent or adjuvant of other medicines. The dose is from one to three drops, and is most conveniently given rubbed up with sugar and then dissolved in water. The oil is also very frequently employed in the form of *essence of peppermint*, prepared by dissolving two fluidounces in a pint of alcohol, and given upon sugar in the dose of ten or twenty drops. This is now official under the name of *Tinctura Olei Menthæ Piperitæ*.

Off. Prep. Aqua Menthæ Piperitæ, *U. S., Lond.*; Pilulæ Rhei Compositæ, *U. S., Ed.*; Spiritus Menthæ Piperitæ, *Lond., Dub.*; Tinctura Olei Menthæ Piperitæ, *U. S.*; Trochisci Menthæ Piperitæ, *U. S.* W.

OLEUM MENTHÆ PULEGII. *Lond.* OLEUM PULEGII. *Ed., Dub.* *Oil of European Pennyroyal.*

About 1 part of this oil on an average is obtained from 100 parts of the plant. When freshly distilled it is yellowish, but becomes reddish by age. Its sp. gr. is stated differently from 0.925 to 0.978. It possesses medical properties similar to those of the oil of peppermint; but is seldom used in this country. The dose is from one to five drops.

Off. Prep. Aqua Menthæ Pulegii, *Lond., Dub.*; Spiritus Menthæ Pulegii, *Lond., Dub.* W.

OLEUM MENTHÆ VIRIDIS. *U. S., Lond., Ed., Dub.* *Oil of Spearmint.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country. It is pale yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany colour. Its flavour is analogous to that of the oil of peppermint, but is less agreeable and less pungent. Its sp. gr. is stated differently from 0.914 to 0.975; its boiling point, at 320°. Kane gives the formula $C_{35}H_{28}O$, as representing its composition. It is used for the same purposes as the oil of peppermint, in the dose of from two to five drops. An *essence of spearmint* is prepared by dissolving two fluidounces of the oil in a pint of alcohol, and may be given in the quantity of from twenty to forty drops, upon a lump of sugar. This was introduced among the official tinctures in the last edition of the U. S. Pharmacopœia.

Off. Prep. Aqua Menthæ Viridis, *U. S., Lond., Dub.*; Infusum Menthæ Compositum, *Dub.*; Spiritus Menthæ Viridis, *Lond., Dub.*; Tinctura Olei Menthæ Viridis, *U. S.* W.

OLEUM MONARDÆ. *U. S.* *Oil of Horsemint.*

This is prepared by our distillers from the fresh herb of the *Monarda punctata*. It has a reddish-amber colour, a fragrant odour, and a warm, very pungent taste. Applied to the skin it acts as a powerful rubefacient, quickly producing heat, pain, redness, and even vesication. This property of the oil was made known to the profession by Dr. Atlee, formerly of Philadelphia, who employed it externally with advantage in low forms of typhus fever, cholera infantum, chronic rheumatism, and other affections in which rubefacients are indicated. In ordinary cases it should be diluted before being applied. It may be given internally as a stimulant and carminative, in the dose of two or three drops mixed with sugar and water. W.

OLEUM ORIGANI. *U. S., Lond., Ed., Dub.* *Oil of Origanum.*

This is obtained from the common marjoram, *Origanum vulgare*, and is frequently called *oil of marjoram*. The plant varies exceedingly in the proportion which it affords. The mean product may be stated at from four to six parts from a thousand. The recent oil, when properly prepared, is of a yellow colour; but if too much heat is used in the distillation, it is said to be reddish, and it acquires the same tint by age. It may be obtained colourless by rectification. It has the odour of the plant, and a hot acrid taste. Kane gives its sp. gr. 0.867, its boiling point 354°, and its composition $C_{50}H_{40}O$. According to Lewis, its sp. gr. is 0.940, according to Brande 0.909. It is sometimes used as an external irritant, and to allay the pain of toothache, by being introduced, on lint or cotton, into the cavity of a carious tooth. It is not employed internally.

It can scarcely be doubted that the oil directed by the Edinburgh College from the *Origanum Majorana*, or *sweet marjoram*, was intended for that of the *O. vulgare*; as the latter plant is indicated, under the name of *Origanum*, in the Materia Medica list of the College, where the former is not mentioned; and the oil is referred to in the Index of the Pharmacopœia with the title of *Oleum Origani*. The oil of *sweet marjoram* is obtained from the plant by distillation, in the quantity of from 2·5 to 6 parts from 1000. It is of a lemon-yellow colour, light, and camphorous, and is said upon long standing to deposit a substance resembling camphor. It is not used in this country.

Off. Prep. Linimentum Saponis Camphoratum, *U. S.*

W.

OLEUM PIMENTÆ. *U. S., Lond., Ed., Dub.* Oil of Pimento.

The berries yield from 1 to more than 4 per cent. of oil, which, as found in the shops, has a brownish-red colour, and the odour and taste of pimento, though warmer and more pungent. It is said, when freshly distilled, to be colourless or yellowish. Nitric acid reddens it. Bonastre states that it combines with salifiable bases like the oil of cloves. Its sp. gr. has been stated at 1·021, but varies. It consists, like the oil of cloves, of two distinct oils, a lighter and heavier, the former of which comes over first in distillation. They may be separated by distilling the oil with caustic potassa. The light oil comes over, and the heavy remains combined with the potassa. The latter may be obtained by distilling the residue with sulphuric acid. The light oil is lighter than water, and is a pure hydrocarbon. The heavy has the acid property of forming crystalline compounds with the alkalies. The two are closely analogous with the light and heavy oil of cloves. (*Pereira.*) The oil of pimento may be given for the same purposes with the other aromatic stimulant oils. The dose is from three to six drops.

Off. Prep. Aqua Pimentæ, *Lond.*; Emplastrum Aromaticum, *Dub.* W.

OLEUM ROSMARINI. *U. S., Lond., Ed.* OLEUM RORISMARINI. *Dub.* Oil of Rosemary.

The fresh leaves of rosemary yield, according to Baumé, 0·26 per cent. of oil; but the product is stated much higher by other authors. According to Brande, a pound of the fresh herb yields about a drachm of the oil, which is about one per cent. This oil is colourless, with an odour similar to that of the plant, though less agreeable. Its sp. gr. is 0·911, but is reduced to 0·8886 by rectification. It is soluble in all proportions in alcohol of 0·830; but requires for solution at 64°, forty parts of alcohol of the sp. gr. 0·887. (*Berzelius.*) Kane gives its sp. gr. 0·897, its boiling point 365°, and its composition $C_{45}H_{38}O_2$. Kept in bottles imperfectly stopped, it deposits a *stearoptene* analogous to camphor, and sometimes amounting, according to Proust, to one-tenth of the oil. Bucholz states that it affords camphor when digested with from one-half its weight to an equal weight of potassa, and distilled. It is said to be sometimes adulterated with the oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol. The oil of rosemary is dissolved, and that of turpentine left. This oil is possessed of stimulant properties, but is employed chiefly as an ingredient of rubefacient liniments. The dose is from three to six drops.

Off. Prep. Linimentum Opii, *Ed.*; Linimentum Saponis Camphoratum, *U. S., Ed.*; Spiritus Ammoniæ Aromaticus, *Ed.*; Spiritus Rosmarini, *U. S., Lond., Dub.*; Tinctura Saponis Camphorata, *U. S., Ed.*

W.

OLEUM RUTÆ. *Ed., Dub. Oil of Rue.*

Rue yields a very small proportion of a yellow or greenish oil, which becomes brown with age. It has the strong unpleasant odour of the plant, and an acrid taste. Kane gives its sp. gr. 0.837, its boiling point 446° , and its composition $C_{28}H_{38}O_3$. It is stimulant and supposed to be antispasmodic, and has been given in hysteria, convulsions, and amenorrhœa. The dose is from two to five drops. W.

OLEUM SABINÆ. *U. S., Ed., Dub. Oil of Savine.*

The statements in relation to the proportion of volatile oil obtained from savine vary exceedingly. While according to Hoffmann and Murray the leaves afford about 16 per cent.; others state the product at considerably less than one per cent. The highest percentage in Recluz's table, next to Hoffmann's is about 1.7, in Christison's table 2.5. (Dispensatory.) The oil is nearly colourless or yellow, limpid, strongly odorous, and of a bitterish, extremely acrid taste. Kane gives its sp. gr. 0.915, its boiling point 315° , and its composition $C_{10}H_8$, equivalent to that of oil of turpentine. The oil of savine is stimulant, emmenagogue, and actively rubefacient; and may be given for the same purposes as the plant in substance. It has been much employed empirically in amenorrhœa, and with a view to produce abortion, and in some instances with fatal effects. The dose is from two to five drops. W.

OLEUM SAMBUCCI. *Lond. Oil of Elder Flowers.*

Elder flowers yield but a very small proportion of volatile oil, which is of a butyraceous consistence when cold, and scarcely deserves a place in the Pharmacopœia.

Off. Prep. Aqua Sambuci, *Lond.*

W.

OLEUM SASSAFRAS. *U. S., Ed., Dub. Oil of Sassafras.*

The proportion of oil yielded by the root of sassafras is variously stated from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U. S. Pharmacopœia, would afford a larger quantity. The oil is of a yellow colour, becoming reddish by age. It has the fragrant odour of sassafras, with a warm pungent aromatic taste. It is among the heaviest of the volatile oils, having the sp. gr. 1.094. According to Bonastre, it separates, by agitation with water, into two oils, one lighter, the other heavier than water. Berzelius states that the first is often nothing more than oil of turpentine existing as an adulteration in the oil of sassafras. Nitric acid colours it red, and fuming nitric acid inflames it more readily than most other oils. It has the useful property of dissolving caoutchouc. When kept for a long time it deposits transparent crystals, having the same odour as the liquid oil. It is stimulant, carminative, and supposed to be diaphoretic; and may be employed for the same purposes with the bark from which it is derived. The dose is from two to ten drops.

Off. Prep. Syrupus Sarsaparillæ Compositus, *U. S.*

W.

OLEUM SUCCINI. *U. S., Dub. Oil of Amber.*

“Take of Amber, in powder, *any quantity*. Put the Amber, previously mixed with an equal weight of sand, into a glass retort, which is to be only half filled; then distil, by means of a sand-bath, with a gradually increasing heat, an acid liquor, an oil, and a concrete acid impregnated with oil. Separate the oil from the other matters, and keep it in well stopped bottles.” *U. S.*

The unrectified oil of amber is not among the preparations directed by

the *London College*. The *Dublin College* obtains it by the same process by which succinic acid is prepared. (See *Acidum Succinicum*.)

The amber in this process undergoes decomposition, and affords, among other products, an empyreumatic oil which floats in the receiver upon the surface of an acid liquor. The heat requisite for the complete decomposition of the amber cannot be supported by a glass retort; and in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware retort, which may be placed immediately upon the fire. The sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark coloured liquid, of a peculiar strong empyreumatic odour. In this state it is occasionally employed as a liniment; but for internal use it should be rectified. It is said that the scrapings of *copal* and the resin *dammar* are often substituted for amber, and yield an oil scarcely distinguishable from the genuine. (*Pereira's Mat. Med.*)

Off. Prep. Oleum Succini Rectificatum, *U. S., Dub.*

W.

OLEUM SUCCINI RECTIFICATUM. *U. S., Dub.* OLEUM SUCCINI. *Lond. Rectified Oil of Amber.*

"Take of Oil of Amber *a pint*; Water *six pints*. Mix them in a glass retort, and distil until four pints of the Water shall have passed with the oil into the receiver; then separate the Oil from the Water, and keep it in well stopped bottles." *U. S.*

The *Dublin College* employs *a pound* of oil of amber and *six pints* of water; distils until two-thirds of the water have passed into the receiver; and then separates the oil.

"Put Amber into an alembic, and distil from a sand-bath, with a heat gradually increased, an Acid Liquor, an Oil, and a Salt contaminated with oil; then distil the Oil a second and third time." *Lond.*

By successive distillations the oil of amber is rendered thinner and more limpid, till at length it is obtained colourless. The first portions which distil are less coloured than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled, as directed in the processes of the *U. S.* and *Dublin Pharmacopœias*. As usually found in the shops, the rectified oil is of a light yellowish-brown or amber colour. When quite pure it is colourless, as fluid as alcohol, of the sp. gr. 0.758 at 75°, and boils at 186°. It has a strong, peculiar, unpleasant odour, and a hot, acrid taste. It imparts these properties in some degree to water without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0.847 at 55°, in five parts of the sp. gr. 0.825, and in all proportions in absolute alcohol. The fixed oils unite with it. On exposure to the light and air, it slowly changes in colour and consistence, becoming ultimately black and solid.

Medical Properties and Uses. Rectified oil of amber is stimulant and antispasmodic; and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in amenorrhœa, and in various spasmodic and convulsive affections, as tetanus, epilepsy, hysteria, whooping cough, and infantile convulsions from intestinal irritation, &c. The dose is from five to fifteen drops, diffused in some aromatic water by means of sugar and gum Arabic. Externally applied, the oil is rubefacient, and is considerably employed as a liniment in chronic rheumatism and palsy, and in certain spasmodic disorders, as whooping cough and infantile convulsions.

In the latter affection it should be rubbed along the spine, and was highly recommended by the late Dr. Parrish, mixed with an equal measure of laudanum, and diluted with three or four parts of olive oil and of brandy.

Off. Prep. Tincturæ Ammoniac Composita, *Lond.* W.

OLEUM TEREBINTHINÆ PURIFICATUM. *Lond., Ed.*

OLEUM TEREBINTHINÆ RECTIFICATUM. *Dub. Purified Oil of Turpentine.*

“Take of Oil of Turpentine *a pint*; Water *four pints*. Carefully distil the Oil.” *Lond.*

“Take of Oil of Turpentine *one pint*; Water *four pints*. Distil as long as Oil comes over with the Water.” *Ed.*

“Take of Oil of Turpentine *two pints*; Water *four pints*. Distil a pint and a half of the Oil.” *Dub.*

Oil of turpentine becomes impure by exposure, in consequence of the absorption of oxygen and the production of resin. From this it may be freed by distillation, as above directed, or by the agency of alcohol. (See *Oleum Terebinthinæ*.) The process for distilling it is attended with some inconvenience, in consequence of the great inflammability of the vapour, and its rapid formation, which causes the liquid to boil over. In this country, the apothecary can almost always purchase the oil sufficiently pure for medical use without the necessity of rectifying it. The presence of a small proportion of resin does not interfere with its efficiency as a medicine.

W.

PILULÆ.

Pills.

These are small globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and do not require to be given in large doses. Deliquescent substances should not be made into pills, and those which are efflorescent should be previously deprived of their water of crystallization. Care should also be taken not to combine materials, the mutual reaction of which may result in a change of form.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins; and the addition of a little water to the former, and a few drops of spirit to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as crumb of bread, wheat flour, starch, and powdered gum Arabic. Powders must be mixed with soft solid bodies, as extracts, confections, soap, &c., or with tenacious liquids, as syrup, molasses, honey, or mucilage. Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used; but pills made with it are apt when kept to become hard and of difficult solubility in the liquors of the stomach, and if metallic substances are mixed with it, the mass does not work well. A mixture of syrup and powdered gum Arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Conserve of roses and molasses are among the best excipients, when the pills are to be long kept. For the same purpose of keeping the pill soft, a small portion of some fixed oil or

deliquescent salt has been recommended as an addition to the mass. Many powders require only the addition of water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with this liquid. Care should always be taken, that the matter added be not incompatible with the main ingredients of the pill.

The materials should be accurately mixed together, and beat in a mortar till formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric liquors. As pills often become very hard by time, it is convenient, in some instances, to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in bladders, putting it in covered pots, and occasionally moistening it as it becomes dry.

The mass, having been duly prepared, is made into pills by rolling it with a spatula into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or more accurately by a machine made for the purpose. The pills receive a spherical form by being rolled between the fingers. In order to prevent their adhesion to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose, carbonate of magnesia, starch, or powdered liquorice root may be used. Carbonate of magnesia is sometimes incompatible with one of the ingredients of the pills, starch is almost too light, and liquorice root will, as a general rule, be found the best. The powder of *lycopodium* is much employed on the continent of Europe; and it was formerly the custom to give the pill a coating of gold or silver leaf.

It has recently been proposed by M. Garot to cover pills with gelatin, which answers the purpose of concealing their taste, without interfering with their solubility in the stomach. He dips each pill, sustained on the point of a pin, into melted gelatin, withdraws it with a rotary motion, then fixes the pin in a paste so as to allow the coating to dry in the air, and having prepared about fifty pills in this way, proceeds to complete the operation by holding the pin in the flame of a taper so as to melt the gelatin near its point, and then withdrawing it from the pill so as to close up the orifice. The purest glue should be selected for this purpose, melted with the addition of two or three drachms of water to an ounce of the glue, and kept in the liquid state by means of a salt-bath. (See *Amer. Journ. of Pharm.* x. 229.)

Pills which are to be long kept should be put into glass bottles with accurately fitting stoppers, so as to prevent the escape of moisture.

Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills; yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will generally be found convenient by the apothecary to keep a portion of the mass undivided.

W.

PILULÆ ALOËS. U. S., Ed. *Aloetic Pills.*

“Take of Aloes, in powder, Soap, each, *an ounce*. Beat them with water so as to form a mass, to be divided into two hundred and forty pills.” U. S.

The *Edinburgh College* directs *equal quantities* of Socotrine or East India aloes, and Castile soap to be beat with conserve of red roses into a mass fit for forming pills.

The soap, in this formula, not only serves to impart a proper pilular consistence to the aloes, but is thought to qualify its operation and diminish its liability to irritate the rectum. Five pills, containing ten grains of aloes, may be given with a view to their purgative effect; but the preparation is usually employed as a laxative in cases of habitual costiveness, in the quantity of one, two, or three pills, taken before breakfast, before dinner, or at bedtime. W.

PILULÆ ALOËS COMPOSITÆ. *Lond., Dub. Compound Pills of Aloes.*

"Take of Aloes [*Hepatic Aloes, Dub.*], in powder, *an ounce*; Extract of Gentian *half an ounce*; Oil of Caraway *forty minims*; Syrup *a sufficient quantity*. Beat them together, till they are thoroughly incorporated." *Lond., Dub.*

A reaction takes place between the aloes and extract of gentian when rubbed together, which renders the mass so soft as sometimes to require the addition of a light powder. The use of syrup is therefore unnecessary and improper. This combination is well adapted as a laxative to the costiveness of sedentary and dyspeptic persons. The dose is from five to twenty grains, according to the degree of effect desired.* W.

PILULÆ ALOËS ET ASSAFÆTIDÆ. *U.S., Ed. Pills of Aloes and Assafetida.*

"Take of Aloes, in powder, Assafetida, Soap, each, *half an ounce*. Beat them with water so as to form a mass, to be divided into one hundred and eighty pills. *U.S.*

The *Edinburgh College* takes equal parts of Socotrine or East India aloes, assafetida, and Castile soap, and beats them into a mass with conserve of red roses.

These pills are peculiarly adapted, by the stimulant and carminative properties of the assafetida, to cases of costiveness attended with flatulence and debility of the digestive organs. Each pill contains about four grains of the mass. From two to five may be given for a dose. W.

PILULÆ ALOËS ET FERRI. *Ed. Pills of Aloes and Iron.*

"Take of Sulphate of Iron *three parts*; Barbadoes Aloes *two parts*; Aromatic Powder *six parts*; Conserve of Red Roses *eight parts*. Pulverize

* The following is the formula for the aloetic pills usually called *dinner pills*, or *Lady Webster's pills*. They are the *pilulæ stomachicæ* of the fifth edition of the Paris Codex, A. D. 1758. Take of the best Aloes six drachms; Mastich and Red Roses, each, two drachms; Syrup of Wormwood sufficient to form a mass, to be divided into pills of three grains each. Common syrup may be substituted for the syrup of wormwood. One or two of these pills taken shortly before a meal, will usually produce one free evacuation.

The Philadelphia College of Pharmacy has adopted formulæ for the compound aloetic preparations commonly called *Hooper's* and *Anderson's pills*, of which the following are copies.

"*Hooper's female pills.* R Aloës Barbadosensis \mathfrak{z} viiij., Ferri Sulphatis Exsiccati \mathfrak{z} ij., \mathfrak{z} iss., vel Ferri Sulphatis Crystal. \mathfrak{z} iv., Extracti Hellebori \mathfrak{z} ij., Myrrhæ \mathfrak{z} ij., Saponis \mathfrak{z} ij., Cannellæ in pulv. tritæ \mathfrak{z} j., Zingiberis in pulv. trit. \mathfrak{z} j.—Beat them well together into a mass with water, and divide into pills, each containing two and a half grains." *Journ. of the Phil. Col. of Pharm.* v. 25.

"*Anderson's Scots' pills.* R Aloës Barbadosensis \mathfrak{z} xxiv., Saponis \mathfrak{z} iv., Colocynthis \mathfrak{z} j., Gambogiæ \mathfrak{z} j., Olei Anisi \mathfrak{f} ss. Let the aloes, colocynth, and gamboge be reduced to a very fine powder; then beat them and the soap with water into a mass, of a proper consistence to divide into pills, each containing three grains." *Ibid.*

the Aloes and Sulphate of Iron separately; mix the whole ingredients; and beat them into a proper mass; which is to be divided into five grain pills." *Ed.*

It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished, by combination with the sulphate of iron. (*Christison's Dispensatory*.) This combination is useful in constipation with debility of stomach, especially when attended with amenorrhœa. The dose is from one to three pills. *W.*

PILULÆ ALOËS ET MYRRHÆ. U.S., *Ed.* PILULÆ ALOËS CUM MYRRHÆ. *Lond., Dub. Pills of Aloes and Myrrh.*

"Take of Aloes, in powder, *two ounces*; Myrrh, in powder, *an ounce*; Saffron *half an ounce*; Syrup *a sufficient quantity*. Beat the whole together so as to form a mass, to be divided into four hundred and eighty pills." *U. S.*

The processes of the *London* and *Dublin Colleges* differ from the above only in directing a double proportion of saffron, in the specification of hepatic aloes by the latter, and in not dividing the mass. The *Edinburgh College* takes *four parts* of Socotrine or East India aloes, *two parts* of myrrh, and *one part* of saffron; and beats them with conserve of red roses.

This composition has been long in use, under the name of *Rufus's pills*. It is employed as a warm stimulant cathartic in debilitated states of the system, attended with constipation, and retention or suppression of the menses. From three to six pills, or from ten to twenty grains of the mass may be given for a dose. *W.*

PILULÆ ASSAFETIDÆ. U.S. *Assafetida Pills.*

"Take of Assafetida *an ounce and a half*; Soap *half an ounce*. Beat them with water so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

Each of these pills contains three grains of the gum-resin. They are a very convenient form for administering assafetida, the unpleasant odour and taste of which render it very offensive in the liquid state. *W.*

PILULÆ CALOMELANOS COMPOSITÆ. *Ed., Dub.* PILULÆ HYDRARGYRI CHLORIDI COMPOSITÆ. *Lond. Compound Calomel Pills. Compound Pills of Chloride of Mercury.*

"Take of Chloride of Mercury [Calomel], Oxysulphuret of Antimony, each, *two drachms*; Guaiacum Resin, in powder, *half an ounce*; Molasses *two drachms*. Rub the Chloride of Mercury with the Oxysulphuret of Antimony, then with the Guaiacum Resin and Molasses, so that they may be incorporated." *Lond.*

The *Edinburgh College* takes of calomel and golden sulphuret of antimony, each, *one part*; guaiac, in fine powder, and treacle, each, *two parts*; mixes the solids in fine powder, then the treacle, and beats the whole into a mass, to be divided into six grain pills. The *Dublin College* agrees with the *London*, employing half the quantity of the active ingredients, and a sufficient quantity of molasses.

We prefer the title "compound calomel pills" of the *Edinburgh* and *Dublin Pharmacopœias*; as, though not scientific, it is not, like the *London* name, liable to be confounded with that of corrosive sublimate. The antimonial employed by the two Colleges is the same, though under different names, and is identical with the *U. S.* precipitated sulphuret. According to Vogel, a reaction takes place between the calomel and sulphuret of antimony, resulting in the production of chloride of antimony and sulphuret of

mercury. (*Annal. der Pharm.* xxviii. 236.) The preparation was originally introduced to the notice of the profession by Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's Pills*. The combination is well adapted to the treatment of chronic rheumatism, and of scaly and other eruptive diseases of the skin, especially when accompanied with a syphilitic taint. Four grains of the mass contain about one grain of calomel. From three to six grains or more may be given morning and evening. W.

PILULÆ CALOMELANOS ET OPII. *Ed. Pills of Calomel and Opium.*

"Take of Calomel *three parts*; Opium *one part*; Conserve of Red Roses *a sufficiency*. Beat them into a proper mass, which is to be divided into pills, each containing two grains of Calomel." *Ed.*

The proportion in which opium is united with calomel to meet different indications is so various, that such a combination as the above is scarcely a proper subject for officinal direction. W.

PILULÆ CATHARTICÆ COMPOSITÆ. *U.S. Compound Cathartic Pills.*

"Take of Compound Extract of Colocynth, in powder, *half an ounce*; Extract of Jalap, in powder, Mild Chloride of Mercury [Calomel], each, *three drachms*; Gamboge, in powder, *two scruples*. Mix them together; then with water form them into a mass, to be divided into one hundred and eighty pills." *U. S.*

This cathartic compound was first made officinal in the second edition of the U.S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action, and a peculiar tendency to the biliary organs. Such an officinal preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk was accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel; and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. Nor is it difficult, in this case, to reconcile the result of observation with physiological principles. Cathartic medicines act on different parts of the alimentary canal and organs secreting into it. In small doses, both the irritation which they occasion and their purgative effect are proportionably lessened. If several are administered at the same time, each in a diminished dose, it is obvious that the combined purgative effect of all will be experienced, while the irritation, being feeble in each part affected, and diffused over a larger space, will be less sensible to the patient, and will more readily subside. In the compound cathartic pills, most of the active purgatives in common use are associated together in proportions corresponding with their respective doses, so that an excess of any one ingredient is guarded against, and violent irritation from this cause prevented. The name of the preparation may at first sight seem objectionable, as it might be applied to any compound pills possessing cathartic properties; but when it is considered that the ingredients cannot all be expressed in the title, that no one is sufficiently prominent to give a designation to the whole, and that the preparation is intended as the representative of numerous cathartics, and calculated for a wide range of application, the name will not be considered an inexcusable deviation from ordinary medical nomenclature.

Three of the pills, containing $10\frac{2}{3}$ grains of the mass, are a medium dose for an adult. In this quantity are four grains of compound extract of colocynth, three of extract of jalap, three of calomel, and two-thirds of a grain of gamboge. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required; but is particularly applicable to the early stages of bilious fevers, to hepatitis, jaundice, and all those derangements of the alimentary canal or of the general health which depend on congestion of the portal circle. W.

PILULÆ COLOCYNTHIDIS COMPOSITÆ. *Dub.* **PILULÆ COLOCYNTHIDIS.** *Ed.* *Compound Pills of Colocynth.*

"Take of Socotrine or East India Aloes, and Scammony, of each, *eight parts*; Colocynth *four parts*; Sulphate of Potash and Oil of Cloves, of each, *one part*; Rectified Spirit *a sufficiency*. Pulverize the Aloes, Scammony, and Sulphate of Potash together; mix with them the Colocynth previously reduced to fine powder, add the Oil of Cloves; and with the aid of a small quantity of Rectified Spirit beat the whole into a proper pill mass; which is to be divided into five grain pills." *Ed.*

"Take of Hepatic Aloes, Scammony, each, *an ounce*; Pulp of Colocynth *half an ounce*; Castile Soap *two drachms*; Sulphate of Potassa, Oil of Cloves, each, *a drachm*; Molasses *a sufficient quantity*. Reduce the Aloes and Scammony to powder with the Sulphate of Potassa; then mix the Pulp of Colocynth and the Oil, and lastly, rub all together into a mass with the Soap and Molasses." *Dub.*

The sulphate of potassa, in these formulæ, is intended to promote the more complete division of the aloes and scammony. Rectified spirit has been substituted, in the last edition of the Edinburgh Pharmacopœia, for mucilage of gum Arabic before used; because it is believed to be retained by the mass more firmly than water, and thus to preserve the due consistence longer. The preparation is actively cathartic in the dose of from eight to sixteen grains. W.

PILULÆ COLOCYNTHIDIS ET HYOSCYAMI. *Ed.* *Pills of Colocynth and Henbane.*

"Take of the Colocynth-pill mass *two parts*; Extract of Hyoscyamus *one part*. Beat them well together, adding a few drops of Rectified Spirit if necessary; and divide the mass into five grain pills." *Ed.*

It is asserted that the compound pill or extract of colocynth is almost entirely deprived of its griping tendency by combination, as above, with the extract of hyoscyamus, without losing any of its purgative power. The dose is from five to twenty grains. W.

PILULÆ CONII COMPOSITÆ. *Lond.* *Compound Pills of Hemlock.*

"Take of Extract of Hemlock *five drachms*; Ipecacuanha, in powder, *a drachm*; Mixture [Mucilage] of Gum Arabic *a sufficient quantity*. Beat them together until they are incorporated." *Lond.*

An anodyne and expectorant combination useful in chronic bronchial diseases. The dose is five grains three times a day. W.

PILULÆ COPAIBÆ. *U.S.* *Pills of Copaiba.*

"Take of Copaiba *two ounces*; Magnesia, recently prepared, *a drachm*. Mix them, and set the mixture aside till it concretes into a pilular mass, which is to be divided into two hundred pills. *U.S.*

When copaiba is mixed with pure magnesia, it gradually loses its fluid consistence, forming at first a soft tenacious mass, and ultimately becoming dry, hard, and brittle. The quantity of magnesia, and the length of time requisite for the production of this change, vary with the condition of the copaiba; being greater in proportion to the fluidity of this substance, or, in other words, to the amount of volatile oil which it contains. The quantity of magnesia directed by the Pharmacopœia, one-sixteenth of the weight of the copaiba, is sufficient to solidify the latter, as it is often found in the shops, in the course of six or eight hours; but when the copaiba is fresh, or has been kept in closely stopped bottles, and retains, therefore, nearly the whole of its volatile oil, it is necessary either to augment the proportion of magnesia, or to expose the mixture for a much longer time, or to diminish the volatile oil of the copaiba by evaporation. The magnesia combines chemically with the resin, but, in relation to the volatile oil, acts merely as an absorbent; for, when the solidified mass is submitted to the action of boiling alcohol, a part is dissolved, abandoning the magnesia with which it was mixed, while the resin combined with another portion of the earth remains undissolved. (*Journ. de Pharm.* xvii. 105.) According to Guibourt, copaiba not solidifiable by magnesia, may be made so by adding one-sixth of Bordeaux or common European turpentine. (*Journ. de Pharm.* xxv. 499.) In the preparation of the pills of copaiba, care should be taken to divide the mass before it has become too hard. The advantage of this preparation is, that the copaiba is brought to the state of pill with little increase of its bulk. Each pill contains nearly five grains of copaiba, and from two to six may be taken for a dose twice or three times a day.

Hydrate of lime produces the same effect as magnesia, and, as stated by M. Thierry, in a shorter time, if employed according to a formula which he proposes. He takes 15 parts of copaiba and one part of slaked lime, mixes them in a marble mortar, transfers the mixture to an open vessel, places this upon a sand-bath, and sustains the heat for four hours, occasionally stirring. It is necessary that the hydrate of lime should have been freshly prepared from recently-burnt lime. The mixture loses only a twenty-fourth of its weight, which is chiefly the water of the hydrate. (*Journ. de Pharm.* N. S. i. 310.) W.

PILULÆ CUPRI AMMONIATI. *Ed. Pills of Ammoniated Copper.*

"Take of Ammoniated Copper, in fine powder, *one part*; Bread-crumbs *six parts*; Solution of Carbonate of Ammonia *a sufficiency*. Beat them into a proper mass, and divide it into pills, containing each half a grain of ammoniated copper." *Ed.*

This is a convenient form for administering ammoniated copper. One pill may be given night and morning, and the dose gradually increased to five or six pills. W.

PILULÆ DIGITALIS ET SCILLÆ. *Ed. Pills of Digitalis and Squill.*

"Take of Digitalis and Squill, of each, *one part*; Aromatic Electuary *two parts*. Beat them into a proper mass with Conserve of Red Roses; and divide the mass into four grain pills." *Ed.*

These pills combine the diuretic properties of digitalis and squill, and may be given in dropsy. One or two pills constitute a dose. W.

PILULÆ FERRI CARBONATIS. U.S., Ed. *Pills of Carbonate of Iron. Vallet's Ferruginous Pills.*

"Take of Sulphate of Iron *four ounces*; Carbonate of Soda *five ounces*; Clarified Honey *two ounces and a half*; Syrup, boiling Water, each, *a sufficient quantity*. Dissolve the Sulphate of Iron and Carbonate of Soda, each, in a pint of the Water, and to each solution add a fluidounce of Syrup; then mix the two solutions in a bottle just large enough to contain them, close it accurately with a stopper, and set it by that the carbonate of iron may subside. Pour off the supernatant liquid, and, having washed the precipitate with warm water, sweetened with Syrup in the proportion of a fluidounce of the latter to a pint of the former, until the washings no longer have a saline taste, place it upon a flannel cloth, and express as much of the water as possible; then immediately mix it with the Honey. Lastly, heat the mixture, by means of a water-bath, until it attains a pilular consistence." U.S.

"Take of the Saccharine Carbonate of Iron *four parts*; Conserve of Red Roses *one part*. Beat them into a proper mass, to be divided into five grain pills." Ed.

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharatum* and *Liquor Ferri Iodidi*. The U. S. pill of carbonate of iron is another example of a ferruginous preparation, in which the iron is protected from oxidation by the same means. The salts employed are the same as those used for obtaining the officinal subcarbonate of iron; but, in forming that preparation, the carbonate which first precipitates absorbs oxygen and loses nearly all its carbonic acid in the processes of washing and drying. When, however, as in the U. S. formula, above given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with the same substance, the absorption of oxygen and loss of carbonic acid, during the separation of the precipitate, are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey, and evaporation by means of a water-bath. Of course it is essential to the success of this process, that the sulphate of iron should be pure; otherwise some sesquioxide will be present in the product. The process just explained is that of M. Vallet, of Paris, after whom the preparation is popularly called. The *Edinburgh* pill of carbonate of iron is made in a different manner. The saccharine carbonate, a preparation peculiar to the *Edinburgh Pharmacopœia*, is brought to a pilular consistence by being mixed with conserve of roses. This process is inferior to that of Vallet; for in the first place, the saccharine carbonate is admitted to contain sesquioxide of iron, and secondly, conserve of roses is a less efficient preservative of the pilular mass than honey. (See *Ferri Carbonas Saccharatum*.)

Properties. The U. S. preparation is in the form of a soft pilular mass, of a uniform black colour and strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of carbonate of protoxide of iron. The *Edinburgh* pill may be supposed to contain one-third of ferruginous matter.

Medical Properties and Uses. The U. S. pill of carbonate of iron, or Vallet's ferruginous mass, is admirably adapted to cases in which ferruginous preparations are indicated. It is considered particularly useful in chlorosis, amenorrhœa, and other female complaints, and appears to act favourably by increasing the colouring matter of the blood, causing the capillary system to become more fully injected, and the lips to assume a

redder colour. It may be given in divided doses to the extent of from ten to thirty grains in the course of the day, and continued for a month or six weeks, if improvement takes place. As the mass is not divided in the U. S. formula, it is necessary in prescription to indicate the weight of each pill, which may vary from three to five grains, according to the views of the prescriber. There can be but little doubt, that in cases in which the alterative effects of iron are called for, Vallet's preparation is superior to any other derived from that metal. Its chief merits are its unchangeableness and ready solubility in acids. For further information respecting it, see the favourable report made on Vallet's ferruginous pills to the French Royal Academy of Medicine, in 1837, by M. Soubeiran, republished in the *Amer. Journ. of Pharm.* x. 244, and the paper on carbonate of iron by Mr. Wm. Procter, Jr., contained in the same journal, x. 272. B.

PILULÆ FERRI COMPOSITÆ. *U. S., Lond., Dub. Compound Pills of Iron.*

"Take of Myrrh, in powder, *two drachms*; Carbonate of Soda, Sulphate of Iron, each, *a drachm*; Syrup *a sufficient quantity*. Rub the Myrrh with the Carbonate of Soda; then add the Sulphate of Iron, and again rub them; lastly, beat them with the Syrup so as to form a mass, to be divided into eighty pills." *U. S.*

The directions of the British Colleges are essentially the same as the above. The *London College* orders *a drachm* of molasses, the *Dublin*, *a drachm* of brown sugar, instead of the syrup. With brown sugar alone, the reaction of the materials in our climate does not always produce sufficient moisture to give the mass a pilular consistence. The direction for dividing the mass into pills is peculiar to our Pharmacopœia.

This preparation is closely analogous to the *Mistura Ferri Composita* in properties and composition. It is a good emmenagogue and antihæctic tonic. As its peculiar advantages depend upon the presence of carbonate of protoxide of iron, which speedily changes into the sesquioxide on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. From two to six pills may be given at a dose, three times a day. W.

PILULÆ FERRI SULPHATIS. *Ed. Pills of Sulphate of Iron.*

"Take of Dried Sulphate of Iron *two parts*; Extract of Taraxacum *five parts*; Conserve of Red Roses *two parts*; Liquorice-root powder *three parts*. Beat them together into a proper mass, which is to be divided into five grain pills." *Ed.*

There may be some doubt of the propriety of mixing the sulphate of iron with the confection of roses, by the tannic acid of which it must be decomposed. The dose is from five to twenty grains. W.

PILULÆ GALBANI COMPOSITÆ. *U. S., Lond., Dub. PILULÆ ASSAFÆTIDÆ. Ed. Compound Pills of Galbanum.*

"Take of Galbanum, Myrrh, each, *an ounce and a half*; Assafetida *half an ounce*; Syrup *a sufficient quantity*. Beat them together so as to form a mass, to be divided into four hundred and eighty pills." *U. S.*

The *London College* directs of Galbanum *an ounce*, of Myrrh and Sagapenum, each, *an ounce and a half*, of Assafetida, *half an ounce*, and of Syrup *a sufficient quantity*; and orders them to be beaten together until thoroughly incorporated. The *Dublin College* gives the same directions, substituting molasses for the syrup. The *Edinburgh College* takes of assafetida, gal-

banum, and myrrh, each, *three parts*, conserve of red roses *four parts* or a sufficient quantity, mixes them, and beats them into a proper pilular mass.

This compound is given as an antispasmodic and emmenagogue in chlorosis and hysteria. The dose is from ten to twenty grains. W.

PILULÆ GAMBOGIÆ COMPOSITÆ. *Dub.* PILULÆ CAMBOGIÆ COMPOSITÆ. *Lond.* PILULÆ CAMBOGIÆ. *Ed.* *Compound Pills of Gamboge.*

"Take of Gamboge, in powder, *a drachm*; Aloes, in powder, *a drachm and a half*; Ginger, in powder, *half a drachm*; Soap *two drachms*. Mix the powders together; then add the Soap, and beat the whole together till they are thoroughly incorporated." *Lond.*

The *Dublin* formula differs from the above only in designating hepatic aloes, and in the addition of molasses to impart more readily the pilular consistence.

The *Edinburgh College* takes of gamboge, East India or Barbadoes aloes, and aromatic powder, each, *one part*, and of Castile soap *two parts*; pulverizes the gamboge and aloes separately, mixes all the powders, adds the soap, and then a sufficiency of syrup; and beats the whole into a proper pill mass.

This is an active purgative pill; and may be given in the dose of ten or fifteen grains. The formula is that of Dr. George Fordyce simplified. W.

PILULÆ HYDRARGYRI. *U.S., Lond., Ed., Dub.* *Mercurial Pills. Blue Pills.*

"Take of Mercury *an ounce*; Confection of Roses *an ounce and a half*; Liquorice Root, in powder, *half an ounce*. Rub the Mercury with the Confection till all the globules disappear; then add the Liquorice Root, and beat the whole into a mass, to be divided into four hundred and eighty pills." *U.S.*

The process of the *London College* is the same with the above, one quarter only of the quantity of materials being used. The *Dublin* process differs from the London only in substituting extract of liquorice root for the root itself. Neither of these Colleges orders the mass to be divided into pills. The *Edinburgh* process corresponds with that of the *U.S. Pharmacopœia*, except that the relative quantity of the ingredients is expressed in parts, and the mass is divided into five grain pills.

This preparation is very generally known by the name of *blue pill*. The mercury constitutes one-third of the mass; and consequently the pill of our *Pharmacopœia*, which weighs three grains, contains one grain of the metal.

The condition of the mercury in this preparation is a point which has not yet been precisely determined. There is no doubt that by far the greater portion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into the black or protoxide of mercury, and that this is the ingredient upon which the activity of the pill depends. The supposed oxidation is attributed partly to the influence of the air upon the surface of the metal, greatly extended by the separation of its particles, partly to the action of the substance used in the trituration. If the mercury be not oxidized during the trituration, there can be little doubt that it becomes so to a slight extent by subsequent exposure. The obvious changes which the mass undergoes by time can be explained in no other way; and protoxide of mercury is asserted to have been actually extracted from the old mercurial pill. Nevertheless, it scarcely admits of dispute that the metal, quite independently of oxidation out of the body, is capable of producing the peculiar mercurial effects upon the system when

introduced into the stomach, probably undergoing chemical changes there. All agree that the efficacy of the preparation is proportionate to the extinction of the mercury, in other words, to the degree in which the metallic globules disappear. This extinction may be effected by trituration with various substances; and manna, syrup, honey, liquorice, mucilage, soap, and guaiac have been recommended, among others, for this purpose; but the confection of roses has been adopted in all the Pharmacopœias, as affording greater facilities, and being less liable to objection than any other. The mercury is known to be completely extinguished, when, upon rubbing a small portion of the mass with the end of the finger upon a piece of paper or glass, no metallic globules appear. The powdered liquorice root is added in order to give the due degree of consistence to the mass. As the trituration requires to be continued a considerable length of time, and renders the process very laborious, it is customary in Great Britain to prepare the mass by machinery; and at Apothecaries' Hall, in London, the trituration is effected by the agency of steam. The machine there employed consists of "a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axis." The preparation slowly changes colour upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury. Much of the *mercurial pill* employed in this country is imported from England.

It has been proposed to prepare mercurial pills by rubbing the metal with extract of dandelion, and as the latter is thought to possess useful alterative properties in hepatic disease, the combination may sometimes be usefully employed; but it cannot take the place of the officinal preparation.

Medical Properties and Uses. These pills are among the mildest of the mercurial preparations, being less liable than most of the others to act upon the bowels, and exercising the peculiar influence of the remedy upon the system with less general irritation. They are much employed for producing the sialagogue and alterative action of mercury. For the former purpose, one pill may be given two or three times a day; and if the case be urgent, the dose may be increased. Even this preparation sometimes disturbs the bowels. It should then be given combined with a small proportion of opium, or in very minute doses, as half a grain or a grain of the mass repeated every hour or two through the day, so as to allow of its absorption before a sufficient quantity has been administered to act as an irritant. With a view to the alterative effect of the preparation upon the digestive organs, one pill may be given every night, or every other night, at bedtime, and followed in the morning, if the bowels should not be opened, by a small dose of some laxative medicine. From five to fifteen grains of the mass are occasionally given as a cathartic, in cases requiring a peculiar impression upon the liver; but, when used for this purpose, it should always either be combined or speedily followed by a more certain purgative. The *blue mass* may frequently be administered with advantage, suspended in water by the intervention of thick mucilage; and it forms an excellent addition to the chalk mixture in diarrhœa, particularly that of children, when the biliary secretion is deficient, or otherwise deranged. W.

PILULÆ HYDRARGYRI CHLORIDI MITIS. U.S. *Pills of Mild Chloride of Mercury. Calomel Pills.*

"Take of Mild Chloride of Mercury [Calomel] *half an ounce*; Gum Arabic, in powder, *a drachm*; Syrup *a sufficient quantity*. Mix together the Chloride of Mercury and the Gum; then beat them with the syrup so as to form a mass, to be divided into two hundred and forty pills." U.S.

This is a convenient form for administering calomel, of which one grain is contained in each pill. Soap, which was directed in the preparation of this pill in the first edition of the Pharmacopœia, is objectionable on account of its chemical incompatibility with calomel. Mucilage of gum Arabic alone does not form a sufficiently plastic mass; but gum and syrup united, as in the officinal formula, answer admirably well, forming a mass which is easily made into pills, and which readily yields to the solvent power of the stomach. W.

PILULÆ HYDRARGYRI IODIDI. *Lond. Pills of Iodide of Mercury.*

"Take of Iodide of Mercury *a drachm*; Confection of the Dog Rose *three drachms*; Ginger, in powder, *a drachm*. Beat them together until they are incorporated." *Lond.*

The dose of this preparation is from five to ten grains. W.

PILULÆ IPECACUANHÆ COMPOSITÆ. *Lond. Compound Pills of Ipecacuanha.*

"Take of Compound Powder of Ipecacuanha [Dover's powder] *three drachms*; Squill, recently dried, Ammoniac, each, *a drachm*; Mixture [Mucilage] of Gum Arabic *a sufficient quantity*. Beat them together until they are incorporated." *Lond.*

An anodyne, somewhat stimulating, and expectorant combination, applicable to cases of chronic bronchial disease. The dose is from five to ten grains. W.

PILULÆ IPECACUANHÆ ET OPII. *Ed. Pills of Ipecacuanha and Opium.*

"Take of Powder of Ipecacuanha and Opium *three parts*; Conserve of Red Roses *one part*. Beat them into a proper mass, which is to be divided into four grain pills." *Ed.*

This is merely the Dover's powder in a pilular form; as there can scarcely be a doubt, that the College intended by the name "powder of ipecacuanha and opium," to designate the preparation which they now call "compound powder of ipecacuanha." These pills are narcotic and sudorific. The quantity of the mass equivalent to a grain of opium is about thirteen grains; but it is usually employed in smaller doses. W.

PILULÆ OPII. *U.S. PILULÆ OPII sive THEBAICÆ. Ed. Pills of Opium.*

"Take of Opium, in powder, *a drachm*; Soap *twelve grains*. Beat them with water so as to form a mass, to be divided into sixty pills." *U.S.*

"Take of Opium *one part*; Sulphate of Potassa *three parts*; Conserve of Red Roses *one part*. Beat them into a proper mass, which is to be divided into five grain pills." *Ed.*

The process of the U.S. Pharmacopœia is designed merely to furnish a convenient formula for putting opium into the pilular form, preferable to the mode sometimes practised of making the pills directly from the unpowdered mass of opium as found in commerce. The soap answers no other purpose than to give a due consistence, and is therefore in small proportion. Each pill contains a grain of opium.

The object intended to be answered by the Edinburgh preparation is somewhat uncertain. The proportion of the opium corresponds with that in the *Pilulæ Saponis Compositæ* of the other Pharmacopœias, but the name given to the preparation indicates that there could be no intention to conceal its nature; while the direction to divide the mass into pills of five

grains, each containing a grain of opium, shows that the design was not to offer the means of exhibiting small doses of that narcotic in the pilular form. The object probably was merely to separate the particles of opium by the intervention of soap, and thus to render it more soluble in the gastric liquors. In this case, the preparation ranks rather with the U. S. *pills of opium*, with which we place it, than with the *compound soap pill*.

Of either of these pills, one is a medium dose in reference to the full effects of opium. W.

PILULÆ PLUMBI OPIATÆ. *Ed. Opiate Pills of Lead.*

"Take of Acetate of Lead *six parts*; Opium *one part*; Conserve of Red Roses about *one part*. Beat them into a proper mass, which is to be divided into four grain pills. This pill may be made also with twice the quantity of opium." *Ed.*

This pill would be better left to extemporaneous prescription; the requisite proportion of opium to the acetate of lead varying constantly in different cases. Besides, to have two preparations under the same name, one containing twice as much opium as the other, must lead to great confusion, and is altogether objectionable. The tannic acid of the confection of roses will decompose a portion of the acetate; but the resulting tannate of lead is not inert. Each pill contains three grains of acetate of lead, which is generally too much for a commencing dose. W.

PILULÆ QUININÆ SULPHATIS. *U. S. Pills of Sulphate of Quinia.*

"Take of Sulphate of Quinia *an ounce*; Gum Arabic, in powder, *two drachms*; Syrup *a sufficient quantity*. Mix together the Sulphate of Quinia and the Gum; then beat them with the Syrup so as to form a mass, to be divided into four hundred and eighty pills." *U. S.*

Each pill contains a grain of sulphate of quinia, and twelve are equivalent to an ounce of good Peruvian bark. W.

PILULÆ RHEI. *U. S., Ed. Pills of Rhubarb.*

"Take of Rhubarb, in powder, *six drachms*; Soap *two drachms*. Beat them with water so as to form a mass, to be divided into one hundred and twenty pills." *U. S.*

"Take of Rhubarb, in fine powder, *nine parts*; Acetate of Potash *one part*; Conserve of Red Roses *five parts*. Beat them into a proper mass, and divide it into five grain pills." *Ed.*

Rhubarb is so often given in the pilular form, that it is convenient both for the physician and apothecary to have an officinal formula, indicating the mode of preparing the pills, as well as the quantity of rhubarb to be contained in each. Soap, as directed by the U. S. Pharmacopœia, has stood the test of long experience as a good excipient for rhubarb. The medicine is sufficiently disposed to constipate without the addition of the confection of roses ordered by the Edinburgh College. The acetate of potassa directed by the College is probably intended to keep the pill soft. The U. S. formula is decidedly preferable. According to both, each pill contains three grains of rhubarb. W.

PILULÆ RHEI COMPOSITÆ. *U. S., Lond., Ed. Compound Pills of Rhubarb.*

"Take of Rhubarb, in powder, *an ounce*; Aloes, in powder, *six drachms*; Myrrh, in powder, *half an ounce*; Oil of Peppermint *half a fluidrachm*; Syrup of Orange Peel *a sufficient quantity*. Beat the whole together so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

The *London College* takes the *same quantities* of powdered rhubarb, aloes, and myrrh; mixes them; then adds *a drachm* of soap, *half a fluidrachm* of oil of caraway, and *sufficient* syrup; and beats them all together. The *Edinburgh College* takes of rhubarb *twelve parts*, aloes *nine parts*, myrrh and Castile soap, each, *six parts*, oil of peppermint *one part*, and conserve of red roses *five parts*; mixes them, and beats them into a mass, which is divided into five grain pills. This College also allows the pills to be made without oil of peppermint, when so preferred.

This is a warm tonic laxative, useful in costiveness with debility of stomach. From two to four pills, or from ten to twenty grains of the mass, may be taken twice a day.

W.

PILULÆ RHEI ET FERRI. *Ed. Pills of Rhubarb and Iron.*

"Take of Dried Sulphate of Iron *four parts*; Extract of Rhubarb *ten parts*; Conserve of Red Roses *five parts*. Beat them into a proper pill mass, and divide it into five grain pills." *Ed.*

Tonic and laxative in the dose of two or three pills.

W.

PILULÆ SAGAPENI COMPOSITÆ. *Lond. Compound Pills of Sagapenum.*

"Take of Sagapenum *an ounce*; Aloes *half a drachm*; Syrup of Ginger *a sufficient quantity*. Beat them together until they are incorporated." *Lond.*

A stimulant, antispasmodic, and laxative preparation, which may be used in cases of flatulent colic, with costiveness, dependent on deficient irritability of the bowels. The dose is from ten to thirty grains.

W.

PILULÆ SAPONIS COMPOSITÆ. *U.S., Lond. PILULÆ SAPONIS CUM OPIO. Dub. Compound Pills of Soap.*

"Take of Opium, in powder, *half an ounce*; Soap *two ounces*. Beat them together so as to form a pilular mass." *U.S.*

The directions of the *London* and *Dublin Colleges* correspond with those of the *U.S. Pharmacopœia*.

This preparation is useful by affording the opportunity of conveniently administering opium, in a pilular and readily soluble form, in small fractions of a grain. The name adopted in the *U.S.* and *London Pharmacopœias* was probably intended to conceal the nature of the preparation from the patient. That of the *Dublin College* is inappropriate; as opium, though in small proportion as to quantity, is yet the ingredient of greatest importance, and that which gives character to the pill. One grain of opium is contained in five of the mass.

W.

PILULÆ SCILLÆ COMPOSITÆ. *U.S., Lond., Dub. PILULÆ SCILLÆ. Ed. Compound Pills of Squill.*

"Take of Squill, in powder, *a drachm*; Ginger, in powder, Ammoniac, in powder, each, *two drachms*; Soap *three drachms*; Syrup *a sufficient quantity*. Mix the powders together; then beat them with the Soap, and add the Syrup so as to form a mass, to be divided into one hundred and twenty pills." *U.S.*

The *London College* employs the same materials, in the same quantities, and proceeds in the same manner, except that the mass is not divided into pills. The *Dublin* process differs from the *London* only in employing *three drachms* of ginger, in adding the ammoniac without previously powdering it, and in giving the due consistence by molasses instead of syrup. The *Edinburgh College* takes of squill, in fine powder, *five parts*; ammoniac, ginger in fine powder, and Spanish soap, each, *four parts*; conserve

of red roses *two parts*; mixes the powders; then adds the other ingredients; and beats them into a uniform mass, which is divided into five grain pills.

This is a stimulant expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of chronic affections of the bronchial mucous membrane. From five to ten grains may be given three or four times a day. The preparation should be made when wanted for immediate use, as the squill which it contains is liable to be injured by keeping. W.

PILULÆ STYRACIS COMPOSITÆ. *Lond.* PILULÆ STYRACIS. *Ed.* PILULÆ E STYRACE. *Dub.* *Compound Pills of Storax.*

“Take of Storax, strained, *three drachms*; hard Opium, in powder, Saffron, each, *a drachm*. Beat them together until they are thoroughly incorporated.” *Lond.*

The process of the *Dublin College* is essentially the same as the above. The *Edinburgh College* takes of opium and saffron, each, *one part*, and of extract of storax *two parts*, and beats them into a uniform mass, which is divided into five grain pills.

In these pills the storax and saffron are added merely to conceal the taste and smell of the opium, as the name of the pills is intended to conceal their real character. This contrivance is deemed necessary; as some individuals have a prejudice against the use of opium, which reason cannot overcome. Five grains of the mass contain a grain of opium. W.

PLUMBUM.

Preparations of Lead.

LIQUOR PLUMBI SUBACETATIS. *U.S.* LIQUOR PLUMBI DIACETATIS. *Lond.* PLUMBI SUBACETATIS LIQUOR. *Dub.* PLUMBI DIACETATIS SOLUTIO. *Ed.* *Solution of Subacetate of Lead.*

“Take of Acetate of Lead *sixteen ounces*; Semivitrified Oxide of Lead, in fine powder, *nine ounces and a half*; Distilled Water *four pints*. Boil them together in a glass or porcelain vessel for half an hour, occasionally adding Distilled Water so as to preserve the measure, and filter through paper. Keep the solution in closely stopped bottles.” *U.S.* The sp. gr. of this solution is 1·267.

“Take of Acetate of Lead *two pounds and three ounces*; Oxide of Lead [Litharge], rubbed into powder, *a pound and four ounces*; Water *six pints* [Imperial Measure]. Boil for half an hour, occasionally stirring, and, when the solution has cooled, add enough Distilled Water to make it fill six pints; lastly filter.” *Lond.* The sp. gr. of the solution is 1·260.

“Take of Acetate of Lead *six ounces and six drachms*; Litharge, in fine powder, *four ounces*; Water *a pint and a half* [Imperial measure]. Boil the Salt and Litharge with the Water for half an hour, stirring occasionally. When the solution is cold add Water, if necessary, to make up a pint and a half; and then filter. Preserve the solution in well-closed bottles.” *Ed.*

“Take of Semivitrified Oxide of Lead *one part*; Distilled Vinegar *twelve parts*. Boil together in a glass vessel until eleven parts of the fluid remain; then let the liquor rest, and when the impurities have subsided, let it be filtered.” *Dub.*

Crystallized acetate of lead consists of one equivalent of acetic acid 51·48, one of protoxide of lead 111·6, and three of water 27=190·08. Litharge as usually found in the shops is an impure protoxide of lead. When a solu-

tion of the former is boiled with the latter, a large quantity of the protoxide is dissolved, and a subacetate of lead is formed which remains in solution. The precise composition of the subacetate varies with the proportions of acetate of lead and of litharge employed. When the quantity of the latter exceeds that of the former by one-half or more, the acetic acid of the acetate unites, according to the highest chemical authorities, with two additional equivalents of protoxide, forming a trisacetate; when the two substances are mixed in proportions corresponding with their equivalent numbers, that is, in the proportion of 190.08 of salt to 111.6 of oxide, or 10 to 6 nearly, only one additional equivalent of protoxide unites with the acid, and a diacetate of lead is produced. As the quantity of litharge directed in the former U.S. Pharmacopœia was intermediate between these proportions, it is probable that the solution which resulted contained both the diacetate and trisacetate. In the present edition, the proportions have been so arranged as to result in the production of the diacetate; and the preparation is thus rendered identical or nearly so with those of the London and Edinburgh Colleges. The former of these Colleges originally prepared this solution by boiling together vinegar and litharge, but, in the last edition of their Pharmacopœia, a process was adopted analogous to that of our national standard. The preparation was newly introduced into the recent edition of the Edinburgh Pharmacopœia. In executing the process, the litharge should be employed in the state of very fine powder, and, according to Thenard, should be previously calcined in order to decompose the carbonate of lead, which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate.

The process of the Dublin College also results in the production of a subacetate of lead; one equivalent of the acetic acid of the vinegar combining directly with two equivalents of the protoxide of the litharge, to form a diacetate. That a trisacetate is not produced may be inferred from the fact ascertained by Dr. Barker, that distilled vinegar dissolves only about one-twelfth of its weight of the litharge, which is not nearly sufficient to afford three equivalents of protoxide to one of the acid. Besides, according to Phillips and Duncan, the resulting salt has been proved by the analysis of Dr. Bostock to be composed of one equivalent of acid and two of base. The strength of the solution necessarily varies with the strength of the vinegar, and this is an objection against the Dublin process, to which the others are not equally liable. We are told by Phillips, that the sp. gr. of the solution prepared with distilled vinegar of 1.007 is 1.220, with that of 1.009 is 1.309; while Dr. Barker states that the specific gravity of the saturated solution prepared by himself with distilled vinegar, to be only 1.118 at 68°. Common vinegar yields a dark brown solution, and is therefore not employed.

Properties. The solution of subacetate of lead of the U.S., Edinburgh, and London Pharmacopœias is colourless, that of the Dublin College has a pale greenish-straw colour, arising from impurities in the distilled vinegar. Its taste is sweetish and astringent. When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Dr. Barker, are flat rhomboidal prisms with dihedral summits. It has an alkaline reaction, tinging the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which it is decomposed. Carbonic acid throws down a white precipitate of carbonate of lead, and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbonic acid from the atmosphere. It affords precipitates also with the alkalies, alkaline earths,

and their carbonates, with sulphuric and muriatic acids free or combined, with hydrosulphuric acid and the hydrosulphates, with the soluble iodides and chlorides, and, according to Thenard, with solutions of all the neutral salts. Solutions of gum, tannin, most vegetable colouring principles, and many animal substances, particularly albumen, produce with it precipitates consisting of the substance added and oxide of lead. It should be kept in well stopped bottles. It is known to contain a salt of acetic acid by emitting an acetous smell when treated with sulphuric acid; and a salt of lead by yielding a white precipitate with an alkaline carbonate, a yellow one with iodide of potassium, and a black one with hydrosulphuric acid. It is distinguished from the solution of acetate of lead by being precipitated by gum Arabic.

Medical Properties and Uses. This solution is astringent and sedative, but is employed only as an external application. It is highly useful in inflammation arising from sprains, bruises, burns, blisters, &c., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. From four fluidrachms to a fluidounce, added to a pint of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker, as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action; but we have not witnessed such an effect. The solution has the common name of *Goulard's extract*, derived from a surgeon of Montpellier by whom it was introduced into general notice, though previously employed.

Off. Prep. Ceratum Plumbi Subacetatis, *U. S., Lond.*; Ceratum Saponis. *U. S.*; Liquor Plumbi Subacetatis Dilutus, *U. S., Lond., Dub.*; Plumbi Oxydum Hydratum, *Lond.* W.

LIQUOR PLUMBI SUBACETATIS DILUTUS. *U. S.* LIQUOR PLUMBI DIACETATIS DILUTUS. *Lond.* PLUMBI SUBACETATIS LIQUOR COMPOSITUS. *Dub.* *Diluted Solution of Subacetate of Lead. Lead-water.*

“Take of Solution of Subacetate of Lead *two fluidrachms*; Distilled Water *a pint*. Mix them.” *U. S.*

The *London College* mixes *a fluidrachm and a half* of the solution with *a pint* [Imperial measure] of distilled water, and *two fluidrachms* of proof spirit; the *Dublin*, *a fluidrachm* of the solution, with *a pint* of distilled water, and *a fluidrachm* of proof-spirit.

This preparation is convenient; as, in consequence of the subsidence of the carbonate of lead usually formed on the dilution of the strong solution, it enables the apothecary to furnish clear lead-water when it is called for. The strength, though doubled in the last edition of the *U. S. Pharmacopœia*, might be still further increased without disadvantage. The British preparations are much too feeble. The old French Codex directed two drachms of the strong solution to a pound of distilled water, and an ounce of alcohol of 22° Baumé, and thus formed the *vegeto-mineral water* of Goulard. The minute proportion of proof-spirit added by the British Colleges can have little sensible effect. W.

PLUMBI CHLORIDUM. *Lond.* *Chloride of Lead.*

“Take of Acetate of Lead *nineteen ounces*; boiling Distilled Water *three pints* [Imperial measure]; Chloride of Sodium *six ounces*. Dissolve separately the Acetate of Lead and Chloride of Sodium, the former in *three pints* of Distilled Water, the latter in *one pint* of Distilled Water. Then mix the solutions, and wash the precipitate, after it has become cool, with Distilled Water, and dry it.” *Lond.*

In this process, a mutual decomposition of the acetate of lead and chloride of sodium takes place; the sodium of the latter changing place with the lead of the former, so as to produce acetate of soda which remains in solution, and chloride of lead which is precipitated.

Chloride of lead is soluble in thirty parts of water at 60° and in twenty-two parts at 212° , and from its saturated boiling solution separates in small, brilliant, anhydrous crystals. It is colourless and fusible, and, upon cooling after fusion, assumes a horn-like appearance, from which it has received the name of *horn lead*. The London College gives as characters of it, besides its relation with water above mentioned, that it becomes yellow with heat, and black upon the addition of hydrosulphuric acid. It was introduced into the last edition of the London Pharmacopœia merely as one of the substances employed in the preparation of muriate of morphia. W.

PLUMBI IODIDUM. *Lond., Ed. Iodide of Lead.*

"Take of Acetate of Lead *nine ounces*; Iodide of Potassium *seven ounces*; Distilled Water *a gallon* [Imperial measure]. Dissolve the Acetate of Lead in six pints of the Water and filter; and to these add the Iodide of Potassium previously dissolved in *two pints* of the Water. Wash the precipitate and dry it." *Lond.*

"Take of Iodide of Potassium and Nitrate of Lead, of each, *an ounce*; Water *a pint and a half* [Imperial measure]. Dissolve the salts separately, each in one-half of the Water; add the solutions; collect the precipitate on a filter of linen or calico, and wash it with water. Boil the powder in three gallons of water acidulated with three fluidounces of pyroligneous acid. Let any undissolved matter subside, maintaining the temperature near the boiling point; and pour off the clear liquor, from which the iodide of lead will crystallize on cooling." *Ed.*

In the process of the London College, the acetate of lead gives up its metal to the iodine from which it receives the potassium—the operation taking place between single equivalents of the several ingredients. The acetate of potassa thus formed remains in solution, while the iodide of lead is precipitated. The saturating proportions of crystallized acetate of lead and iodide of potassium are 190.08 of the former and 165.45 of the latter, or 9 to 7.83; so that the acetate is slightly in excess. The proportions should be as nearly as possible those of exact saturation. An excess of the iodide of potassium has the disadvantage of holding a portion of the iodide of lead in solution; while, according to Christison, an excess of lead to the iodine disposes to the formation of the lemon-yellow insoluble oxyiodide of lead. The latter result is very apt to take place; as the acetate of lead is liable to contain an excess of oxide, and the iodide of potassium is often impure. To obviate the disadvantage of an excess of oxide in the acetate, it is recommended to add a little acetic acid to the solution of this salt before mixing it with the iodide of potassium. Besides the oxyiodide above mentioned, a carbonate of lead is liable to be formed from the frequent presence of the carbonate of potassa in the iodide of potassium of the shops. It is to free the precipitated iodide of lead from these impurities that the Edinburgh College directs it to be boiled with water acidulated with acetic acid, which readily dissolves any carbonate or acetate of lead present, as well as the iodide, and deposits only the last upon cooling.

The Edinburgh College employs the nitrate instead of the acetate of lead as more easily obtained pure; but the advantage of the former salt over the latter is scarcely sufficient to warrant the introduction of a new official for this sole purpose. In the Edinburgh process, a double decomposition takes place, as in the London, resulting in the production of nitrate of po-

tassa which is retained in solution, and iodide of lead which falls. The saturating proportions are 165·75 of the nitrate and 165·45 of the iodide, or almost precisely equal quantities.

As obtained by the London process, iodide of lead is in the form of a bright yellow, heavy, tasteless, and inodorous powder. It is soluble in 1235 parts of cold water (*Soubeiran Trait. de Pharm.*), and is considerably more soluble in boiling water, which, on cooling, deposits it in minute, shining, golden-yellow, crystalline scales. In this form it is presented by the Edinburgh process. It melts by heat, and is dissipated in vapours which are at first yellow, and ultimately violet in consequence of the disengagement of the iodine. It consists of one equivalent of iodine 126·3, and one of lead 103·6 = 229·9. As a test of its purity, the Edinburgh College states that five grains are entirely dissolved, with the aid of heat, by a fluidrachm of their pyroligneous acid diluted with a fluidounce and a half of distilled water; and golden crystals are copiously deposited when the solution cools.

Medical Properties and Uses. This compound is supposed to have the resolvent properties of iodine, combined with those which are peculiar to lead, and was at one time recommended in tuberculous diseases, in which, however, it has proved wholly inefficient. It is said to have been usefully employed in the discussion of scrofulous tumours and other indolent swellings, and in the cure of obstinate ulcers; and for these purposes has been used both internally, and locally in the form of an ointment. According to Dr. Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. (*Christison's Dispensatory.*) The dose is from half a grain to three or four grains. Dr. O'Shaughnessy states that ten grains are borne without inconvenience.

Off. Prep. Unguentum Plumbi Iodidi, *Lond.*

W.

PLUMBI NITRAS. *Ed.* Nitrate of Lead.

"Take of Litharge *four ounces and a half*; Diluted Nitric Acid *a pint* [Imperial measure]. Dissolve the Litharge to saturation with the aid of a gentle heat. Filter and set the liquor aside to crystallize. Concentrate the residual liquid to obtain more crystals." *Ed.*

In this process the nitric acid unites directly with the protoxide to form the nitrate. This is in beautiful white, nearly opaque, tetrahedral or octohedral crystals, which are permanent in the air, of a sweet astringent taste, soluble in water and alcohol, and composed of one equiv. of nitric acid, 54·15, and one of protoxide of lead 111·6, without water of crystallization. When heated the salt first melts and is then decomposed, with the evolution of nitrous fumes, and a residue of metallic lead.

The nitrate of lead is not employed as a medicine; and was introduced into the Edinburgh Pharmacopœia merely as one of the substances employed in the preparation of the iodide of lead.

Off. Prep. Plumbi Iodidum, *Ed.*

W.

PLUMBI OXYDUM HYDRATUM. *Lond.* Hydrated Oxide of Lead.

"Take of Solution of Diacetate of Lead *six pints*; Distilled Water *three gallons*; Solution of Potassa *six pints*, or as much as may be required to precipitate the Oxide. Mix them, and wash the precipitate with water until nothing alkaline remains." *Lond.*

In this process the potassa takes the acetic acid of the diacetate and separates the oxide of lead, which becomes a hydrate by uniting with a portion of water at the moment of separation, and, being insoluble, is precipitated in the form of a white powder. It was introduced by the London College

into their Pharmacopœia as one of the substances employed in their process for preparing sulphate of quinia; but, as this process has not been practically adopted, the hydrated oxide of lead may be considered as altogether useless in Pharmacy.

W.

POTASSA.

Preparations of Potassa.

LIQUOR POTASSÆ. *U. S., Lond.* POTASSÆ AQUA. *Ed.* POTASSÆ CAUSTICÆ AQUA. *Dub.* *Solution of Potassa.*

“Take of Carbonate of Potassa *a pound*; Lime *half a pound*; boiling Distilled Water *a gallon*. Dissolve the Carbonate of Potassa in half a gallon of the Water. Pour a little of the Water on the Lime, and when it is slaked, add the remainder. Mix the hot liquors, and boil for ten minutes, stirring constantly; then set the mixture aside, in a covered vessel, until it becomes clear. Lastly, pour off the supernatant liquor, and keep it in well stopped bottles of green glass.” *U. S.*

“Take of Carbonate of Potassa *fifteen ounces*; Lime *eight ounces*; boiling Distilled Water *a gallon* [Imperial measure]. Dissolve the Carbonate of Potassa in half a gallon of the Water. Sprinkle a little of the Water upon the Lime in an earthen vessel, and, the Lime being slaked, add the remainder of the Water. The liquors being immediately mixed together in a close vessel, shake them frequently until they are cold. Then set the mixture by, that the carbonate of lime may subside. Lastly, pour off the supernatant liquor, and keep it in a well-stopped green glass bottle.” *Lond.*

“Take of Carbonate of Potash (dry) *four ounces*; Lime, recently burnt, *two ounces*; Water *forty-five fluidounces*. Let the Lime be slaked and converted into milk of Lime with seven fluidounces of the Water. Dissolve the Carbonate in the remaining thirty-eight fluidounces of Water; boil the solution, and add to it the milk of Lime in successive portions, about an eighth at a time, boiling briskly for a few minutes after each addition. Pour the whole into a deep narrow glass vessel for twenty-four hours; and then withdraw with a syphon the clear liquid, which should amount to at least thirty-five fluidounces, and ought to have a density of 1.072.” *Ed.*

“Take of Carbonate of Potassa from Pearlash, fresh burnt Lime, each, *two parts*; Water *fifteen parts*. Sprinkle one part of the Water, previously heated, on the Lime, placed in an earthen vessel; and when it is slaked, mix the salt with it immediately, and then add the remainder of the Water. When the mixture has cooled, put it into a well stopped bottle, and, shaking it frequently, keep it for three days. When the carbonate of lime has subsided, decant the supernatant liquor, and keep it in green glass bottles, well stopped. The specific gravity of this solution is 1.080.” *Dub.*

The object of these processes is to separate carbonic acid from the carbonate of potassa, so as to obtain the alkali in a caustic state. This is effected by hydrate of lime; and the chemical changes which take place are most intelligibly explained by supposing the occurrence of a double decomposition. The lime of the hydrate of lime, by its superior affinity, combines with the carbonic acid, and precipitates as carbonate of lime; while the water of the hydrate unites with the potassa, and remains in solution as

hydrate of potassa. The proportion indicated by theory for this decomposition would be 69·27 of the dry carbonate to 28·5 of lime, or one eq. of each; but in practice it is found necessary to use an excess of lime. In the U. S. and Edinburgh formulæ the alkaline salt is treated with half its weight of lime; in the London, with eight-fifteenths; and in the Dublin, with its own weight; proportions, the lowest of which exceeds the theoretical quantity. The disadvantages of using a large excess of lime, as is done by the Dublin College, are the necessity of employing larger vessels, on account of the bulk of the materials, and the loss of a portion of alkaline solution which is retained by the spongy residuum. The proportion of water employed has a decided influence on the result. If the water be deficient in quantity, the decomposing power of the lime, on account of its sparing solubility, will be lessened; and more of it will be required to complete the decomposition of the carbonate, than if the solutions had been more dilute. The quantity ordered in the U. S., London, and Edinburgh formulæ is ample, but it is deficient in the Dublin process. Thus, taking the lime at the same quantity in each formula, the quantity of water directed is expressed by the following numbers nearly; 59 *Ed.*, 58 *U. S.*, 52 *Lond.*, and 22 *Dub.* Straining must not be used, as the operation causes a prolonged contact with the air, and risk of the absorption of carbonic acid, and is apt, moreover, to introduce organic matter into the solution derived from the strainer. The direction to keep the solution in green glass bottles is judicious; as white flint glass is slightly acted on.

As the solution of potassa is frequently made by the manufacturing chemist in considerable quantities, the following details, taken from Berzelius, of the best mode of conducting the process, may not be without their use. Dissolve one part of carbonate of potassa in from seven to twelve parts of water, in a bright iron vessel, and decant the solution after it has become clear by standing. Boil the solution in an iron vessel, and while it is boiling, add, at intervals, small quantities of slaked lime reduced to a thin paste with water; allowing the solution to boil a few minutes after each addition. One and a half parts of pure lime will be more than sufficient to decompose one part of the carbonate. When about half the hydrate of lime has been added, take out about a teaspoonful of the boiling solution, and after dilution and filtration through paper, test it by adding it to some nitric acid, or by mixing it with an equal bulk of lime-water. If the solution has not been completely freed from carbonic acid, the first reagent will cause an effervescence, and the second a milky appearance; in either of which events the addition of the lime must be continued as before, until the above mentioned tests give negative indications. In conducting the process, two advantages are gained by keeping the solution constantly boiling. One is that the carbonate of lime formed is in this way rendered granular and heavy, and more disposed to subside; and the other, that it prevents the precipitated carbonate from coalescing into a mass at the bottom of the vessel, an occurrence which causes the ebullition, when subsequently renewed, to take place imperfectly and by jerks. The process here described has been adopted in the last edition of the Edinburgh Pharmacopœia.

Properties, &c. Solution of potassa is a limpid, colourless liquid, without smell, and having an acrid, caustic taste, and alkaline reaction. It acts rapidly on animal and vegetable substances, and when rubbed between the fingers produces a soapy feel, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and, by union with oily and fatty bodies, forms soap. The officinal solution is never perfectly pure, but contains either some undecomposed carbonate, or free

lime, in addition to minute portions of sulphate of potassa, chloride of potassium, silica, and alumina, impurities usually present in the carbonate of potassa obtained from pearlash, which is used in its preparation. Undecomposed carbonate may be detected in the manner explained in the preceding paragraph, and free lime, by the production of a milky appearance on the addition of a few drops of carbonate of potassa, which serves to precipitate the lime as a carbonate. When saturated with nitric acid, it gives little or no precipitate with carbonate of soda, chloride of barium, or nitrate of silver. It is incompatible with acids, acidulous salts, and all metallic and earthy preparations held in solution by an acid; as also with all ammoniacal salts, and with calomel and corrosive sublimate. The official solutions of potassa vary in strength; the U. S. solution having the specific gravity of 1.056; the London, of 1.063; the Edinburgh, of 1.072; and the Dublin, of 1.080. These solutions are quite dilute; for, according to a table given by Dalton, a solution having the sp. gr. 1.06, contains only 4.7 per cent. of alkali. On account of its strong attraction for carbonic acid, the solution of potassa should be carefully preserved from contact with the air.

B.

Medical Properties and Uses. Solution of potassa is antacid, diuretic, and antilithic. It has been much employed in calculous complaints, under the impression that it has the property of dissolving urinary concretions in the kidneys and bladder; but experience has proved that the stone once formed cannot be removed by remedies internally administered, and the most that the alkaline medicines can effect, is to correct that disposition to the superabundant secretion of uric acid, or the insoluble urates, upon which gravel and stone often depend. For this purpose, however, the carbonated alkalies are preferable to caustic potassa, as they are less apt to irritate the stomach, and to produce injurious effects when long continued. It has been proposed to dissolve calculi by injecting immediately into the bladder the solution of potassa in a tepid state, and so much diluted that it can be held in the mouth; but this mode of employing it has not been found to answer in practice. This solution has also been highly recommended in lepra, psoriasis, and other cutaneous affections; and is said to have proved peculiarly useful in scrofula; but in all these cases it probably acts simply by its antacid property, and is not superior to the carbonate of potassa or of soda. Externally it has been used in a diluted state as a stimulant lotion in rachitis and arthritic swellings, and concentrated, as an escharotic in the bite of rabid or venomous animals. The dose is from ten to thirty minims, repeated two or three times a day, and gradually increased in cutaneous affections to one or two fluidrachms; but the remedy should not be too long continued, as it is apt to debilitate the stomach. It may be given in sweetened water or some mucilaginous fluid. Veal broth and table beer have been recommended as vehicles; but the fat usually present in the former, would be liable to convert it into soap, and the acid in the latter would neutralize it. In dyspeptic cases it may be associated with the simple bitters. In excessive doses it irritates, inflames, or corrodes the stomach. Oils and the milder acids, such as vinegar and lemon-juice, are the antidotes to its poisonous action. They operate by neutralizing the alkali.

It is employed pharmaceutically in the preparation of the Precipitated Sulphuret of Antimony (*U. S., Lond., Ed.*), Tartrate of Iron and Potassa (*U. S., Lond.*), Ethereal Oil (*U. S., Lond.*), Binoxide of Mercury (*Lond.*), Black Oxide of Mercury (*Dub.*), and Hydrated Oxide of Lead (*Lond.*).
Off. Prep. Potassa, *U. S., Lond., Ed., Dub.*; Potassa cum Calce, *Ed., Dub.*

W.

POTASSA. *U. S., Ed.* POTASSÆ HYDRAS. *Lond.* POTASSA CAUSTICA. *Dub.* Potassa. *Hydrate of Potassa.* *Caustic Potassa.*

"Take of Solution of Potassa a gallon. Evaporate the water rapidly, in a clean iron vessel, over the fire, till ebullition ceases, and the Potassa melts. Pour this into suitable moulds, and keep it, when cold, in well-stopped bottles." *U. S.*

The *London* formula is essentially the same with the above.

"Take any convenient quantity of Aqua Potassæ; evaporate it in a clean and covered iron vessel, increasing gradually the heat, till an oily-looking fluid remains, a drop of which, when removed on a rod, becomes hard on cooling. Then pour out the liquid upon a bright iron plate, and as soon as it solidifies, break it quickly, and put it into glass bottles secured with glass stoppers." *Ed.*

"Take of Water of Caustic Potassa any quantity. Evaporate it over the fire in a perfectly clean silver or iron vessel, until the ebullition shall have ceased, and the saline matter, on increasing the heat, shall remain perfectly at rest in the vessel. Pour out the liquified Potassa on a silver or iron plate, and, whilst concreting, cut it into pieces of a proper size, which are immediately to be introduced into a well-stopped bottle. The operator should carefully avoid the drops which are ejected from the vessel during the evaporation." *Dub.*

The concrete alkali, obtained by these processes, is the hydrate of potassa, sufficiently pure for medical purposes. The solution of the alkali freed from carbonic acid having been obtained by another formula (see *Liquor Potassæ*), the formation of the present preparation requires merely the evaporation of this solution, until the whole of its uncombined water is driven off. The evaporation is required to be performed in metallic vessels, as those of glass or earthenware are acted on by the alkali; and it should be completed as quickly as possible, in order to abridge the period during which the solution would be liable to absorb carbonic acid from the atmosphere. When poured out on a metallic plate, the cake, just as it concretes, may be marked with a knife in the directions in which it is to be divided, and when cold it readily breaks in those directions. A better plan, however, is to run the fused alkali into suitable moulds, as directed in the *U. S.* and *London* formulæ. These should be made of iron and have a cylindrical shape, which is the most convenient form of the alkali for the use of the surgeon. Green glass bottles with ground stoppers are the best adapted for preserving this preparation, as white flint glass is slightly acted on.

Properties, &c. In its official impure form, potassa is usually in sticks which have a fibrous fracture, a dingy gray or greenish colour, occasionally a bluish tint, and the peculiar odour of slaking lime. It is extremely caustic and very deliquescent, and dissolves in less than its weight of water. It is also readily soluble in alcohol. When exposed to a low red heat it melts, and at bright redness is volatilized. On account of its deliquescent property, and its strong attraction for carbonic acid, it requires to be kept in very accurately stopped bottles. In the state here described, the alkali always contains combined water as a part of its composition. It contains also several impurities, which, however, do not interfere with its medicinal value, such as sulphate of potassa, chloride and teroxide of potassium, sesquioxide of iron, lime, silica, alumina, and a portion of the alkali itself still in a carbonated state. The insoluble impurities, according to the *Edinburgh Pharmacopœia*, should not exceed 1.25 per cent. It may be freed from impurity by digestion in alcohol, which takes up only the pure hydrated alkali, evaporating the alcoholic solution to dryness, and

fusing the dry mass obtained. *Pure hydrate of potassa*, when thus procured, is usually called *alcoholic potassa*. It is generally in the form of flat white pieces, which are dry, hard, and brittle, and extremely caustic. Its other properties are similar to those of the impure hydrate above described. It may be discriminated from the other fixed alkalies (soda and lithia) by affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric acid, and a yellow one with chloride of platinum. The officinal potassa, apart from impurities, consists of one eq. of dry potassa 47·15, and one of water 9=56·15. Dry potassa is formed of one eq. of potassium 39·15, and one of oxygen 8=47·15. (See *Potassium*.)

B.

Medical Properties and Uses. This is the old *causticum commune acerrimum*, or strongest common caustic. It is a very powerful escharotic, quickly destroying the life of the part with which it comes in contact, and extending its action to a considerable depth beneath the surface. In this latter respect, it differs from the nitrate of silver or lunar caustic, to which it is, therefore, preferred for the purposes of forming issues and opening abscesses. It has been used for removing stricture of the urethra; but in consequence of its tendency to spread, it may, unless carefully applied, produce such a destruction of the lining membrane, as to open a passage for the urine into the cellular tissue, and thus involve the patient in danger. The most convenient mode of employing the caustic for the formation of an issue, is to apply to the skin a piece of linen spread with adhesive plaster, having a circular opening in its centre corresponding to the intended size of the issue, and then to rub upon the skin, within the opening, a piece of the caustic previously moistened at one end. The application is to be continued till the life of the part is destroyed, when the caustic should be carefully washed off by a wet sponge or wet tow, or neutralized by vinegar. The preparation is also employed for forming solutions of potassa of definite strength, whether for medicinal or pharmaceutic use. A solution of one drachm and a half of caustic potassa in two fluidounces of distilled water, is highly recommended by Dr. Hartshorne, of Philadelphia, as an application to the spine in tetanus. It may be applied by means of a sponge attached to the end of a stick, which should be drawn quickly along the back from the nape of the neck to the sacrum. It produces a very powerful rubefacient effect.

The U. S. Pharmacopœia employs caustic potassa in the preparation of the black oxide of mercury.

Off. Prep. Potassa cum Calce. *Lond.*

W.

POTASSA CUM CALCE. *Lond., Ed.* POTASSA CAUSTICA CUM CALCE. *Dub.* Potassa with Lime.

"Take of Hydrate of Potassa, Lime, each, *an ounce*. Rub them together, and keep them in a well-stopped vessel." *Lond.*

"Take *any convenient quantity* of Aqua Potassæ; evaporate it in a clean, covered iron vessel to one-third of its volume; add slaked Lime till the fluid has the consistence of firm pulp. Preserve the product in carefully covered vessels." *Ed.*

"Evaporate Water of Caustic Potassa to one-fourth; then add as much fresh burnt Lime, in powder, as will form a mass of the proper consistence, which is to be preserved in a well-stopped bottle." *Dub.*

The London preparation is a mere mixture of hydrate of potassa with lime, both in the dry state. The Edinburgh and Dublin Colleges employ a solution of potassa, which is first concentrated, and then thickened by the

addition of lime until the mixture becomes a pulpy mass, consisting of the mixed hydrates of potassa and lime.

The Edinburgh and Dublin "potassa with lime," like the officinal potassa, is used as a caustic; but it is more manageable than the latter preparation, owing to the presence of the lime, which renders it milder, slower in its operation, and less deliquescent, and causes it to spread less beyond the part intended to be affected. This preparation was formerly called *causticum commune mitius*, or milder common caustic. The London preparation is a powder, sometimes called *Vienna powder*, and is still slower in producing an eschar. It is prepared for use by being made up into a paste with a little alcohol. The paste is applied to the part to be cauterized for ten or fifteen minutes, and is conveniently limited in its operation by a piece of adhesive plaster, in the manner explained under potassa. This form of caustic has the advantage of not spreading its operation beyond the area to which it is applied. B.

POTASSÆ ACETAS. U.S., Lond., Ed., Dub. Acetate of Potassa.

"Take of Acetic Acid *a pint*; Carbonate of Potassa *a sufficient quantity*. Add the Carbonate of Potassa gradually to the Acetic Acid till it is saturated; then filter, and evaporate cautiously, by means of a sand-bath, until a dry salt remains. Keep this in closely stopped bottles." U.S.

"Take of Carbonate of Potassa *a pound*; Acetic Acid *twenty-six fluid-ounces*; Distilled Water *twelve fluidounces*. To the Acid, previously mixed with the Water, add the Carbonate of Potassa to saturation; then strain. Evaporate the liquor in a sand-bath, with a heat cautiously applied, until the salt is dried." Lond.

"Take of Pyroligneous Acid *a pint and a half* [Imperial measure]; Carbonate of Potash (dry) *seven ounces* or *a sufficiency*. Add the Carbonate gradually to the Acid till complete neutralization is accomplished. Evaporate the solution over the vapour-bath till it is so concentrated as to form a concrete mass when cold. Allow it to cool and crystallize in a solid cake; which must be broken up and immediately put into well-closed bottles." Ed.

"Take of Carbonate of Potassa from Crystals of Tartar *any required quantity*. Pour on it, by repeated additions, Distilled Vinegar of a *medium* heat, and in quantity about five times the weight of the salt. When the effervescence shall have ceased, and the liquor have been evaporated for some time, repeat the addition of Distilled Vinegar at intervals, until effervescence shall have completely ceased. Evaporate to dryness, and, by cautiously raising the heat liquefy the salt. When the salt has cooled, dissolve it in water, filter the solution, and boil it down, until, when removed from the fire, it shall form, on cooling, a mass of crystals, which should be perfectly white. Put these immediately into bottles which should be carefully stopped." Dub.

The process for forming acetate of potassa is a case of single elective affinity. The form of acid employed for generating the salt is the officinal acetic acid in the U.S. and London Pharmacopœias, pyroligneous acid in the Edinburgh, corresponding with the U.S. and London acetic acid, and distilled vinegar in the Dublin. (See page 781.) Distilled vinegar is not a proper material for forming this salt, on account of its containing organic matter, which gives the solution, when concentrated, a reddish or brownish colour. This colouring matter is got rid of in the Dublin process by fusing the salt, dissolving it in water, and concentrating the solution so that it may concrete into a mass on cooling. When this process is followed, great care

must be taken not to use too high a heat in effecting the fusion; otherwise part of the acetic acid will be decomposed, and a colourless salt will not be obtained. In the other formulæ, a pure acid being used, it forms, when saturated with the carbonate of potassa, a colourless solution. This is evaporated to dryness, according to the U. S. and London Pharmacopœias, and to such a degree as to concrete into a mass when cold, according to the Edinburgh. The quantity of carbonate necessary for saturation cannot be accurately determined beforehand, and, therefore, it is injudicious in the London College to attempt to fix it in the formula. A better plan is that of the U. S. formula, in which a sufficient quantity for saturation is directed to be taken, the exact amount to be determined in the process. The same plan is adopted by the Edinburgh College, with the addition of indicating about the quantity required. As a sufficiency of the carbonate is thus ordered, be it more or less, it would seem quite unnecessary for the College to direct that it should be *dry*. For drying the acetate of potassa Dr. Christison considers the heat of a vapour-bath too low, and that of a sand-bath apt to become too high. He, therefore, recommends the use, when operating on a small scale, of a bath of chloride of calcium. In conducting this process, it is best to have the solution always slightly acid; for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration.

Acetate of potassa may be obtained, also, by double decomposition between acetate of lead and sulphate of potassa. When thus procured it is very white and pure, but liable to the objection, for medical use, that it may possibly contain lead. Another method by double decomposition is between acetate of lime and sulphate of potassa; but when thus prepared the salt is apt to contain some of the alkaline sulphate.

Properties, &c. Acetate of potassa, when pure, is a white salt, perfectly neutral to test paper, unctuous to the touch, and possessing a warm, pungent, saline taste. When unskillfully prepared, it is apt to be more or less coloured. Its state of aggregation differs with the manner in which it is prepared. As obtained by evaporating the solution to dryness, agreeably to the directions of the U. S. and London Pharmacopœias, it is in the form of soft fibrous masses. As usually prepared and found in the shops, it has a foliated texture, which is given to it by fusion and cooling. On account of this appearance it was formerly called *foliated earth of tartar*. This salt is extremely deliquescent, and, if exposed to the air, becomes converted into a liquid of an oleaginous appearance. It is on account of this property that it must always be preserved in well stopped bottles. It dissolves in about half its weight of water, and twice its weight of alcohol. Any thing remaining undissolved by these menstrua is impurity. Heated above its point of fusion it is decomposed into acetone (see p. 782) and carbonate of potassa; the acetic acid being resolved into this volatile liquid and carbonic acid. When treated with sulphuric acid, acetic acid vapours are copiously evolved, and sulphate of potassa is formed. The most usual impurities contained in it are the sulphate and tartrate of potassa, chloride of potassium, and the salts of lead and copper. A soluble sulphate may be detected by chloride of barium; and chloride of potassium, or any soluble chloride, by nitrate of silver, added to a dilute solution. If tartrate of potassa be present, it will remain undissolved when the salt is acted on by alcohol. Lead and copper may be detected by sulphuretted hydrogen and ferrocyanuret of potassium; the former test producing with the lead a blackish, and the latter with the copper a brown precipitate. Since the introduction of the cheap method of obtaining pure acetic acid from wood, this salt has scarcely been subject to adulteration. Acetate of potassa is incompatible with the mineral acids,

which expel the acetic acid; with sulphate of soda and sulphate of magnesia; with corrosive sublimate and nitrate of silver; and with several other earthy and metallic salts. This salt exists in the juices of many plants, and especially in the sap of trees; and is the source of the carbonate of potassa existing in the ashes of wood. It consists of one eq. of acetic acid 51.48, one of potassa 47.15, and two of water 18=116.63.

Medical Properties and Uses. Acetate of potassa acts as a diuretic in doses of from a scruple to a drachm, and as a mild cathartic when given to the extent of two or three drachms. It is employed in dropsies, and often with good effect. The late Dr. Duncan considered it to be a medicine of great efficacy, and one of our best saline deobstruents. We have ourselves used it in dropsical affections, and can bear testimony to its powers. The acetate, ready prepared, being an expensive preparation, the salt, equally efficacious, may be made extemporaneously in the liquid form by saturating distilled vinegar with the carbonate of potassa. Two drachms of the carbonate, saturated with vinegar, will sometimes produce in hydropic cases ten or twelve stools, and a copious discharge of urine. (*Duncan.*) Acetate of potassa, like the other alkaline salts containing a vegetable acid, may be given in the uric acid diathesis, to render the urine alkaline; for the experiments of Wöhler have shown that the acid of these salts undergoes decomposition in the digestive and assimilating processes, while the alkali enters the current of the circulation. From the decided properties which this salt possesses of increasing the secretion of the kidneys, it was formerly called *sal diureticus* or *diuretic salt*.

POTASSÆ CARBONAS. *U.S., Lond., Ed.* POTASSÆ CARBONAS E LIXIVO CINERE. *Dub.* Carbonate of Potassa. Carbonate of Potassa from Pearlash.

“Take of Impure Carbonate of Potassa [pearlash] *three pounds*; Water *two pints and a half*. Dissolve the Impure Carbonate of Potassa in the Water, and filter the solution; then pour it into a clean iron vessel, and evaporate the water over a gentle fire till the solution thickens; lastly, remove it from the fire, and stir it constantly with an iron spatula till the salt granulates.” *U.S.*

“Take of Impure Carbonate of Potassa *two pounds*; Distilled Water *a pint and a half* [Imperial measure]. Dissolve the Impure Carbonate of Potassa in the Water, and strain; then pour off the solution into a proper vessel, and evaporate the Water that the liquor may thicken; afterwards stir it constantly with a spatula until the salt concretes. Carbonate of Potassa may be prepared more pure from the crystals of Bicarbonate of Potassa heated to redness.” *Lond.*

“Take of Pearlash, in coarse powder, cold Water, each, *one part*. Mix them by trituration, and macerate for a week, in a wide vessel, with occasional agitation. Then filter the lixivium, and evaporate it to dryness in a very clean silver or iron vessel. Towards the end of the evaporation, stir the saline mass constantly with an iron spatula. Having in this manner reduced it to a coarse powder, preserve it in close vessels. If the Pearlash is not sufficiently pure, roast it in a crucible until it becomes white, before dissolving it in the Water.” *Dub.*

The Edinburgh College, in the last edition of its Pharmacopœia, has removed carbonate of potassa from among the “Preparations,” and placed it in the Materia Medica list with this note. “Carbonate of potash not

quite pure, obtained by lixiviating, evaporating, and granulating by fusion and refrigeration the potashes [pearlash] of commerce."

The object of the above processes is to purify the impure carbonate of potassa or pearlash. This generally contains certain insoluble impurities, as well as small portions of sulphate and silicate of potassa, and chloride of potassium, as explained under another head. (See *Potassæ Carbonas Impurus*.) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are got rid of, as well as the greater part of the foreign salts, which being much less soluble than the carbonate of potassa, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of cold water, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor, obtained by decantation or filtration, is then evaporated to dryness. The different officinal processes are conducted very much in this way; cold water being employed, and equal weights of alkali and water being used in the Dublin formula, and about equal weights in the processes of the U.S. and London Pharmacopœias. The prolonged contact of the water with the salt, and the occasional stirring of the mixture, ordered by the Dublin College, are useful directions. In no case should the undissolved residue be washed with a fresh portion of water, as, by such a proceeding, the foreign salts, which it is the object of the process to separate, would be dissolved. Iron or silver vessels are directed, because these metals are not acted on by the alkali, while glass is attacked by it. In granulating the salt by stirring, it is better to keep it on the fire until the process is finished than to remove it the moment it thickens.

According to Berzelius, a more productive process for purifying pearlash, though the salt is not so pure as when obtained in the way just described, is to dissolve the impure salt in more than its weight of water, to evaporate the solution till it has the density of 1.52, and then to put it in a cool place, that the foreign salts, principally sulphate of potassa and chloride of potassium, may crystallize. The solution is then decanted, and evaporated to dryness.

Properties, &c. Carbonate of potassa, as found in the shops, is in the form of a coarse granular white powder, having a nauseous, alkaline taste, and acting as an alkali on vegetable colours. It is very soluble in water, dissolving in its weight of that liquid; but is insoluble in alcohol. It is extremely deliquescent, and hence a portion of it, exposed to the air for some time, attracts so much water as completely to dissolve into an oily liquid, called by the older chemists, *oleum tartari per deliquium*. On account of this property, carbonate of potassa should be kept in bottles with accurately ground stoppers. If exposed, in its usual state, to a red heat, it retains its carbonic acid, but loses about sixteen per cent. of water. When pure it is completely soluble in water; but, generally, a small insoluble portion is left of earthy matter. An aqueous solution, when saturated with an acid, slowly deposits a slightly gelatinous precipitate, derived from silica. The usual impurities are earthy matter, sulphate of potassa, chloride of potassium, and silica in the state, probably, of silicate of potassa. When dissolved in water and supersaturated with nitric acid, it affords a faint cloudiness with chloride of barium, and a slight precipitate with nitrate of silver; effects showing the presence of minute portions of a sulphate and of a chloride. If the indications of these tests are more decided, the salt is below the officinal standard of purity. It is incompatible with acids and acidulous salts, muriate and acetate of ammonia, lime-

water, chloride of calcium, sulphate of magnesia, alum, tartar emetic, nitrate of silver, ammoniated copper and ammoniated iron, sulphate of iron and tincture of chloride of iron, calomel and corrosive sublimate, acetate and subacetate of lead, and sulphate of zinc. It is not decomposed by tartrate of iron and potassa, and, therefore, may be associated with it in prescriptions.

Composition. Carbonate of potassa, after exposure to a red heat, is an anhydrous salt, consisting of one eq. of carbonic acid 22·12, and one of potassa 47·15 = 69·27. As obtained by the officinal formulæ, it is, according to Mr. Phillips, a sesquihydrate, consisting of two eqs. of carbonate, and three of water. B.

Medical Properties and Uses. Purified pearlsh is the form of carbonate of potassa usually employed in this country, where it is frequently, though incorrectly, called *salt of tartar*, the latter name being strictly applicable to the purer carbonate, obtained by decomposing cream of tartar. It is occasionally used as an antacid in dyspepsia, as a diuretic in dropsy, and as an antilithic in gravel attended with red deposits from the urine; but the purpose to which it is most commonly applied is the formation of the *neutral mixture* and *effervescing draught*. (See *Liquor Potassæ Citratis*.) It is worthy of observation, that its solution, on exposure to the air, or on the addition of an acid, deposits flocculi consisting of hydrate of silica, resulting from the decomposition of the silicated potassa, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbonic acid. Carbonate of potassa is also used with much advantage in some cases of jaundice, in which it probably operates by entering the circulation and directly exciting the hepatic function. It has enjoyed some popular reputation mixed with cochineal in whooping-cough, and is supposed by some, in common with other alkaline remedies, to operate favourably in those inflammations in which there is a disposition to the exudation of coagulable lymph, or the formation of false membranes. The dose is from ten to thirty grains, given in some aromatic water sweetened with sugar. In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours. The antidotes are the fixed oils and vegetable acids.

Carbonate of Potassa is used in the formulæ for Sulphuric Ether (*Lond., Dub.*), Spirit of Ammonia (*Lond.*), Aromatic Spirit of Ammonia (*U. S., Lond.*), and Fetid Spirit of Ammonia (*Lond.*).

POTASSÆ CARBONAS PURUS. *U. S.* POTASSÆ CARBONAS PURUM. *Ed.* POTASSÆ CARBONAS E TARTARI CRYSTALLIS. *Dub.* *Pure Carbonate of Potassa. Carbonate of Potassa from Crystals of Tartar. Salt of Tartar.*

“Take of Bitartrate of Potassa [cream of tartar] *two pounds*; Nitrate of Potassa *a pound*. Rub them separately into powder; then mix and throw them into a brass vessel heated nearly to redness, that they may

undergo combustion. From the residue prepare the Pure Carbonate of Potassa, in the manner directed for the Carbonate." *U. S.*

"Pure Carbonate of Potash may be most readily obtained by heating crystallized Bicarbonate of Potash to redness in a crucible, but more cheaply by dissolving Bitartrate of Potash in thirty parts of boiling Water, separating and washing the crystals which form on cooling, heating these in a loosely covered crucible to redness so long as fumes are discharged, breaking down the mass, and roasting it in an open crucible for two hours, with occasional stirring, lixiviating the product with Distilled Water, filtering the solution thus obtained, evaporating the solution to dryness, granulating the salt towards the close by brisk agitation, and heating the granular salt nearly to redness. The product of either process must be kept in well-closed vessels." *Ed.*

"Take of Crystals of Tartar *any quantity*. Heat them to redness in a silver crucible, loosely covered, until they cease to emit vapours. Reduce the residue to a coarse powder, and roast it for two hours in the same crucible, without a cover, stirring it frequently; then boil it with twice its weight of water for a quarter of an hour, and, after the requisite subsidence, pour off the clear liquor. Repeat this three times. Filter the mixed solutions, and evaporate them in a silver vessel. Granulate the residual salt by frequently stirring it while it is becoming dry, and then heat it to dull redness. Before it is perfectly cold, take it out of the vessel, and preserve it in well-stopped bottles." *Dub.*

The product of the above processes is a carbonate of potassa, purer than that described under the preceding head. In the U. S. formula the salts employed undergo decomposition by the deflagration to which they are subjected: the tartaric and nitric acids are totally decomposed, and sufficient carbonic acid is formed, as one of the products of their decomposition, to saturate the common base of the two salts, and thus to generate carbonate of potassa. The alkali, however, is mixed with a portion of redundant charcoal, which gives to it a black colour; and from its colour and use in this state it was formerly called *black flux*. It is freed from carbonaceous matter by solution in water, filtration, evaporation, and granulation.

The Dublin College forms this carbonate by incinerating the bitartrate without nitre; and this forms the second process of the Edinburgh Pharmacopœia. The tartaric acid, which consists of hydrogen, carbon, and oxygen, is decomposed, and gives rise, among other products, to carbonic acid, which combines with the potassa. The matter, after ignition, contains, besides carbonate of potassa, certain impurities derived from those pre-existing in the bitartrate. These are carbonate of lime, arising from the decomposition of tartrate of lime, alumina, silica, and minute portions of the oxides of iron and manganese; and, being all insoluble in water, are left behind when the mass is acted on by that liquid, the alkaline carbonate alone being taken up.

The London College does not recognise a separate preparation under the title of "pure carbonate of potassa," but, to the formula for preparing the ordinary carbonate, subjoins directions for obtaining the pure carbonate by igniting the bicarbonate. (See *preceding article*.) When thus prepared, the second equivalent of carbonic acid, and the water of crystallization of the bicarbonate are expelled, and nothing remains but the carbonate in a very pure state. This is a ready and eligible mode of obtaining a pure carbonate of potassa, and forms the first process given in the Edinburgh Pharmacopœia.

Properties, &c. Pure carbonate of potassa, obtained from cream of tartar or from the bicarbonate, differs from the same salt procured from pearl-

ash, only in containing fewer impurities. It was formerly called *salt of tartar*, in allusion to its source; but at present this name is familiarly applied to any pure carbonate of potassa, without reference to its mode of preparation. It may, indeed, be very much doubted whether the real salt of tartar is often kept in our shops; the ordinary carbonate as purified from pearlash being generally substituted for it, and answering every medicinal purpose that could be expected from the use of the purer salt.

Medical Properties and Uses. These are precisely the same with those of the carbonate of potassa described in the preceding article. The pure carbonate furnishes the best material for forming the solution of citrate of potassa, or neutral mixture.

Off. Prep. Liquor Potassæ Arsenitis, *U. S., Dub.*; Potassæ Acetas, *Dub.*; Potassæ Carbonatis Aqua, *Dub.* B.

LIQUOR POTASSÆ CARBONATIS. *U. S., Lond.* POTASSÆ CARBONATIS AQUA. *Dub.* *Solution of Carbonate of Potassa.*

"Take of Carbonate of Potassa *a pound*; Distilled Water, *twelve fluid-ounces*. Dissolve the Carbonate of Potassa in the Water, and filter the solution." *U. S.*

"Take of Carbonate of Potassa *twenty ounces*; Distilled Water *a pint* [Imperial measure]. Dissolve the Carbonate of Potassa in the Water, and strain." *Lond.*

"Take of Carbonate of Potassa from Crystals of Tartar *one part*; Distilled Water *two parts*. Dissolve and filter. The specific gravity of this solution is 1.320." *Dub.*

This is simply a solution of carbonate of potassa in water, and furnishes a convenient form for the administration of the salt. An ounce is dissolved in a fluidounce of water in the *U. S.* formula, and in an Imperial fluidounce in the London. This will be understood, when the fact is adverted to that the London pint contains twenty Imperial fluidounces. The London solution is somewhat stronger than that of the *U. S. Pharmacopœia*; because the Imperial fluidounce weighs a little less than a fluidounce, wine measure. Thus the sp. gr. of the London solution, is 1.473; of the *U. S.* solution, 1.446. The Dublin process differs in using the pure form of the carbonate and in furnishing a solution considerably weaker. This solution should be colourless and inodorous, and possess the general alkaline qualities of the salt from which it is formed. The dose of the *U. S.* or London solution is from ten minims to a fluidrachm, sufficiently diluted with water or other bland liquid.

Off. Prep. Potassæ Hydriodas, *Dub.* B.

POTASSÆ BICARBONAS. *U. S., Lond., Ed., Dub.* *Bicarbonate of Potassa.*

"Take of Carbonate of Potassa *four pounds*; Distilled Water *ten pints*. Dissolve the Carbonate of Potassa in the Water, and pass Carbonic Acid through the solution till it is fully saturated. Then filter, and evaporate the filtered liquor that crystals may form, taking care that the heat does not exceed 160°. Pour off the supernatant liquid, and dry the crystals upon bibulous paper. Carbonic Acid is obtained from Marble by the addition of dilute Sulphuric Acid." *U. S.*

"Take of Carbonate of Potassa *six pounds*; Distilled Water *a gallon* [Imperial measure]. Dissolve the Carbonate of Potassa in the Water; afterwards pass Carbonic Acid through the solution to saturation. Apply a gentle heat, so that whatever crystals have been formed may be again dissolved. Then set aside the solution, that crystals may be again formed; and, having poured off the liquor, dry them. Carbonic Acid is very easily

obtained from Chalk, rubbed to powder, and mixed with water to the consistence of a syrup, upon which Sulphuric Acid is then poured, diluted with an equal weight of water." *Lond.*

"Take of Carbonate of Potassa from Pearlash, *one part*; Distilled Water *two parts*. Dissolve, and expose the solution, in a suitable apparatus, to a current of Carbonic Acid gas, evolved from White Marble by the action of dilute Muriatic Acid, until the liquid becomes turbid. Then filter it, and again expose it to the stream of Carbonic Acid gas, until the alkali is saturated. Lastly, put the solution in a cool place, that crystals may form, which are to be dried without heat, and kept in a well-stopped bottle." *Dub.*

"Take of Carbonate of Potash *six ounces*; Carbonate of Ammonia *three ounces and a half*. Triturate the Carbonate of Ammonia to a very fine powder; mix with it the Carbonate of Potash; triturate them thoroughly together, adding by degrees a very little water, till a smooth and uniform pulp be formed. Dry this gradually at a temperature not exceeding 140° , triturating occasionally towards the close; and continue the desiccation till a fine powder be obtained, entirely free of ammoniacal odour." *Ed.*

In these processes, the monocarbonate of potassa, consisting of one eq. of acid and one of base, is combined with an additional equivalent of carbonic acid. In the U. S., London, and Dublin processes the combination is effected by passing a stream of this acid through a solution of the carbonate, so long as it is absorbed. The solution employed is directed of different strengths. In the U. S. formula, the distilled water taken is about three times the weight of the carbonate; in the London and Dublin processes, it is twice the weight of the latter. As the bicarbonate of potassa requires four times its weight of water to dissolve it, the quantity of water ordered in these processes would seem not to be sufficient to dissolve the new salt; unless it be assumed that the solution becomes heated in consequence of the reaction. The non-solution of the whole of the new salt is not material, in case filtration is not practised, which would remove part of the bicarbonate with the impurities. The London College omits filtration, applies a gentle heat to dissolve any crystals which may have formed, and allows them to form again more perfectly by the slow cooling of the solution. In conducting the process filtration is not necessary, provided the carbonate of potassa employed is perfectly pure; but the Pharmacopœias order the carbonate, as procured from pearlash, and when thus obtained it always contains silica. As, during the progress of the saturation, the silica is deposited, this should be got rid of by straining, conducted in such a way as to avoid the removal of a part of the bicarbonate. These two objects might, probably, be effected by heating the solution before filtration, taking care that the temperature does not exceed 160° . A heat thus regulated would keep the bicarbonate in solution, without risk of its decomposition. In the U. S. process filtration is performed after the saturation is completed; in the Dublin, so soon as the solution becomes turbid by the liberation of silica. If it be questionable whether the proportion of water used in the U. S. formula is sufficient, the lesser quantity ordered by the Dublin College must be quite inadequate to hold in solution the generated salt. On a small scale this process is best performed in a Wolfe's apparatus of three bottles; the first containing water, to wash the carbonic acid gas, the two other solutions of the carbonate. The bottles should be connected by means of wide tubes, to prevent their being obstructed by the crystals formed. On a large scale, the saturation is performed in strong vessels, into which the carbonic acid is driven under pressure. Sulphuric acid is always used by the manufacturing chemist for generating the carbonic acid; but for

small operations, muriatic acid, diluted with twice its bulk of water, is more convenient; inasmuch as it generates with the marble or chalk a soluble salt (chloride of calcium), which does not interfere with the extrication of the carbonic acid as the insoluble sulphate of lime does.

The formula of the Edinburgh Pharmacopœia is one newly introduced into that work, in place of the process by means of a stream of carbonic acid, formerly adopted. In this process carbonate of ammonia, in very fine powder, is thoroughly incorporated with carbonate of potassa, by the assistance of a little water, so as to form a uniform pulp, which is dried by a gentle heat. By the combined influence of the volatility of the ammonia, and the affinity of the carbonate of potassa for carbonic acid, the carbonate of ammonia is totally decomposed; its carbonic acid generating the bicarbonate with the potassa, and its ammonia being evolved during the drying of the pulp, which is thus reduced to the state of a fine powder. This process is alleged by Dr. Christison to be superior to the other process, "in point of economy, despatch, and certainty in small operations."

Mr. Brande reports the following proportions as suitable for the preparation of bicarbonate of potassa on the large scale: "100 lbs. of purified carbonate of potassa are dissolved in 17 gallons of water, which, when saturated with carbonic acid, yield from 35 to 40 lbs. of crystallized bicarbonate; 50 lbs. of carbonate of potassa are then added to the mother liquor, with a sufficient quantity of water to make up 17 gallons, and the operation repeated."

It is stated on the authority of Wöhler, that charcoal, when mixed with the carbonate, facilitates, by its porosity, in a remarkable degree, the formation of the bicarbonate. Thus he found that when crude tartar was charred in a covered crucible, and the carbonaceous mass, after having been slightly moistened with water, was subjected to a stream of carbonic acid, the gas was absorbed with great rapidity, and heated the mass so considerably, as to render it necessary to surround the vessel with cold water, to prevent the decomposition of the bicarbonate that had been formed. When the temperature diminished, the saturation was known to be completed. The mass was lixiviated in the smallest quantity of water, at the temperature of from 85° to 100°, and the solution, after filtration and cooling, deposited the greater part of the bicarbonate in fine crystals. (*Am. Journ. of Pharm.* x. 82, from the *Annalen der Physik und Chemie*.)

According to Berzelius, the cheapest method of obtaining the bicarbonate of potassa is to suspend a concentrated solution of the purified carbonate, contained in a stoneware dish, within a cask over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbonic acid, and, by absorbing it, crystallizes into bicarbonate in the course of five or six weeks. Distillers and brewers particularly are enabled with great facility to prepare this salt by suspending the alkaline solution in the fermenting tun. The salt in powder called *sal aëratum*, which is made principally in the New England States, is, we believe, prepared in this way. It is, however, not a perfect bicarbonate.

Properties, &c. Bicarbonate of potassa is in transparent, colourless, inodorous crystals, slightly alkaline to the taste and to test paper, permanent in the air, and having the shape of irregular eight-sided prisms with two-sided summits. It dissolves in four times its weight of cold water, and in five-sixths of its weight of boiling water, by which it is partially decomposed, and converted into sesquicarbonate. It is insoluble in alcohol. Exposed to a low red heat, it loses 30.7 per cent., comprising half its carbonic acid and the whole of its water of crystallization, and returns to the state

of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method is now adopted by the London College for obtaining the pure carbonate. Supersaturated with nitric acid, it should give a clear solution, the transparency of which is not disturbed by chloride of barium, nitrate of silver, or carbonate of soda. When a perfect bicarbonate, its solution, unless heated, does not precipitate a solution of sulphate of magnesia. This negative indication, however, cannot be depended upon as showing the absence of carbonate; for, according to Dr. Christison, no precipitate will be occasioned, even when fifty per cent. of this impurity is present. Calomel is not decomposed by it, and, when dissolved in 40 parts of water, it produces a white haze merely with a solution of corrosive sublimate, instead of the brick-red one caused by the carbonate. (*Ed. Pharm.*) Bicarbonate of potassa consists of two eqs. of carbonic acid 44·24, one of potassa 47·15, and one of water 9=100·39.

Medical Properties. The medicinal properties of this salt are the same as those of the carbonate, to which it is preferable on account of its milder taste, and greater acceptability to the stomach. The dose is from twenty grains to a drachm.

Off. Prep. Liquor Potassæ Effervescens, *Lond., Ed.*; Pulveres Effervescentes, *Ed.* B.

LIQUOR POTASSÆ EFFERVESCENS. *Lond.* POTASSÆ AQUA EFFERVESCENS. *Ed.* *Effervescing Solution of Potassa.*

“Take of Bicarbonate of Potassa *a drachm*; Distilled Water *a pint* [Imperial measure]. Dissolve the Bicarbonate of Potassa in the Water; and pass into it Carbonic Acid, compressed by force, more than is sufficient for saturation. Keep the solution in a well-stopped vessel.” *Lond.*

The Edinburgh formula is the same as the above.

This preparation may be considered as the bicarbonate of potassa dissolved in carbonic acid water. It is, however, altogether superfluous in this country, in consequence of the general introduction into the shops of carbonic acid water (artificial Seltzer water), which may be readily employed for dissolving any desired proportion of the bicarbonate, with the result of forming a much brisker preparation. This solution has the general sparkling qualities and acidulous taste of carbonic acid water; the alkaline taste being covered in a great measure by the large excess of carbonic acid. The after-taste is more purely saline than that of the corresponding preparation made with soda. (See *Liquor Sodæ Effervescens.*) B.

LIQUOR POTASSÆ CITRATIS. *U. S.* *Solution of Citrate of Potassa. Neutral Mixture.*

“Take of fresh Lemon-juice *half a pint*; Carbonate of Potassa *a sufficient quantity*. Add the Carbonate of Potassa gradually to the Lemon-juice till it is perfectly saturated; then filter. Or,

“Take of Citric Acid *half an ounce*; Oil of Lemons *two minims*; Water *half a pint*; Carbonate of Potassa *a sufficient quantity*. Rub the Citric Acid with the Oil of Lemons, and afterwards with the Water till it is dissolved; then add the Carbonate of Potassa gradually till the Acid is perfectly saturated; lastly, filter.” *U. S.*

These are equivalent preparations; the solution of citric acid flavoured with oil of lemons being intended as a substitute for fresh lemon-juice when this cannot be had. In both, the potassa of the carbonate unites with the citric acid, and the carbonic acid is liberated. A portion of the latter remains in the solution, and a portion escapes with effervescence. The result, therefore, is a solution of citrate of potassa in water impregnated with car-

bonic acid. When lemon-juice is employed, the solution has a greenish colour; but prepared with the pure acid it is colourless. A flocculent precipitate is, in either case, apt to exhibit itself in small quantity, owing to the silicate of potassa generally present as an impurity in the carbonate of potassa. This gives up its base to the citric acid, and the silica is deposited in the state of a hydrate. It is to separate this impurity that the solution is directed to be filtered. About 33 grains of pure and perfectly dry carbonate of potassa, or 45 grains of the hydrated salt found in the shops, are sufficient to saturate a fluidounce of good lemon-juice; but the strength of the juice is variable, and the carbonate is apt to absorb moisture from the air, so that precision as to quantities cannot be readily attained. Hence the propriety of the direction to add the alkaline carbonate to saturation. The point of saturation may be determined by the cessation of effervescence, the absence of either an acid or alkaline taste, and still more accurately by the test of litmus paper, which should not be rendered bright red by the solution, nor restored to its blue colour if previously reddened by an acid.

The *bicarbonate of potassa* has been sometimes employed instead of the carbonate to saturate the acid. It is recommended by its greater purity; and, as it contains no silicate of potassa, it produces no precipitate of hydrate of silica. But as the carbonate is less expensive, and the impurities which it contains are not such as affect its medicinal efficacy, it has been preferred in the arrangement of the officinal formula. About one-third more of the bicarbonate is required than of the dry carbonate to saturate the acid.

The inequality of strength in the lemon-juice renders the neutral mixture more or less uncertain; though, if the apothecary select ripe and sound fruit, and express the juice himself, the preparation will be found to approach sufficiently near a uniform standard for all practical purposes. Nevertheless, if the physician wish absolute precision, he may order the neutral mixture to be made with crystallized citric acid as directed in the second officinal formula; or he may pursue the following plan suggested in former editions of this work. Dissolve two drachms of bicarbonate of potassa in two fluidounces of water; saturate the solution with good fresh lemon-juice, and strain; and lastly add enough water to make the mixture measure six fluidounces. A fluidounce of this solution, containing the alkali in twenty grains of the bicarbonate, may be given for a dose.

Effervescing Draught. Under this name, the citrate of potassa is often prepared extemporaneously, and given in the state of effervescence. The most convenient mode of exhibition, is to add to a fluidounce of a mixture consisting of equal parts of lemon-juice and water, half a fluidounce of a solution containing fifteen grains of carbonate of potassa, or twenty grains of the bicarbonate. Should effervescence not occur, as sometimes happens, when the carbonate is used, in consequence of the weakness of the lemon-juice, more of the juice should be added; as, unless sufficient acid is present to neutralize the potassa, part of the carbonate passes into the state of bicarbonate, and the gas is thus prevented from escaping. A solution of citric acid of the strength of that directed in the officinal formula may be substituted for lemon-juice, if this is not to be had. The fifteen grains of carbonate of potassa above mentioned are scarcely sufficient to saturate the lemon-juice, if of ordinary strength; but a little excess of the acid renders the preparation more agreeable to the taste. Some prefer the bicarbonate in the preparation of the effervescing draught, because it will always effervesce with lemon-juice, no matter what may be the strength of the latter. But this is an objection. The carbonate serves, by the absence of effervescence, to indicate when the lemon-juice is very weak in acid; and

the defect may then be easily remedied by the addition of more juice. When the bicarbonate is used, if there should be a deficiency of acid, it is not discovered; and the patient takes a considerable portion of undecomposed bicarbonate, instead of the full quantity of citrate intended.

The *citrate of potassa* in substance has within a few years been introduced into notice, and is now kept in many shops. It is very readily obtained by evaporating to dryness a solution of citric acid saturated by carbonate of potassa. It is a deliquescent and very soluble salt, of difficult crystallization. Its solution in water was proposed by Mr. Scattergood as a substitute for the neutral mixture, which is liable to the disadvantage, when prepared with lemon-juice, of being of uncertain strength. According to Mr. Scattergood, fifty grains of it equal the amount of the salt contained in a fluidounce of ordinary lemon-juice saturated with potassa. (*Journ. of the Phil. Col. of Pharm.* v. 16.)

Medical Properties and Uses. The solution of citrate of potassa has long been used under the name of *neutral mixture*, *saline mixture*, or *effervescing draught*. It is an excellent refrigerant diaphoretic, adapted to almost all cases of fever with a hot dry skin, and especially to the paroxysms of our remittent and intermittent fevers. The *effervescing draught* is peculiarly useful. The carbonic acid serves to cover the taste of the citrate of potassa, and adds to the diaphoretic powers of the salt, its own cordial influence over the stomach. No preparation with which we are acquainted is equally efficacious in allaying irritability of stomach, and producing diaphoresis, in our remittent fevers. It is usually also very grateful to the stomach. In order to increase the sedative and diaphoretic properties of the neutral mixture, it is customary to add to it a portion of tartar emetic; and a little sweet spirit of nitre will be found an excellent adjuvant in fevers with nervous disturbance. Should the solution irritate the bowels, as occasionally happens, it may be combined with a little laudanum or solution of sulphate of morphia. Sugar may be added if desired by the patient.

The dose of the officinal solution is a tablespoonful or half a fluidounce, which should be somewhat diluted when taken. The whole of each effervescing draught, prepared as above stated, is to be taken at once. The solid citrate may be given in the quantity of twenty-five grains, dissolved in a fluidounce of water. Each dose should be repeated every hour, two, or three hours, according to the urgency of the symptoms. W.

POTASSÆ NITRAS PURIFICATUM. *Dub.* *Purified Nitrate of Potassa.*

“Take of Nitrate of Potassa *one part*. Dissolve it in *two parts* of boiling Water, filter the solution, and set it aside, so that, on cooling, crystals may form.” *Dub.*

The purified nitre of commerce is sufficiently pure for medicinal use; so that this formula of the Dublin College is entirely unnecessary. The properties of nitre, and the manner in which it is purified, have been fully explained under another head. (See *Potassæ Nitræs*.)

Off. Prep. Æther Nitrosus, *Dub.* B.

POTASSÆ SULPHAS CUM SULPHURE. *Ed.* *Sulphate of Potassa with Sulphur.*

“Take of Nitrate of Potash and Sulphur *equal parts*. Mix them thoroughly; throw the mixture in small successive portions into a red-hot crucible; and when the deflagration is over, and the salt has cooled, reduce it to powder, and preserve it in well closed bottles.” *Ed.*

When the mixture, indicated in this formula, is thrown into a red-hot crucible, each successive portion melts, and the sulphur floats on the surface of the nitre with the appearance of a brown oil, burns vividly, and gives rise to a copious evolution of sulphurous acid gas. The product of the deflagration is a grayish-white friable mass, intermixed apparently with undecomposed sulphur.

The nature of this preparation has not been well determined. On the supposition that it is the sulphate of potassa, mixed with a portion of sulphur, as the Edinburgh name implies, its formation may be thus explained. By the combined influence of the sulphur and of the heat employed, the nitric acid of the nitre is totally decomposed, and is thus enabled to furnish sufficient oxygen to convert a portion of the sulphur into sulphuric acid, which, as soon as formed, combines with the base of the nitre, to form the sulphate of potassa. This is left mixed with a portion of sulphur, which has escaped combustion; but the greater part of the latter undergoes ordinary combustion, and is dissipated as sulphurous acid fumes.

Supposing the saline matter to be a sulphate containing a little free sulphur; this combustible is evidently used in great excess; but whether this excess is necessary to obtain the exact preparation desired by the Edinburgh College, it is not easy to determine. The late Dr. Duncan ascertained that the product amounted only to four-tenths of the materials employed. It is, therefore, smaller than it ought to be, even supposing that the residue consisted of nothing but sulphate of potassa.

Dr. Duncan was of opinion that the preparation under consideration cannot be viewed as a sulphuretted sulphate, and for the following satisfactory reasons. In the first place, it is more soluble in water than sulphate of potassa, and forms a yellowish solution, the water leaving undissolved only a small residue of a black colour, which is not sulphur. In the second place, it exhales during solution a sulphurous smell, and its taste is sulphurous. These facts seem to show that a small portion of sulphite of potassa is present in the preparation, or at least some sulphurous acid in a state of loose combination. It does not yield sulphuretted hydrogen on the addition of an acid, and is not precipitated by the salts of lead. These characters are inconsistent with the opinion of Mr. John Mackay, of Edinburgh, who believes that this preparation contains sulphuret of potassium. (See his remarks on it, in the *Pharm. Journ. and Trans.* for Jan. 1842.)

Properties, &c. This salt has an acid and sulphurous taste, and an acid reaction with test paper. When pulverized, it yields a pale yellowish-white powder. It is soluble in eight times its weight of cold water. It is, however, not a uniform preparation; different specimens, apparently prepared with equal care, exhibiting some points of difference in properties. It was called by the earlier chemists, *sal polychrestus Glaseri* or *sal polychrest*. Its other properties coincide generally with those of sulphate of potassa, which may be considered as its basis.

Medical Properties and Uses. The medical effects of this preparation differ but little, if at all, from those of sulphate of potassa. Its action on the system is stated by Dr. Duncan to resemble that of the sulphurous mineral waters which contain a portion of neutral salt. The dose is from half a drachm to a drachm. B.

POTASSÆ BISULPHAS. *Lond., Ed., Dub.* Bisulphate of Potassa.

“Take of the Salt which remains after the distillation of Nitric Acid *two pounds*; Sulphuric Acid *a pound*; boiling Water *six pints* [Imperial mea-

sure]. Dissolve the Salt in the Water, and add the Acid to it, and mix. Lastly, boil down the solution, and set it aside that crystals may form.”

London.

The Edinburgh formula is the same with the London, the sulphuric acid being merely taken by measure, equivalent to a pound by weight.

“Take of commercial Sulphuric Acid *two parts*; Carbonate of Potassa from Pearlash *a sufficient quantity*; Water *six parts*. Mix one part of the Sulphuric Acid with the Water, and saturate the mixture with the Carbonate of Potassa; then add the other part of the Acid to the liquor, and evaporate it, so that on cooling crystals may form.” *Dub.*

The Dublin process for forming this bisalt is more precise than those of the London and Edinburgh Colleges, but at the same time less economical. The object being to obtain a salt, containing twice as much sulphuric acid as exists in the neutral sulphate, it is plain that by dividing the acid employed into two equal parts, and saturating one of these parts with potassa, the resulting neutral sulphate must be converted into a bisulphate by the addition of the other part. By this process a pure bisulphate cannot be obtained in crystals. If the attempt be made to procure them by allowing a moderately concentrated solution to cool, crystals of neutral sulphate will be chiefly deposited. In order to get the bisulphate pure, the solution must be so far concentrated as to form on cooling a uniform crystalline mass. In explaining the other formulæ, it is only necessary to recall to the reader's attention, a part of the explanations given under the head of *Nitric Acid*. It was there stated, that for the proper decomposition of nitre, for the purpose of obtaining nitric acid, it is necessary to use two eqs. of sulphuric acid to one of the salt. Consequently, the salt which remains after the distillation of nitric acid is really a bisulphate, and would seem only to require to be dissolved, and the solution filtered and duly evaporated, in order to obtain the salt in crystals. But Mr. Phillips states, that when the bisulphate of potassa is dissolved in water, and the solution is allowed to crystallize, some sulphate and much sesquisulphate are obtained instead of bisulphate, owing to the water retaining a part of the excess of acid in solution. This result is prevented by the sulphuric acid directed to be added by the London and Edinburgh Colleges, and, consequently, the real bisulphate is obtained in crystals.

Properties, &c. Bisulphate of potassa is a white salt, having the form of a right rhombic prism, so flattened as to be tabular, and a bitter and extremely acid taste. It is soluble in twice its weight of cold water, and in less than its weight of boiling water. Alcohol does not dissolve it, but when added to an aqueous solution, precipitates the neutral sulphate. Exposed to the air, it effloresces slightly on the surface, and, when moderately heated, readily melts, and runs like oil. At a red heat, it loses water and the excess of acid, and is reduced to the state of neutral sulphate. From its excess of acid, it acts precisely as an acid on the carbonates, causing them to effervesce. It is incompatible with alkalies, earths, and their carbonates, with many of the metals, and most oxides. This salt was formerly called *sal enixum*. It consists of two eqs. of sulphuric acid 80·2, one of potassa 47·15, and two of water 18=145·35.

Medical Properties and Uses. Bisulphate of potassa unites the properties of an aperient with those of a tonic, and may be given in cases of constipation with languid appetite, such as often occur in convalescence from acute diseases. Dr. Paris states that it forms a grateful adjunct to rhubarb. It answers, also, according to Dr. Barker, for preparing an aperient effervescing draught at little expense. Equal weights, a drachm for instance, of

the bisulphate and of carbonate of soda, may be dissolved separately, each in two fluidounces of water, then mixed, and taken in the state of effervescence. The dose of the bisulphate is one or two drachms. B.

POTASSÆ TARTRAS. *U. S., Lond., Ed., Dub.* Tartrate of Potassa. Soluble Tartar.

"Take of Carbonate of Potassa *sixteen ounces*; Bitartrate of Potassa [cream of tartar] in fine powder, *three pounds*, or a sufficient quantity; boiling Water *a gallon*. Dissolve the Carbonate of Potassa in the Water; then gradually add the Bitartrate of Potassa to the solution till it is perfectly saturated, and boil. Filter the liquor, evaporate it until a pellicle forms, and set it aside to crystallize. Pour off the liquid, and, having dried the crystals on bibulous paper, keep them in closely stopped bottles." *U. S.*

"Take of Bitartrate of Potassa, powdered, *three pounds*; Carbonate of Potassa *sixteen ounces*, or a sufficient quantity; boiling Water *six pints* [Imperial measure]. Dissolve the Carbonate of Potassa in the boiling Water; then add the Bitartrate of Potassa, and boil. Strain the liquor, and afterwards boil it down till a pellicle appears, and set it aside that crystals may form. The liquor being poured off, dry these, and again evaporate the liquor that crystals may form." *Lond.*

The Edinburgh process is the same as the London.

"Take of Carbonate of Potassa from Pearlash *five parts*; Bitartrate of Potassa *fourteen parts*; boiling Water *forty-five parts*. Add gradually the Bitartrate of Potassa, in very fine powder, to the Carbonate of Potassa, dissolved in the Water. Filter the solution through paper, and evaporate it, so that on cooling crystals may form." *Dub.*

In these processes, the excess of acid in the bitartrate is saturated by the potassa of the carbonate, the carbonic acid is extricated with effervescence, and the neutral tartrate of potassa is obtained. On account of the greater solubility of the carbonate than of the bitartrate, the former is first dissolved, and the latter added to the solution to full saturation. As the bitartrate is gradually added, the mutual action of the salts should be promoted by constant stirring; and the addition should be continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified quantity of the bisalt; since from its variable quality, it is impossible to adjust precisely the proportion applicable to all cases. It is necessary that the solution should be exactly neutral, or a little alkaline; and hence, if inadvertently too much bitartrate has been added, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered in order to separate the tartrate of lime, which appears in white flocks, and which is always present in cream of tartar as an impurity. The evaporated liquor should then be placed in *warm* earthenware vessels, to ensure a slow refrigeration; and after remaining at rest for several days, the crystals begin to form. In order that the crystallization should proceed favourably, it is necessary according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in any part of the process; as this metal is apt to discolour the salt.

Tartrate of potassa is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid in the bitartrate is neutralized by means of carbonate of lime. This generates an insoluble tartrate of lime, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum*.)

Properties, &c. Tartrate of potassa, prepared according to the official processes, is in white crystals, which are slightly deliquescent, and usually in the form of irregular six-sided prisms with dihedral summits. Its taste is saline and bitter. It dissolves in about twice its weight of cold water, and in much less boiling water, and is nearly insoluble in alcohol. Exposed to heat it undergoes fusion, swells up, blackens, and is decomposed; being converted into carbonate of potassa. For medicinal use, it should always be crystallized; but as it ordinarily occurs in the shops, it is in a white granular powder, obtained by evaporating the solution to dryness, while it is constantly stirred. In this state it is said to require four times its weight of water for solution. It is never purposely adulterated; but if it be obtained by evaporation to dryness, it is liable to contain an excess of carbonate or of bitartrate of potassa, when it will have either an alkaline or acid reaction. It is decomposed by all the strong acids, and many acidulous salts, which cause the precipitation of minute crystals of bitartrate of potassa, by abstracting one eq. of alkali from two of the salt. Acetate of lead occasions a white precipitate of tartrate of lead, distinguishable from sulphate of lead by being wholly soluble in diluted nitric acid. Tartrate of potassa is composed of one eq. of tartaric acid 66.48 , and one of potassa $47.15 = 113.63$. According to Berzelius, the crystals contain no water of crystallization.

Medical Properties and Uses. Tartrate of potassa is a mild cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to febrile diseases, and is occasionally combined with senna, the griping effects of which it has a tendency to obviate. The dose is from a drachm to an ounce, according to the degree of effect desired.

B.

POTASSII BROMIDUM. *Lond.* Bromide of Potassium.

“Take of Bromine *two ounces*; Carbonate of Potassa *two ounces and a drachm*; Iron Filings *an ounce*; Distilled Water *three pints* [Imperial measure]. First add the Iron, and afterwards the Bromine, to a pint and a half of the Distilled Water. Set them by for half an hour, frequently stirring them with a spatula. Apply a gentle heat, and when a greenish colour occurs, pour in the Carbonate of Potassa dissolved in the remainder of the Water. Strain, and wash what remains in two pints [Imperial measure] of boiling Distilled Water, and again strain. Evaporate the mixed liquors, so that crystals may form.” *Lond.*

In the first step of this process, a solution of bromide of iron is formed; and this, by the addition of the solution of carbonate of potassa, is decomposed so as to generate carbonate of the protoxide of iron which precipitates, and bromide of potassium in solution. By straining, the precipitated carbonate is separated, and from the strained liquor crystals of bromide of potassium are obtained by due evaporation.

Properties, &c. Bromide of potassium is a permanent, anhydrous, colourless salt, crystallizing in cubes or quadrangular prisms, and having a pungent, saline taste, similar to that of common salt, but more acrid. It is very soluble in cold water, more so in hot, and but slightly soluble in alcohol. When heated it decrepitates, and, at a red heat, fuses without decomposition. The following characters are given of bromide of potassium by the London College. “Totally soluble in water. It does not alter the colour of litmus or turmeric. Chloride of barium throws down nothing from the solution. Sulphuric acid and starch added together render it yellow. Subjected to heat it loses no weight. Ten grains of this salt

decompose just 14.28 grains of nitrate of silver, and precipitate a yellowish bromide of silver, which is dissolved by ammonia, and but very sparingly by nitric acid." The object of adding sulphuric acid along with the starch is to set free the bromine. If the salt decomposes more nitrate of silver than is above stated, its saturating power is greater than it should be, and the presence of a chloride, probably of potassium or sodium, may be suspected. Bromide of potassium is incompatible with acids, and with acidulous and metallic salts. It consists of one eq. of bromine 78.4, and one of potassium 39.15 = 117.55.

Medical Properties. Bromide of potassium is deemed alterative and resolvent. In 1828, Pourché used it with benefit, both internally and in the form of ointment, in the treatment of bronchocele and scrofula. It was introduced into the London Pharmacopœia of 1836, in consequence of the favourable results obtained by Dr. Williams, of London, from its use as an internal remedy in several cases of enlarged spleen. It may be given in the form of pill or in sweetened water, in doses of from three to ten grains, three times a day. In irritable conditions of the bowels it is apt to occasion diarrhœa, to obviate which effect it may be necessary to give opium. The ointment may be made by mixing from a scruple to two drachms of the bromide with an ounce of lard. Of this from half a drachm to a drachm may be rubbed on a scrofulous tumour, or other part where its local action is desired, once in twenty-four hours.

POTASSII CYANURETUM. U. S. *Cyanuret of Potassium.*

"Take of Ferrocyanuret of Potassium, in powder, *eight ounces*; Distilled Water *six fluidounces*. Expose the Ferrocyanuret to a moderate heat until it becomes nearly white, and is wholly deprived of its water of crystallization. Put the residue in an earthen retort, with the beak loosely stopped, and expose it to a red heat for two hours, or till gas ceases to be disengaged. Withdraw the retort from the fire, close the orifice with lute, and then let the whole remain until quite cold. Break the retort, remove the black mass, reduce it to coarse powder, introduce it into a bottle of the capacity of twelve fluidounces, and then add the Distilled Water. Agitate the mixture occasionally for half an hour, throw it on a filter, evaporate the filtered solution rapidly to dryness, and keep the dry mass in a closely stopped bottle." U. S.

In order to understand the process adopted for obtaining this new official of the U. S. Pharmacopœia, it is necessary to bear in mind that the ferrocyanuret of potassium consists of two eqs. of cyanuret of potassium, one of cyanuret of iron, and three of water. The salt is first deprived of its water of crystallization by exposure to a moderate heat, and then calcined at a red heat for two hours, in order to decompose the cyanuret of iron. The product of the calcination is a black, porous mass, consisting of cyanuret of potassium, mixed with carburet of iron and charcoal. As the cyanuret is very prone to absorb oxygen, especially when hot, whereby it is decomposed, atmospheric air is excluded from the retort, while it is cooling, by luting its orifice. When the whole is cold, the black mass is reduced to coarse powder, and exhausted by cold distilled water, which dissolves the cyanuret of potassium and leaves the carburet of iron and charcoal behind. The filtered liquor, therefore, is an aqueous solution of cyanuret of potassium, which is obtained in a solid state, by a rapid evaporation to dryness. During the evaporation, a small portion of the cyanuret is decomposed, attended with the evolution of ammonia, and the production of formiate of potassa. A portion of this salt, therefore, contaminates the cyanuret, as obtained by this process; but the quantity is too small to interfere with its

medicinal action. The decomposition here referred to takes place between one eq. of cyanuret of potassium and four of water, and is represented by the following equation in which the cyanogen is expressed by its full symbol C_2N , and formic acid by C_2HO_3 ;— $K_2C_2N + 4HO = NH_3 + KO, C_2HO_3$. This decomposition is avoided by exhausting the black mass with boiling alcohol of 60 per cent. (0.896) instead of water. The alcoholic solution, by evaporation to a pellicle, lets fall the salt, upon cooling, as a crystalline precipitate, perfectly white and pure.
